- a) 5–20 mg/kg per day PO, may be given once daily or divided and given twice daily (q12h). Treatment should continue for at least 2–3 days beyond cessation of clinical signs, to a maximum duration of therapy is 30 days. (Package insert; *Baytril*®—Bayer)
- b) For sepsis: 5–20 mg/kg IV q12h (Hardie 2000)
- c) For skin, urinary infections: 2.5–5 mg/kg PO q12h for 7–14 days;

For deep pyodermas, complicated urinary infections: 5 mg/kg PO once daily (q24h) for 7–14 days (treatment may be required for 10–12 weeks for deep pyoderma, especially in German shepherds);

For lower respiratory tract infections: 5–10 mg/kg PO once daily (q24h) for 7–84 days;

For prostate infections: 5 mg/kg PO twice daily (q12h) for 7–14 days;

For histiocytic ulcerative colitis: 5 mg/kg PO twice daily (q12h) for 21–90 days;

For hemotropic mycoplasmosis: 5 mg/kg PO, IM q12h for 7–14 days;

For systemic orthopedic infections: 5–11 mg/kg PO, IV, IM, SC q12h for 10 days;

For *Pseudomonas* infections in soft tissues: 11–20 mg/kg PO, IM, SC q12h for 7 days minimum, treat as long as necessary;

For bacteremia, sepsis: 11 mg/kg PO, IV, IM, SC q12h for as long as necessary. (Greene, Hartmann et al. 2006)

■ CATS:

For susceptible infections:

- a) 5 mg/kg per day PO, may be given once daily or divided and given twice daily (q12h). Treatment should continue for at least 2–3 days beyond cessation of clinical signs, to a maximum duration of therapy is 30 days. (Package insert; Baytril®—Bayer)

■ HORSES:

Note: Usage of enrofloxacin in horses remains somewhat controversial. While there has been much discussion regarding the potential for cartilage abnormalities or other arthropathies in horses, objective data are lacking. At present, however, enrofloxacin probably should only be used in adult horses when other antibiotics are inappropriate. If using Baytril® injection orally in horses, it can be very irritating to the mouth. This may be alleviated by coating the liquid with molasses or preparing a gel (below) and rinsing the horse's mouth with water after administration.

An oral gel formulated from the bovine injectable product has been described (Epstein, Cohen et al. 2004). 100 mL of the 100 mg/mL bovine injection (Baytril® 100) is used. Stevia (0.35 g) is mixed with approximately 15 mL of liquid enrofloxacin until dissolved. Apple flavoring 0.6 mL is added until dissolved. Sodium carboxymethylcellulose (2 g) is sprinkled over the mixture and stirred until incorporated. Immediately begin gradually adding the remaining enrofloxacin (85 mL) before the mixture solidifies. Approximate concentration is 100 mg/mL. Stable for up to 84 days if kept in the refrigerator and protected from light.

- a) 7.5 mg/kg PO or IV once daily for susceptible respiratory infections (Ainsworth and Hackett 2004)
- b) Using the compounded gel as described above. 7.5 mg/kg PO once daily. Horses should be fasted for 11–14 hours prior to dosing and for 1–2 hours after dosing, but should have access to water. Rinse horse's mouth with water after dosing to reduce risks for oral ulceration. (Epstein, Cohen et al. 2004)

■ CATTLE:

- a) Enrofloxacin (Baytril® 100) is approved for the treatment of bovine respiratory disease associated with *Pasteurella haemolytica*, *Pasteurella multocida*, and *Haemophilus sommus*. It is administered by injection and is intended for the treatment of individual animals. The labeled dosage is: 2.5–5 mg/kg SC once daily for 3–5 days or 7.5–12.5 mg/kg SC once. The product is prescription only and is not for use in cattle intended for dairy production or in veal calves. Animals in-

tended for human consumption must not be slaughtered within 28 days from the last treatment. Extralabel use of fluoroquinolones in food animals is prohibited by the FDA.

■ FERRETS:

For susceptible infections:

- a) 10–20 mg/kg PO, IM, SC twice daily (Williams 2000)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: 5 mg/kg PO, SC, IM or IV q12h for 14 days. Drug of choice for *Pasteurella*. If giving SC, dilute or skin may slough. Do not give injectable product PO because it is very unpalatable (Ivey and Morrissey 2000)
- b) Hedgehogs: 5–10 mg/kg PO or SC q12h (Smith 2000)
- c) Chinchillas: 5–10 mg/kg PO, IM q12h (Hayes 2000)
- d) For mycoplasmal pneumonia in mice and rats: 10 mg/kg PO twice daily with doxycycline (5 mg/kg PO twice daily) (Burke 1999)
- e) Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats: 5–10 mg/kg PO or IM q12h or 5–20 mg/kg PO or SC q24h. In drinking water: 50–200 mg/liter for 14 days. Do not use in young animals. (Adamcak and Otten 2000)

■ CAMELIDS:

For susceptible infections in alpacas:

- a) 5 mg/kg SC or 10 mg/kg PO once daily (Gandolf, Papich et al. 2005)

■ BIRDS:

For susceptible gram-negative infections:

- a) Ratites: 1.5–2.5 mg/kg PO or SC twice daily. Drinking water: 10% solution, 10 mg/kg for 3 days; 5 mg/kg IM (IM injections cause severe muscle necrosis) twice daily for 2 days (Jenson 1998)
- b) 15 mg/kg PO, or IM or 250 mg/L of drinking water (Bauck and Hoefer 1993)

A method to make a 10.2 mg/mL oral suspension of enrofloxacin has been described: Make a stock solution of "HMC 0.15%" by mixing 7.5 mL of *Lubrivet*® with 92.5 mL of water. Crush three (3) whole 68 mg tablets with a "pinch" of citric acid. Add crushed mixture to a dispensing vial and 15 mL of "HMC 0.15%." Shake well to dissolve tablet coating; add a sufficient quantity of "HMC 0.15%" to a total of 20 mL and allow to stand at room temperature for 30 minutes to allow tablet coating to completely dissolve. Shake well before use and keep refrigerated. A 14-day expiration date has been assigned. By crushing six (6) tablets, a 20.4 mg/mL suspension may be compounded using the same technique.

■ REPTILES:

For susceptible respiratory infections for most species:

- a) 5 mg/kg IM every 5 days for 25 days; For chronic respiratory infections in tortoises: 15 mg/kg IM every 72 hours for 5–7 treatments (Gauvin 1993)

Monitoring

- Clinical efficacy
- Adverse effects
- In cats, monitor for mydriasis and/or retinal changes.

Client Information

- Do not crush film-coated tablets, as drug is very bitter tasting
- Animals should have access to water at all times
- Do not exceed dosage recommendations in cats; blindness can occur

Chemistry/Synonyms

A fluoroquinolone antibiotic, enrofloxacin occurs as a pale yellow, crystalline powder. It is slightly soluble in water. Enrofloxacin is related structurally to the human-approved drug ciprofloxacin (enrofloxacin has an additional ethyl group on the piperazinyl ring)

Enrofloxacin may also be known as: Bay-Vp-2674 or *Baytril*®.

Storage/Stability/Compatibility

Unless otherwise directed by the manufacturer, enrofloxacin tablets should be stored in tight containers at temperatures less than 30°C. Protect from strong UV light. Enrofloxacin has been reported to be soluble and stable in water, but solubility is pH dependent and altering the pH of the commercially available injections can cause precipitation.

The canine-approved product (2.27%) for IM injection should be stored protected from light; do not freeze.

The cattle-approved product (10%) injectable solution should be stored protected from sunlight. It should not be refrigerated, frozen or stored above 40°C (104°F). If exposed to cold temperatures, precipitation may occur; to redissolve, warm and then shake the vial.

Injectable enrofloxacin must not be mixed with, or come into contact with any IV solution containing magnesium (*e.g.*, *Normosol-R*, *Plasmalyte-R*, -A, or -56); morbidity and mortality secondary to micro-precipitants lodging in patient lungs have been reported.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Enrofloxacin Tablets (Film-Coated) & Oral Taste Tablets: 22.7 mg, 68 mg, 136 mg; *Baytril*® (Bayer Corp); (Rx). Approved for use in dogs and cats.

Enrofloxacin Injection: 22.7 mg/mL (2.27%) in 20 mL vials; *Baytril*® (Bayer Corp); (Rx). Approved for use in dogs.

Enrofloxacin Injection: 100 mg/mL in 100 mL and 250 mL bottles. Approved for use in cattle only. Not for use in cattle intended for dairy production or in calves to be processed for veal. Any extra-label use in food animals is banned by the FDA. Slaughter Withdrawal = 28 days when used as labeled. A withdrawal period has not been established in pre-ruminating calves. *Baytril 100*® (Bayer); (Rx)

HUMAN-LABELED PRODUCTS: None.

Note: Use of enrofloxacin by humans cannot be recommended due to a high degree of CNS effects.

EPHEDRINE SULFATE

(*e-fed-rin*)

**SYMPATHOMIMETIC BRONCHODILATOR/
VASOPRESSOR**

Prescriber Highlights

- ▶ Sympathomimetic used primarily for oral treatment of urinary incontinence & topically for nasal uses
- ▶ Contraindications: Severe CV disease, especially with arrhythmias
- ▶ Caution: Patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders or hypertension
- ▶ Adverse Effects: CNS stimulation, tachycardia, hypertension, or anorexia
- ▶ Excreted into milk, may affect neonates

Uses/Indications

Ephedrine is used chiefly for the treatment of urethral sphincter hypotonus and resulting incontinence in dogs and cats. It has also been used in an attempt to treat nasal congestion and/or bronchoconstriction in small animals. It can also be used parenterally as a pressor agent in the treatment of shock or anesthesia-associated hypotension.

Pharmacology/Actions

While the exact mechanism of ephedrine's actions are undetermined, it is believed that it indirectly stimulates both alpha-, beta₁-, beta₂-adrenergic receptors by causing the release of norepinephrine. Prolonged use or excessive dosing frequency can deplete norepinephrine from its storage sites and tachyphylaxis (decreased response) may ensue. Tachyphylaxis has not been documented in dogs or cats, however, when used for urethral sphincter hypotonus.

Pharmacologic effects of ephedrine include: increased vasoconstriction, heart rate, coronary blood flow, blood pressure, mild CNS stimulation, and decreased bronchoconstriction, nasal congestion and appetite. Ephedrine can also increase urethral sphincter tone and produce closure of the bladder neck; its principle veterinary indications are as a result of these effects.

Pharmacokinetics

Ephedrine is rapidly absorbed after oral or parenteral administration. Although not confirmed, ephedrine is thought to cross both the blood-brain barrier and the placenta. Ephedrine is metabolized in the liver and excreted unchanged in the urine. Urine pH may significantly alter excretion characteristics. In humans: at urine pH of 5, half-life is about 3 hours; at urine pH of 6.3, half-life is about 6 hours.

Contraindications/Precautions/Warnings

Ephedrine is contraindicated in patients with severe cardiovascular disease, particularly with arrhythmias. Ephedrine should be used with caution in patients with glaucoma, prostatic hypertrophy, hyperthyroidism, diabetes mellitus, cardiovascular disorders or hypertension.

When administered IV, administration rate should not exceed 10 mg/minute (in humans); it is suggested to scale the rate for veterinary patients.

Adverse Effects

Most likely side effects include restlessness, irritability, tachycardia, or hypertension. Anorexia may be a problem in some animals.

Reproductive/Nursing Safety

Ephedrine's effects on fertility, pregnancy or fetal safety are not known. Use with caution during pregnancy. The drug is excreted in milk and may have deleterious effects on nursing animals. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Ephedrine is excreted in milk. If ephedrine is absolutely necessary for the dam, consider using milk replacer.

Overdosage/Acute Toxicity

Clinical signs of overdosage may consist of an exacerbation of the adverse effects listed above or, if a very large overdose, severe cardiovascular (hypertension to rebound hypotension, bradycardias to tachycardias, and cardiovascular collapse) or CNS effects (stimulation to coma) can be seen.

If the overdose was recent, empty the stomach using the usual precautions and administer charcoal and a cathartic. Treat clinical signs supportively as they occur.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ephedrine and may be of significance in veterinary patients:

- **ALPHA-BLOCKERS** (e.g., **phentolamine**, **prazosin**): May negate the therapeutic effects of ephedrine
- **ANESTHETICS, GENERAL**: An increased risk of arrhythmias developing can occur if ephedrine is administered to patients who have received cyclopropane or a halogenated hydrocarbon anesthetic agent. Propranolol may be administered should these occur.
- **BETA-BLOCKERS**: Concomitant use of ephedrine with beta-blockers may diminish the effects of both drugs
- **DIGOXIN**: An increased risk of arrhythmias may occur if ephedrine is used concurrently with digitalis glycosides.
- **MONAMINE OXIDASE INHIBITORS** (including **amitraz**): Ephedrine should not be given within two weeks of a patient receiving monoamine oxidase inhibitors; severe hypertension, hyperpyrexia possible
- **SYMPATHOMIMETIC AGENTS, OTHER**: Ephedrine should not be administered with other sympathomimetic agents (e.g., **phenylpropa-nolamine**) as increased toxicity may result
- **RESERPINE**: May reverse the pressor effects of ephedrine
- **THEOPHYLLINE**: Ephedrine may increase the risk for theophylline toxicity
- **TRICYCLIC ANTIDEPRESSANTS**: May decrease the pressor effects of ephedrine
- **URINARY ALKALINIZERS** (e.g., **sodium bicarbonate**, **citrates**, **carbonic anhydrase inhibitors**): May reduce the urinary excretion of ephedrine and prolong its duration of activity. Dosage adjustments may be required to avoid toxic clinical signs.

Laboratory Considerations

- Beta-adrenergic agonists may decrease **serum potassium** concentrations. Clinical relevance is unknown.

Doses

■ DOGS:

For treatment of bronchospasm:

- a) For maintenance therapy: 1–2 mg/kg PO q8–12h (McKiernan 1992)
- b) 2 mg/kg PO q8–12h (Bonagura 1994)

For treatment of urinary incontinence responsive to adrenergic drugs:

- a) 5–15 mg (total dose) PO q8h (Labato 1994)
- b) 1.2 mg/kg PO q8h or 5–15 mg (total dose) PO q8h (Bartges 2003a)

For treatment of hypotension associated with anesthesia:

- a) 0.03–0.1 mg/kg IV bolus. Dilute 5 mg in 10 mL of saline and give the lower dosage first as sinus tachycardia may accompany the higher dose. May repeat in 5 minutes after first dose if hypotension does not improve. (Pablo 2003a)
- b) 0.1–0.25 mg/kg IV bolus (Mazzaferro 2005)
- c) 0.1 mg/kg IV; short (5–15 min) duration of action (Dodam 2005)

■ CATS:

For treatment of bronchospasm:

- a) For emergency treatment 2–5 mg PO (McKiernan 1992)

For treatment of urinary incontinence responsive to adrenergic drugs:

- a) 2–4 mg (total dose) PO q8h (Labato 1994)
- b) 2–4 mg/kg PO q6–12h or 2–4 mg (total dose) PO q8h (Bartges 2003a)
- c) 2–4 mg per cat PO q8–12h (Polzin 2005c)

Monitoring

- Clinical effectiveness
- Adverse effects (see above)

Client Information

- In order for this drug to be effective, it must be administered as directed by the veterinarian; missed doses will negate its effect. It may take several days for the full benefit of the drug to take place.
- Contact veterinarian if the animal demonstrates ongoing changes in behavior (restlessness, irritability) or if incontinence persists or increases.

Chemistry/Synonyms

A sympathomimetic alkaloid, ephedrine sulfate occurs as fine, odorless, white crystals or powder. Approximately 770 mg are soluble in one mL of water. The commercially available injection has a pH of 4.5–7.

Ephedrine sulfate may also be known as ephedrine sulphate.

Storage/Stability/Compatibility

Store ephedrine sulfate products in tight, light resistant containers at room temperature unless otherwise directed.

When used parenterally, ephedrine sulfate is usually administered directly and not diluted.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Ephedrine Sulfate Capsules: 25 mg; generic (West-Ward); (OTC)

Ephedrine Sulfate Injection: 50 mg/mL in 1 mL vials & preservative free in 1 mL amps; generic; (Rx)

In the USA, ephedrine sulfate is classified as a list 1 chemical (drugs that can be used as precursors to manufacture methamphetamine) and in some states it may be a controlled substance or have other restrictions placed upon its sale. Be alert to persons desiring to purchase this medication.

EPINEPHRINE

(ep-i-nef-rin) Adrenalin®

ALPHA- & BETA-ADRENERGIC AGONIST

Prescriber Highlights

- ▶ Alpha- & beta-adrenergic agonist agent used systemically for treating anaphylaxis & cardiac resuscitation
- ▶ Contraindications: Narrow-angle glaucoma, hypersensitivity to epinephrine, shock due to non-anaphylactoid causes, during general anesthesia with halogenated hydrocarbons, during labor (may delay the second stage), cardiac dilatation or coronary insufficiency; cases where vasopressor drugs are contraindicated (e.g., thyrotoxicosis, diabetes, hypertension, toxemia of pregnancy)
- ▶ Use extreme caution patients with a prefibrillatory cardiac rhythm
- ▶ Caution: Hypovolemia (not a substitute for adequate volume replacement)
- ▶ Do not inject with local anesthetics into small appendages of the body (e.g., toes, ears, etc.); may cause necrosis/sloughing
- ▶ Adverse Effects: Anxiety, tremor, excitability, vomiting, hypertension (overdosage), arrhythmias, hyperuricemia, & lactic acidosis (prolonged use or overdosage)
- ▶ Concentrations must not be confused
- ▶ Drug interactions

Uses/Indications

Epinephrine is employed primarily in veterinary medicine as a treatment for anaphylaxis or cardiac resuscitation. Because of its vasoconstrictive properties, epinephrine is added to local anesthetics to retard systemic absorption and prolong effect.

Pharmacology/Actions

Epinephrine is an endogenous adrenergic agent that has both alpha and beta activity. It relaxes smooth muscle in the bronchi and the iris, antagonizes the effects of histamine, increases glycogenolysis, and raises blood sugar. If given by rapid IV injection it causes direct stimulation of the heart (increased heart rate and contractility), and increases systolic blood pressure. If given slowly IV, it usually produces a modest rise in systolic pressure and a decrease in diastolic blood pressure. Total peripheral resistance is decreased because of beta effects.

Pharmacokinetics

Epinephrine is well-absorbed following IM or SC administration. IM injections are slightly faster absorbed than SC administration; absorption can be expedited by massaging the injection site. Epinephrine is rapidly metabolized in the GI tract and liver after oral administration and is not effective via this route. Following SC injection, the onset of action is generally within 5–10 minutes. The onset of action following IV administration is immediate and intensified.

Epinephrine does not cross the blood-brain barrier, but does cross the placenta and is distributed into milk.

Epinephrine's actions are ended primarily by the uptake and metabolism of the drug into sympathetic nerve endings. Metabolism takes place in both the liver and other tissues by monoamine oxidase (MAO) and catechol-O-methyltransferase (COMT) to inactive metabolites.

Contraindications/Precautions/Warnings

Epinephrine is contraindicated in patients with narrow-angle glaucoma, hypersensitivity to epinephrine, shock due to non-anaphylactoid causes, during general anesthesia with halogenated hydrocarbons or cyclopropane, during labor (may delay the second stage), and cardiac dilatation or coronary insufficiency. Epinephrine should also not be used in cases where vasopressor drugs are contraindicated (e.g., thyrotoxicosis, diabetes, hypertension, toxemia of pregnancy). It should not be injected with local anesthetics into small appendages of the body (e.g., toes, ears, etc.) because of the chance of necrosis and sloughing.

Use epinephrine with caution in cases of hypovolemia; it is not a substitute for adequate fluid replacement therapy. It should be used with extreme caution in patients with a prefibrillatory cardiac rhythm, because of its excitatory effects on the heart. While epinephrine's usefulness in asystole is well documented, it can cause ventricular fibrillation; use cautiously in cases of ventricular fibrillation.

Adverse Effects

Epinephrine can induce feelings of fear or anxiety, tremor, excitability, vomiting, hypertension (overdosage), arrhythmias (especially if patient has organic heart disease or has received another drug that sensitizes the heart to arrhythmias), hyperuricemia, and lactic acidosis (prolonged use or overdosage). Repeated injections can cause necrosis at the injection site.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known if this drug is excreted in milk.

Overdosage/Acute Toxicity

Clinical signs seen with overdosage or inadvertent IV administration of SC or IM dosages can include: sharp rises in systolic, diastolic, and venous blood pressures, cardiac arrhythmias, pulmonary edema and dyspnea, vomiting, headache, and chest pain. Cerebral hemorrhages may result because of the increased blood pressures. Renal failure, metabolic acidosis and cold skin may also result.

Because epinephrine has a relatively short duration of effect, treatment is mainly supportive. If necessary, the use of an alpha-adrenergic blocker (e.g., phentolamine) or a beta-adrenergic blocker (e.g., propranolol) can be considered to treat severe hypertension and cardiac arrhythmias. Prolonged periods of hypotension may follow, which may require treatment with norepinephrine.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving epinephrine and may be of significance in veterinary patients:

- **ALPHA-BLOCKERS** (e.g., **phentolamine**, **phenoxybenzamine**, **prazosin**): May negate the therapeutic effects of epinephrine
- **ANESTHETICS, GENERAL**: An increased risk of arrhythmias developing can occur if epinephrine is administered to patients who have received cyclopropane or a halogenated hydrocarbon anesthetic agent. Propofol may be administered should these occur.
- **ANTI-HISTAMINES**: Certain antihistamines (**diphenhydramine**, **chlorpheniramine**, etc.) may potentiate the effects of epinephrine
- **BETA-BLOCKERS**: Propranolol (or other beta-blockers) may potentiate hypertension, and antagonize epinephrine's cardiac and bronchodilating effects by blocking the beta effects of epinephrine
- **DIGOXIN**: An increased risk of arrhythmias may occur if epinephrine is used concurrently with digitalis glycosides
- **NITRATES**: May reverse the pressor effects of epinephrine
- **LEVOTHYROXINE**: May potentiate the effects of epinephrine
- **OXYTOCIC AGENTS**: Hypertension may result if epinephrine is used with oxytocic agents
- **SYMPATHOMIMETIC AGENTS, OTHER**: Epinephrine should not be administered with other sympathomimetic agents (e.g., **isoproterenol**) as increased toxicity may result
- **PHENOTHIAZINES**: May reverse the pressor effects of epinephrine
- **RESERPINE**: May potentiate the pressor effects of epinephrine
- **TRICYCLIC ANTIDEPRESSANTS**: May potentiate the effects of epinephrine

Doses

Note: Be certain when preparing injection that you do not confuse 1:1000 (1 mg/mL) with 1:10,000 (0.1 mg/mL) concentrations. To convert a 1:1000 solution to a 1:10,000 solution for IV or intratracheal use, dilute each mL with 9 mL of normal saline for injection. Epinephrine is only one aspect of treating cardiac arrest; refer to specialized references or protocols for more information.

■ DOGS:

Cardiac resuscitation (asystole):

- a) Both high dose (0.1–0.2 mg/kg) and low dose (0.01–0.02 mg/kg) IV or IO epinephrine have been advocated. In human medicine, generally the low dose is attempted first and if no response go to the high dose. In veterinary medicine (at present), either dose seems acceptable. Doses may be repeated at 3–5 minute intervals if there is no response. (Drobatz 2004)
- b) Although controversial, high dose epinephrine (0.2 mg/kg) is probably more effective than low dose (0.02 mg/kg) for cardiopulmonary cerebral resuscitation. It can be given every 3–5 minutes IV, preferably in a central vein. If venous access is not obtained, multiply the dose by 2–10 times and administer into the distal trachea with a syringe and a red rubber tube. (Proulx 2002)
- c) 0.01–0.1 mg/kg IV or IT q2–5 minutes (Rozanski 2002)

For anaphylaxis:

- a) 0.01–0.02 mg/kg IV; or the dosage may be doubled and given via the endotracheal tube if IV line is not yet established. In less severe cases, may be given IM or SC (Cohen 1995)
- b) 0.2–0.5 mg (total dose) SC or IM (Wohl 2005)
- c) For bronchoconstriction: 20 mcg/kg (0.02 mg/kg) IV, IM, SC, or IT (Johnson 2000)

For treatment of hypotension associated with anesthesia:

- a) 0.05–0.4 mcg/kg/min IV (Dodam 2005), (Mazzaferro 2005)

■ CATS:

For cardiac resuscitation: 0.05–0.5 mg (0.5–5 mL) of 1:10,000 solution intratracheally or intravenously. May need to repeat every 5 minutes. If intratracheal or IV sites are inaccessible, the intracardiac (IC) route may be used. IC dose is 0.5 to 5 micrograms/kg (0.0005 to 0.005 mg/kg). (Wingfield 1985)

For bronchoconstriction/anaphylaxis:

- a) 0.01–0.02 mg/kg IV; or the dosage may be doubled and given via the endotracheal tube if IV line is not yet established. In less severe cases, may be given IM or SC. (Cohen 1995)
- b) 20 mcg/kg (0.02 mg/kg) IV, IM, SC, or IT (Johnson 2000)

For feline asthma/anaphylaxis:

- a) 0.1 mL of a 1:1,000 dilution SC or IV (Noone 1986)
- b) Dilute 1 mL of 1:1,000 in 10 mL of saline and give 1 mL/10 kg body weight IV or IM. May repeat q5–15 minutes. (Kittleson 1985a)

■ BIRDS:

- a) 0.1 mg/kg IV or intracardiac (Harris 2003)

■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

For anaphylaxis:

- a) 3–5 mL of 1:1,000 per 450 kg of body weight either IM or SC; For foal resuscitation: 0.1 mL/kg of 1:1,000 IV (preferably diluted with saline) (Robinson 1987)

For cardiopulmonary resuscitation of newborn foals:

- a) 0.01–0.02 mg/kg (0.5–1 mL of a 1:1000 solution for a 50 kg foal) IV every 3 minutes until return of spontaneous circulation. If given intratracheally (IT), dose is 0.1–0.2 mL/kg. (Corley 2003)

■ RUMINANTS, SWINE:

For treatment of anaphylaxis:

- a) 0.5–1 mL/100 lbs. body weight of 1:1,000 SC or IM; dilute to 1:10,000 if using IV; may be repeated at 15 minute intervals. Often used in conjunction with corticosteroids and diphenhydramine (Clark 1986)

Monitoring

- Cardiac rate/rhythm
- Respiratory rate/auscultation during anaphylaxis
- Urine flow, if possible
- Blood pressure and blood gases, if indicated and possible

Client Information

- Pre-loaded syringes containing an appropriate amount of epinephrine may be dispensed to clients for treatment of anaphylaxis in animals with known hypersensitivity.
- Anaphylactic clinical signs (depending on species) should be discussed.
- Clients should be instructed in proper injection technique (IM or SC) and storage conditions for epinephrine.
- Do not use epinephrine if it is outdated, discolored, or contains a precipitate.

Chemistry/Synonyms

An endogenous catecholamine, epinephrine occurs as white to nearly white, microcrystalline powder or granules. It is only very slightly soluble in water, but it readily forms water-soluble salts (e.g., HCl) when combined with acids. Both the commercial products and endogenous epinephrine are in the Levo form, which is about 15 times more active than the dextro-isomer. The pH's of commercial injections are from 2.5–5.

Epinephrine is commonly called adrenalin.

Storage/Stability/Compatibility

Epinephrine HCl for injection should be stored in tight containers protected from light. Epinephrine will darken (oxidation) upon exposure to light and air. Do not use the injection if it is pink, brown, or contains a precipitate. The stability of the injection is dependent on the form and the preservatives present and may vary from one manufacturer to another. Epinephrine is rapidly destroyed by alkalis, or oxidizing agents.

Epinephrine HCl is reported to be physically **compatible** with the following intravenous solutions and drugs: Dextran 6% in dextrose 5%, Dextran 6% in normal saline, dextrose-Ringer's combinations, dextrose-lactated Ringer's combinations, dextrose-saline combinations, dextrose 2.5%, dextrose 5% (becomes unstable at a pH >5.5), dextrose 10%, Ringer's injection, lactated Ringer's injection, normal saline, and sodium lactate 1/6 M, amikacin sulfate, cimetidine HCl, dobutamine HCl, metaraminol bitartrate, and verapamil HCl.

Epinephrine HCl is reported to be physically **incompatible** with the following intravenous solutions and drugs: Ionosol-D-CM, Ionosol-PSL (Darrow's), Ionosol-T with dextrose 5% (**Note:** other Ionosol product are compatible), sodium chloride 5%, and sodium bicarbonate 5%, aminophylline, cephapirin sodium, hyaluronidase, mephentermine sulfate, sodium bicarbonate, and warfarin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Epinephrine HCl for Injection 1 mg/mL (1:1,000) in 1 mL amps and syringes and 10 mL, 30 mL and 100 mL vials; *Amtech® Epinephrine Injection USP* (Phoenix Scientific); *Am-Vet® Epinephrine 1:000* (Neogen); Epinephrine (Vedco, Vet Tek); *Epinject®* (Vetus); *Epinephrine 1:000* (AgriPharm, Durvet, Bimeda, Butler, Phoenix Pharmaceutical); Epinephrine Injection (AgriLabs); (Rx). Labeled for dogs, cats, cattle, horses, sheep and swine.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Epinephrine HCl for Injection: 1 mg/mL (1:1000) in 1 mL amps, 5 mL vials, 0.3 mL single dose auto-injectors; *Adrenalin Chloride®* (Monarch); *EpiPen®* (Dey); generic; (Abbott); (Rx)

Epinephrine HCl for Injection: 0.5 mg/mL (1:2000) in 0.3 mL single dose auto-injectors; *EpiPen Jr®* (Dey); (Rx)

Epinephrine HCl for Injection: 0.1 mg/mL (1:10,000) in 10 mL syringes & vials; generic; (Abbott); (Rx)

Epinephrine bitartrate is available as a powder form (aerosol) for inhalation, topical solution and a solution for nebulization; ophthalmic preparations are available.

EPOETIN ALFA ERYTHROPOIETIN

(eh-poe-ee-tin al-fah) EPO, rHuEPO, Epogen®, Procrit®

ERYTHROPOETIC AGENT

Prescriber Highlights

- ▶ Hormone that regulates erythropoiesis; used for anemia associated with chronic renal failure
- ▶ Contraindications: Patients with uncontrolled hypertension or in those who are hypersensitive to it
- ▶ Adverse Effects: Autoantibodies with resultant resistance to treatment, hypertension, seizures, iron depletion, local reactions at injection sites, fever, arthralgia, & mucocutaneous ulcers
- ▶ Adequate monitoring vital

Uses/Indications

EPO has been used to treat dogs and cats for anemia associated with chronic renal failure. Some clinicians state that because of the expense and potential risks associated with its use, PCV's should be in the "teens" before considering beginning EPO therapy. Development of antibodies to EPO has severely limited its clinical usefulness in veterinary medicine for chronic use. EPO may be demonstrated in the future to have significant benefits in reducing the number or volume of transfusions, or as a neuroprotective agent.

Pharmacology/Actions

Erythropoietin is a naturally occurring substance produced in the kidney and considered a hormone as it regulates erythropoiesis. It stimulates erythrocyte production by stimulating the differentiation and proliferation of committed red cell precursors. EPO also stimulates the release of reticulocytes.

Recombinant Human EPO alfa (r-HuEPO-alfa) serves as a substitute for endogenous EPO, primarily in patients with renal disease. Various uremic toxins may be responsible for the decreased production of EPO by the kidney.

Pharmacokinetics

EPO is only absorbed after parenteral administration. It is unclear whether the drug crosses the placenta or enters milk. The drug's metabolic fate is unknown. In patients with chronic renal failure, half-lives are prolonged approximately 20% over those with normal renal function. Depending on initial hematocrit and dose, correction of hematocrit may require 2–8 weeks.

Contraindications/Precautions/Warnings

EPO is contraindicated in patients with uncontrolled hypertension or in those who are hypersensitive to it (see Adverse Effects below). EPO cannot be recommended for use in equines. In animals with moderate to severe hypertension or iron deficiency, therapy should be started with caution or withheld until corrected.

Patients receiving EPO, generally require exogenous administration of iron supplements.

Adverse Effects

In dogs and cats, the most troublesome aspect of EPO therapy is the development of autoantibodies (20–70% incidence) with resultant resistance to further treatment. Perhaps up to 30% of all patients will develop antibodies significant enough to cause profound anemia,

arrestment of erythropoiesis, and transfusion dependency. Should a patient develop refractory anemia while receiving adequate EPO doses and have normal iron metabolism, a bone marrow aspirate should be considered. A myeloid:erythroid ratio of greater than 6 predicts significant autoantibody formation and contraindicates further EPO therapy. Some clinicians believe that the drug (EPO) should be withdrawn if PCV starts to drop while on therapy.

Other effects reported include: systemic hypertension, high blood viscosity, seizures, and iron depletion. Local reactions at injection sites (which may be a predictor of antibody formation), fever, arthralgia, and mucocutaneous ulcers are also possible. Other effects that have been noted that may be a result of the animal's disease (or compounded by such), include cardiac disease (may be related to hypertension associated with chronic renal failure). In humans, hyperkalemia, seizures, and iron deficiency have been reported.

Therapy should be discontinued if any of the following are recognized: polycythemia, fever, anorexia, joint pain, cellulitis, cutaneous or mucosal ulceration (Cowgill 2002).

Reproductive/Nursing Safety

Some teratogenic effects (decrease in body weight gain, delayed ossification, etc.) have been noted in pregnant rats given high dosages. Rabbits receiving 500 mg/kg during days 6–18 of gestation showed no untoward effects on offspring; however, use during pregnancy only when benefits outweigh the potential risks. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether epoetin alfa is excreted in milk, but it is unlikely to pose much risk to nursing offspring.

Overdosage/Acute Toxicity

Acute overdoses appear to be relatively free of adverse effects. Single doses of up to 1600 Units/kg in humans demonstrated no signs of toxicity. Chronic overdoses may lead to polycythemia or other adverse effects. Cautious phlebotomy may be employed should polycythemia occur.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving EPO and may be of significance in veterinary patients:

- **ANDROGENS:** May increase the sensitivity of erythroid progenitors; this interaction has been used for therapeutic effect; (**Note:** This effect has not been confirmed in well-controlled studies nor has the safety of this combination been determined.)
- **DESMOPRESSIN:** With EPO can decrease bleeding times
- **PROBENECID:** Probenecid has been demonstrated to reduce the renal tubular excretion of EPO; clinical significance remains unclear at this time

Laboratory Considerations

No laboratory interactions of major clinical importance have been described.

Doses

■ DOGS:

As adjunctive therapy for the treatment of anemia associated with end-stage renal disease:

- a) Initially, 100 Units/kg SC 3 times weekly, until the bottom of the target hematocrit range of 37–45% is attained. Once the lower range of the target hematocrit is attained, the dosing interval is changed to twice weekly. As the hematocrit ap-

proaches the upper target value, reduce to once weekly. The dosage schedule is then further modified as required and EPO administered between one and three times weekly to maintain hematocrit within the target range.

A lower initial dosage of 50–100 Units/kg 3 times weekly may be used if slower response is acceptable and appropriate for the patient. If adequate control is not achieved within 8–12 weeks, then dose can be increased by an additional 25–50 Units/kg every 3–4 weeks while maintaining dosing interval at 3 times a week. Withhold treatment temporarily if hematocrit exceeds target range. Once hematocrit is reestablished at the upper limit of the target range, re-institute treatment at a lower dosing schedule. Do not adjust dosage or dosing interval more often than once every three weeks (due to the long lag time for a response). Generally, a maintenance dose of 75–100 U/kg SC 1–2 times weekly is sufficient (not less than once per week, and not more than 3 times a week). Iron supplementation required. (Cowgill 2002)

- b) Initially, 48.4–145 units/kg SC three times a week. Most dogs and cats should be started at 97 units/kg SC 3 times a week. Use high end dose initially when anemia is severe (HCT less than 14%) and low end dose if hypertension is present or when anemia is not severe. Monitor hematocrit weekly until a target hematocrit of 37–45% is reached. When hematocrit reaches low end of target decrease dosing to two times weekly. Continue monitoring and adjusting dose and frequency as necessary, but take lag phase into account and do not adjust too rapidly. If animal requires >145 units/kg three times a week, evaluate for epoetin resistance. Oral iron supplements recommended for all patients on epoetin. (Polzin, Osborne et al. 2000)

■ CATS:

As adjunctive therapy for the treatment of anemia associated with end-stage renal disease:

- a) As above (for each specific author), but the target hematocrit is: 30–40%. (Cowgill 2002), (Polzin, Osborne et al. 2000)
- b) Consider using epoetin when PCV is <20%; dose at 75–100 U/kg SC three times a week until PCV is in the low normal range (35%), then reduce dose and frequency to 50–75 U/kg two times per week. Monitor PCV and blood pressure. It is important to administer iron at start of regime and until appetite is good. (Scherk 2003d)

■ FERRETS:

- a) 50–150 IU/kg IM 3 times weekly; may decrease to once weekly if RBC indices are significantly improved (Williams 2000)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: 50–150 IU/kg SC every 2–3 days until PVC is normal; then once weekly (q7 days) for at least 4 weeks (Ivey and Morrissey 2000)

Monitoring

- Hematocrit; PCV; (Initially weekly to every other week for 2–4 months, then when dose and Hct are stable, at 1–2 month intervals)
- Blood Pressure (initially, at least monthly then every 1–2 months thereafter)
- Renal Function Status
- Iron status (serum iron, TIBC), RBC indices (initially and regularly during therapy to insure adequate iron availability)

Client Information

- For outpatient administration, training in proper injection techniques, drug handling and storage should be performed

Chemistry/Synonyms

A biosynthetic form of the glycoprotein human hormone erythropoietin, epoetin alfa (EPO) has a molecular weight of approximately 30,000. It is commercially available as a sterile, preservative-free, colorless solution. Sodium chloride solution is added to adjust tonicity and is buffered with sodium citrate or citric acid. Human albumin (2.5 mg per vial) is also added to the solution.

Epoetins may also be known by the following synonyms and internationally registered trade names: erythropoietin, r-HuEPO, BI-71.052 (epoetin gamma), BM-06.019 (epoetin beta), EPO (epoetin alfa), EPOCH (epoetin beta), Bioyetin®, Culat®, Epogin®, Epomax®, Epopen®, Epotin®, Epoxitin®, Eprex®, Erantin®, Eritina®, Eritrogen®, Eritromax®, Erypo®, Espo®, Exetin-A®, Globuren®, Hemax®, Hemax-Eritron®, Hypercri®, Mepotin®, NeoRecormon®, Neorecormon®, Procrit®, Pronivel®, Recormon®, Repotin®, Tinax®, and Wepox®.

Storage/Stability/Compatibility

The injectable solution should be stored in the refrigerator (2–8°C); do not freeze. Do not shake the solution as denaturation of the protein with resultant loss of activity may occur. If light exposure is limited to 24 hours or less, no effects on potency should occur. When stored as directed, the solution has an expiration date of 2 years after manufacture. Do not mix with other drugs or use the same IV tubing with other drugs running. Because the solution contains no preservatives, the manufacturer recommends using each vial only as a single use.

A method of diluting the Amgen product to facilitate giving very small dosages has been described (Grodsky 1994). Using a 1:20 dilution (1 part *Epogen*® to 19 parts bacteriostatic normal saline does not require any additional albumin to prevent binding of the drug to container). No data is available commenting on this dilution's stability.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. It is also prohibited on the premises of a racing facility.

HUMAN-LABELED PRODUCTS:

Epoetin Alfa, Recombinant for Injection: 2000 units/mL, 3000 units/mL, 4000 units/mL, 10,000 units/mL, 20,000 units/mL and 40,000 units/mL in 1 mL and 2 mL (10,000U only) both single-dose and multidose vials; *Epogen*® (Amgen), *Procrit*® (Ortho Biotech); (Rx)

Uses/Indications

In cattle, eprinomectin is indicated for a variety of gastrointestinal roundworms including adult and L4 stages of *Haemonchus placei*, *Ostertagia ostertagi*, *Trichostrongylus axei* and *colubriformis*, *Cooperia oncophora/punctata/surnabada*, *Nematodirus helvetianus*, *Oesophagostomum radiatum*, *Bunostomum phlebotomum*, and *Trichuris* spp. (adults only); cattle grubs; lice; mange mites; horn flies (for 7 days after treatment), and lungworms (*Dictyocaulus viviparus*—for 21 days after treatment).

Topical eprinomectin may be useful for the topical treatment of ear mites (*Psoroptes cuniculi*) in rabbits. One small study (6 subjects) showed partial response when rabbits were dosed at 5 mg/kg topically, twice at 14 day intervals. (Ulutas, Voyvoda et al. 2005)

Pharmacology/Actions

Eprinomectin binds selectively to glutamate-gated chloride ion channels that occur in invertebrate nerve and muscle cells. This leads to an increase in cell membrane permeability to chloride ions, leading to paralysis and death of the parasite. Like ivermectin, eprinomectin enhances the release of gamma amino butyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks the post-synaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. These compounds are generally not toxic to mammals as they do not have glutamate-gated chloride channels and do not readily cross the blood-brain barrier.

Pharmacokinetics

No information noted.

Contraindications/Precautions/Warnings

Do not give orally or intravenously.

Adverse Effects

At the time of review, no adverse reactions have been reported.

Overdosage/Acute Toxicity

Calves given up to 5X dosage showed no signs of adverse effects. One subject (of 6) showed signs of mydriasis when given a 10X dose.

Drug Interactions

No interactions noted

Doses

■ CATTLE:

For labeled indications:

- 1 mL per 10 kg (22 lb) body weight applied topically along backline in a narrow strip from the withers to the tailhead (Package Insert; *Ivomec*® *Eprinex*®—Merial)

Client Information

- When used as labeled, there are no milk or meat withdrawal times required.
- Weather conditions (including rainfall) during administration do not affect efficacy.
- Do not apply to backline if covered with mud or manure.
- Dispose of containers in an approved landfill or by incineration; do not contaminate water as eprinomectin may adversely affect fish and aquatic organisms.

Chemistry/Synonyms

A member of the avermectin-class of antiparasitic agents, eprinomectin is also known as MK-397 or 4-epi-acetyl-amino-4-deoxy-avermectin B1.

EPRINOMECTIN

(e-pri-no-mek-tin) Ivomec® Eprinex®

TOPICAL AVERMECTIN ANTIPARASITIC AGENT

Prescriber Highlights

- ▶ Topically applied avermectin antiparasiticide for cattle
- ▶ Used as labeled; there are no milk or meat withdrawal times required

Storage/Stability

The commercially available product should be stored protected from light and kept at 86°F (30°C) or less. Storage up to 104°F (40°C) is permitted for a short period.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Eprinomectin Topical (Pour-On) Solution: 5 mg/mL in 250 mL/8.5 fl oz and 1 L/33.8 fl oz bottle with a squeeze-measure-pour-system, or a 2.5 L/84.5 fl oz and 5 L/169 fl oz collapsible pack for use with appropriate automatic dosing equipment; *Ivomec® Eprinex®* (Merial); (OTC). Approved for use in beef or dairy cattle.

HUMAN-LABELED PRODUCTS: None

Epsom Salts — see Magnesium Sulfate

EPSIPRANTEL

(ep-si-pran-tel) Cestex®

CESTOCIDAL ANTIPARASITIC AGENT

Prescriber Highlights

- Oral cestocide for dogs & cats
- Not appreciably absorbed when given orally
- Not approved in puppies or kittens less than 7 weeks old
- Adverse Effects: GI (vomiting, diarrhea) possible

Uses/Indications

Epsiprantel is indicated for the treatment (removal) of *Dipylidium caninum* and *Taenia pisiformis* in dogs, and *Dipylidium caninum* and *Taenia taeniaeformis* in cats.

Pharmacology/Actions

Epsiprantel's exact mechanism of action against cestodes has not been determined. The tapeworm's ability to regulate calcium is apparently affected, causing tetany and disruption of attachment to the host. Alteration to the integument makes the worm vulnerable to digestion by the host animal.

Pharmacokinetics

Unlike praziquantel, epsiprantel is absorbed very poorly after oral administration and the bulk of the drug is eliminated in the feces. Less than 0.1% of the drug is recovered in the urine after dosing. No metabolites have thus far been detected.

Contraindications/Precautions/Warnings

There are no labeled contraindications to this drug, but the manufacturer states not to use it in puppies or kittens less than 7 weeks of age.

Adverse Effects

Adverse effects would be unexpected with this agent, although vomiting and/or diarrhea could potentially occur.

Reproductive/Nursing Safety

Safety for use in pregnant or breeding animals has not been determined, but teratogenic effects would be highly unlikely since the drug is so poorly absorbed.

Overdosage/Acute Toxicity

Acute toxicity resulting from an inadvertent overdose is highly unlikely. Doses as high as 36X the recommended dose resulted in vomiting in some of the kittens tested. Single doses of 36X those recommended in dogs caused no adverse effects.

Drug Interactions/Laboratory Considerations

None reported; theoretically, prokinetic agents or fast acting laxatives may reduce the drug's efficacy

Doses**■ DOGS:**

- a) 5.5 mg/kg (2.5 mg/lb) PO once; round up to the next larger tablet size (Package insert; *Cestex®*—Pfizer)

■ CATS:

- a) 2.75 mg/kg PO once. Cats up to 10 lb. should receive one 12.5 mg tablet; cats 11–20 lb. should receive one 25 mg tablet (Package insert; *Cestex®*—Pfizer)

Monitoring

- Clinical efficacy

Client Information

- Fasting is not required nor is it recommended before dosing
- Because the worm may be partially or completely digested, worm fragments may not be seen in the feces after treatment.
- A single dose is usually effective, but measures should be taken to prevent reinfection, particularly against *D. caninum*.

Chemistry/Synonyms

A pyrazino-benzazepine oral cesticide, epsiprantel occurs as a white powder that is sparingly soluble in water.

Epsiprantel may also be known as BRL-38705 or *Cestex®*.

Storage/Stability

Tablets should be stored at room temperature.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Epsiprantel Oral Tablets (Film-coated): 12.5, 25, 50 & 100 mg; *Cestex®* (Pfizer); (Rx). Approved for use in dogs and cats.

HUMAN-APPROVED PRODUCTS: None

ERGOCALCIFEROL

(er-goh-kal-sif-er-ole) Vitamin D2, Calciferol, Drisdol®

VITAMIN D ANALOG

Prescriber Highlights

- May be used to treat hypocalcemia associated with hypoparathyroidism, but DHT or calcitriol usually recommended first
- Less expensive than DHT or calcitriol, but takes large initial doses for effect, effects take longer to be seen, & if hypercalcemia develops, takes longer (up to 18 weeks) for toxicity relief

Uses/Indications

Ergocalciferol is sometimes used in dogs or cats to treat hypocalcemia secondary to parathyroid gland failure, particularly when dihydrotachysterol or calcitriol are too expensive for the owner. When compared to those agents, ergocalciferol takes longer to have a maximal effect on serum calcium. Additionally, if hypercalcemia should develop, ergocalciferol's effects persist longer than either calcitriol or dihydrotachysterol.

Pharmacology/Actions

Ergocalciferol is first hydroxylated in the liver to 25-hydroxyvitamin D (has some activity) and then activated in the kidneys to 1,25-dihydroxyvitamin D, the primary active form of the drug. Vitamin D is considered a hormone and, in conjunction with parathormone (PTH) and calcitonin, regulates calcium homeostasis in the body. Active analogues (or metabolites) of vitamin D enhance calcium and phosphate absorption from the GI tract, promote reabsorption of calcium by the renal tubules, and increase the rate of accretion and resorption of minerals in bone.

Pharmacokinetics

Specific pharmacokinetic values for dogs and cats were not located. But the following information (human-based) generally applies: In the presence of bile salts, ergocalciferol is absorbed from the small intestine; after conversion to its 25-hydroxylated form in the liver and kidneys, it is stored in the liver and fat. Cats do not appear to convert ergocalciferol to its 25-hydroxylate form as well as cholecalciferol. Several days of therapy may be required until distribution steady state is achieved. In dogs and cats, maximal effect on calcium homeostasis is usually noted from 5–21 days after treatment was begun; effects may persist for up to 18 weeks once treatment is discontinued (Feldman 2005a).

Contraindications/Precautions/Warnings

Ergocalciferol, at therapeutic dosages, is contraindicated in patients with hypercalcemia, vitamin D toxicity, malabsorption syndrome, or abnormal sensitivity to the effects of vitamin D. It should be used with extreme caution in patients with hyperphosphatemia. As patients with kidney dysfunction may not convert ergocalciferol into the primary active metabolite, calcitriol or DHT would be preferred since they do not require activation by the kidney. Chronic therapy should not be initiated unless owners are willing to commit to ongoing patient monitoring.

Adverse Effects

The primary concern with using ergocalciferol is “overshooting” the dosage with resultant hypercalcemia and, potentially, hyperphosphatemia or nephrocalcinosis. Hypercalcemia can persist for weeks to months.

Reproductive/Nursing Safety

Hypervitaminosis D in pregnant females has been implicated in causing teratogenic effects in animals and infants. Potential benefits of therapy must be weighed against the risks if considering use in pregnant dogs or cats.

As large doses of vitamin D can be excreted into milk, consider using milk replacer in offspring of dams receiving therapeutic dosages of ergocalciferol.

Overdosage/Acute Toxicity

Because of the potential serious ramifications of overdoses, contacting an animal poison control center is strongly recommended. The toxic acute oral dose of ergocalciferol in dogs is reported as 4 mg/kg (160,000 units/kg).

Acute ingestions should be managed using established protocols for removal or prevention of the drug being absorbed from the GI. Orally administered mineral oil may reduce absorption and enhance fecal elimination.

Hypercalcemia secondary to chronic dosing of the drug should be treated by first temporarily discontinuing it and exogenous calcium therapy. If the hypercalcemia is severe, furosemide, calcium-free IV fluids (e.g., normal saline), urine acidification, and corticosteroids may be employed. Because of the long duration of action of ergocalciferol (potentially up to 18 weeks), hypercalcemia may persist. Restart therapy (if desired) at a reduced dosage only when calcium serum levels return to the normal range. Diligent monitoring is required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ergocalciferol and may be of significance in veterinary patients:

- **CORTICOSTEROIDS:** Can reduce the effects of vitamin D analogs
- **DIGOXIN or VERAPAMIL:** Patients on these drugs are sensitive to the effects of hypercalcemia; intensified monitoring is required
- **MINERAL OIL:** May reduce the amount of ergocalciferol absorbed
- **THIAZIDE DIURETICS:** May cause hypercalcemia when given in conjunction with Vitamin D analogs

Laboratory Considerations

- **Serum cholesterol** levels may be falsely elevated by vitamin D analogs when using the Zlatkis-Zak reaction for determination.

Doses

■ DOGS/CATS:

For maintenance therapy of parathyroid failure after using parenteral calcium to control hypocalcemic tetany:

- a) Dihydrotachysterol or calcitriol are preferred, but ergocalciferol is less expensive. If using ergocalciferol, patient should be hospitalized. Initially give ergocalciferol at 4000–6000 units/kg PO once daily. After 1–5 days, parenteral calcium can usually be discontinued. Patient should remain hospitalized until serum calcium concentration remains between 8–10 mg/dL without parenteral calcium support, then patient can be discharged. Continue ergocalciferol, but administer every other day. Weekly serum calcium concentrations should be performed and ergocalciferol dosage adjusted to maintain serum calcium concentrations between 8–9.5 mg/dL. Maintenance doses usually range from 1000–2000 units/kg PO once daily to once weekly. Goal is to prevent hypocalcemic tetany, but not induce hypercalcemia. Once animal is stable, monthly rechecks for 6 months are strongly advised; then every 2–3 months thereafter. (Feldman 2005a)

Monitoring

- See dosage information above

Client Information

- While ergocalciferol is less expensive than DHT or calcitriol, it is usually not recommended as it takes longer to have an effect and can persist in the body longer than DHT or calcitriol
- Using vitamin D products may require lifelong treatment and regular laboratory monitoring
- While this agent can treat low calcium, it can cause calcium levels in the blood to become too high; this effect can last for many weeks, even after the medication is discontinued

Chemistry/Synonyms

Ergocalciferol is obtained by irradiating (with ultraviolet light) ergosterol, a sterol present in fungi and yeasts. It occurs as white or almost white crystals or yellowish crystalline powder and is practically insoluble in water, but is soluble in fatty oils. One mg of ergocalciferol provides 40,000 units of vitamin D activity.

Ergocalciferol may be known as calciferol, vitamin D₂, viosterol, activated ergosterol, or irradiated ergosterol; there are many international trade names.

Storage/Stability

Ergosterol is sensitive to light, heat and air. Store capsules or liquid at room temperature (15–30°C) and protect from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ergocalciferol Oral Liquid (Drops): 8,000 units/mL (200 mcg/mL) in 60 mL btl; *Drisdol*® Drops (Sanofi), *Calciferol*® Drops (Schwarz); (OTC)

Ergocalciferol Capsules: 50,000 units (1.25 mg); *Drisdol*® (Sanofi), Vitamin D (Pliva); (Rx)

ERTAPENEM SODIUM

(er-ta-pen-um) Invanz®

CARBAPENEM ANTIBIOTIC**Prescriber Highlights**

- ▶ Carbapenem antibiotic similar to imipenem & meropenem, but has narrower spectrum of activity
- ▶ Not effective against *Pseudomonas* or *Acinetobacter*
- ▶ May only need to be dosed once daily
- ▶ Very limited information available for use in dogs or cats; must be considered investigational

Uses/Indications

Ertapenem may be useful in treating resistant gram-negative bacterial infections, particularly when aminoglycoside use would be risky (*i.e.*, renal failure) or not effective (*i.e.*, resistance or CNS infections), and when meropenem is not available. While ertapenem has a broad spectrum, it is not active against *Pseudomonas aeruginosa*. It potentially could be useful against mixed anaerobic/gram-negative aerobic infections when *Pseudomonas* is not considered a likely pathogen.

Pharmacology/Actions

Ertapenem is a carbapenem antibiotic similar to imipenem and meropenem. Like other beta-lactams, it inhibits bacterial cell wall synthesis and is usually bactericidal.

Ertapenem has a broad antibacterial spectrum similar to that of imipenem, but it is more active against *Enterobacteriaceae* and anaerobes, has equivalent activity against gram-positive bacteria, and minimal activity against *Pseudomonas aeruginosa* and *Acinetobacter*. Methicillin-resistant *Staphylococci* and *Enterococcus* are usually resistant to ertapenem. Because ertapenem, like meropenem, is more stable than imipenem to renal dehydropeptidase I, it does not require the addition of cilastatin to inhibit that enzyme.

Pharmacokinetics

At the time of writing, no pharmacokinetic data was available for dogs or cats.

In humans, the drug must be administered parenterally as it is not appreciably absorbed after oral administration. Intramuscular bioavailability is about 90% and peak plasma levels occur in approximately 2.3 hours. Ertapenem exhibits concentration-dependent binding to human plasma proteins. At plasma concentrations of <100 mcg/mL it is 95% bound; at 300 mcg/mL, 85% bound. Ertapenem biotransformation is not dependent on hepatic mechanisms as the major metabolite (inactive) is formed by hydrolysis of the beta-lactam ring. Approximately 80% of an IV dose is excreted in the urine, evenly split between inactive metabolites and unchanged drug. Approximately 10% is excreted in the feces. In young, healthy adults, elimination half-life is about 4 hours; about 2.5 hours in pediatric patients.

Contraindications/Precautions/Warnings

Ertapenem is contraindicated in patients hypersensitive to it or other carbapenems and those that have developed anaphylaxis after receiving any beta-lactam antibiotic. It is contraindicated in patients hypersensitive to lidocaine or other amide-type local anesthetics (if used IM with 1% lidocaine as the diluent).

As ertapenem has not been widely used clinically in veterinary medicine and little information for use in dogs or cats is published, consider its use investigational.

Adverse Effects

The adverse effect profile for ertapenem in dogs or cats is unknown. In humans, intravenous injection site reactions are the most common adverse reaction. Gastrointestinal effects (nausea, vomiting, diarrhea), headache, or tachycardia have occasionally been reported. Rarely, hypersensitivity or CNS effects (hallucinations, agitation, seizures, etc.) have been seen.

Reproductive/Nursing Safety

Ertapenem has been shown to cross the placenta in rats, but no teratogenic effects have been reported. In humans, ertapenem is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Although risk cannot be ruled out, it is likely that ertapenem is safe to use while nursing.

Overdosage/Acute Toxicity

Inadvertent overdoses are unlikely. Humans receiving 3 grams intravenously had an increased incidence of nausea and diarrhea. Should an overdose occur and adverse effects noted, treat supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ertapenem and may be of significance in veterinary patients:

- **PROBENECID:** In humans, coadministration of ertapenem with probenecid can increase ertapenem AUC by 25% and elimination half-life by about 20%. Because of these relatively small effects, the manufacturer does not recommend using probenecid to extend the half-life of ertapenem.

Laboratory Considerations

No specific laboratory interactions or concerns were noted.

Doses

■ DOGS / CATS:

Note: There is very little information available regarding ertapenem use in dogs or cats and, therefore use must be considered investigational. If the drug is to be administered, it is suggested to use the human pediatric dose of 15 mg/kg IV or IM every 12 hours (not to exceed a daily dosage of 1 gram). Monitor the literature for additional data and recommendations.

Monitoring

- Clinical efficacy (WBC, fever, etc.)
- Adverse effects (potentially: GI, neurotoxicity, hypersensitivity); in humans receiving ertapenem for a prolonged period, hepatic, hematopoietic, and renal function are suggested for periodic assessment

Client Information

- Clients should understand the investigational nature of using this drug in animals and that it should be administered only by veterinary professionals

Chemistry/Synonyms

Ertapenem sodium is a synthetic 1-(beta) methyl carbapenem antibiotic that occurs as a white to off-white, hygroscopic, crystalline powder. It is soluble in water and normal saline.

Ertapenem may also be known as L-749345, ML-0826, ZD-4433, ertapenemum or *Invanz*®.

Storage/Stability/Compatibility

The 1 gram injectable product contains approximately 6 mEq of sodium and 175 mg of sodium bicarbonate (as an excipient). It should be stored at temperatures at, or below, 25°C.

For intravenous use, vial contents can be reconstituted with 10 mL of water for injection, bacteriostatic water for injection, or 0.9% sodium chloride injection. After shaking to dissolve the powder, immediately transfer to a 50 mL bag of 0.9% sodium chloride. Do not use diluents containing dextrose. Once reconstituted and diluted in normal saline for IV use, ertapenem is stable at room temperature for 6 hours. If refrigerated, it can be stored for 24 hours and used within 4 hours after removal from the refrigerator. Do not freeze reconstituted solutions.

If ertapenem is to be given IM, dilute the vial with 3.2 mL of 1% lidocaine HCl injection (*without epinephrine*). Use within one hour. Do not give IV.

Do not mix ertapenem with other medications or use IV solutions containing dextrose.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ertapenem Sodium Powder for Injection: 1 g (as ertapenem) vials; *Invanz*® (Merck); (Rx)

ERYTHROMYCIN ERYTHROMYCIN ESTOLATE ERYTHROMYCIN ETHYLSUCCINATE ERYTHROMYCIN LACTOBIONATE

(er-ith-roe-mye-sin) Gallimycin®

MACROLIDE ANTIBIOTIC

Prescriber Highlights

- ▶ Macrolide antibiotic; also used as a prokinetic agent
- ▶ Contraindicated in rabbits, gerbils, guinea pigs, & hamsters; oral use in ruminants, adult horses(?), hypersensitivity
- ▶ Adverse Effects: GI distress (oral), pain on IM injection; thrombophlebitis (IV), hyperthermia (foals)
- ▶ Many drug interactions possible

Uses/Indications

Erythromycin is approved for use to treat infections caused by susceptible organisms in swine, sheep, and cattle. It is often employed when an animal is hypersensitive to penicillins or if other antibiotics are ineffective against a certain organism.

Erythromycin, at present, is considered to be one of the treatments of choice (with rifampin) for the treatment of *C. (Rhodococcus) equi* infections in foals. Erythromycin estolate and microencapsulated base appear to be the most efficacious forms of the drug in foals due to better absorption and less frequent adverse effects.

Erythromycin may be used as a prokinetic agent to increase gastric emptying in dogs and cats. It may also be beneficial in treating reflux esophagitis.

Pharmacology/Actions

Erythromycin is usually a bacteriostatic agent, but in high concentrations or against highly susceptible organisms it may be bactericidal. The macrolides (erythromycin and tylosin) are believed to act by binding to the 50S ribosomal subunit of susceptible bacteria, thereby inhibiting peptide bond formation.

Erythromycin has *in vitro* activity against gram-positive cocci (staphylococci, streptococci), gram-positive bacilli, (*Bacillus anthracis*, *Corynebacterium*, *Clostridium* spp., (not *C. difficile*), *Listeria*, *Erysipelothrix*), and some strains of gram-negative bacilli, including *Haemophilus*, *Pasturella*, and *Brucella*. Some strains of *Actinomyces*, *Mycoplasma*, *Chlamydia*, *Ureaplasma*, and *Rickettsia* are also inhibited by erythromycin. Most strains of the family Enterobacteriaceae (*Pseudomonas*, *E. coli*, *Klebsiella*, etc.) are resistant to erythromycin.

Erythromycin is less active at low pHs and many clinicians suggest alkalinizing the urine if using the drug to treat UTIs.

At sub-antimicrobial doses, erythromycin mimics the effects of motilin (cats, humans, rabbits) or 5-hydroxytryptophan₃ (5-HT₃) and stimulates migrating motility complexes and antegrade peristalsis. By inducing antral contractions, gastric emptying is enhanced. Erythromycin also increases lower esophageal pressure. Erythromycin's prokinetic mechanism of action in dogs is not completely understood, but probably is via activation of 5-HT₃ receptors.

Pharmacokinetics

Erythromycin is absorbed after oral administration in the upper small intestine. Several factors can influence the bioavailability of erythromycin, including salt form, dosage form, GI acidity, food in the stomach, and stomach emptying time. Both erythromycin base and stearate are susceptible to acid degradation; enteric coatings are often used to alleviate this. Both the ethylsuccinate and estolate forms are dissociated in the upper small intestine and then absorbed. After IM or SC injection of the polyethylene-based veterinary product (*Erythro*[®]-200; *Gallimycin*[®]-200) in cattle, absorption is very slow. Bioavailabilities are only about 40% after SC injection and 65% after IM injection.

Erythromycin is distributed throughout the body into most fluids and tissues including the prostate, macrophages, and leukocytes. CSF levels are poor. In foals, erythromycin levels in bronchiolar lavage cells are equivalent to those found in the serum, but concentrations in pulmonary epithelial lining fluid are lower. Erythromycin may be 73–81% bound to serum proteins and the estolate salt, 96% bound. Erythromycin will cross the placenta; fetal serum levels are 5–20% of maternal levels. Erythromycin levels of about 50% of those found in the serum can be detected in milk. The volume of distribution for erythromycin in dogs is reportedly 2 L/kg; 3.7–7.2 L/kg in foals; 2.3 L/kg in mares; and 0.8–1.6 L/kg in cattle. In lactating dairy cattle, the milk to plasma ratio about 6–7.

Erythromycin is primarily excreted unchanged in the bile, but is also partly metabolized by the liver via N-demethylation to inactive metabolites. Some of the drug is reabsorbed after biliary excretion. Only about 2–5% of a dose is excreted unchanged in the urine.

The reported elimination half-life of erythromycin in various species is: 60–90 minutes in dogs and cats, 60–70 minutes in foals and mares, and 190 minutes in cattle.

Contraindications/Precautions/Warnings

Erythromycin is contraindicated in patients hypersensitive to it. In humans, the estolate form has been associated rarely with the development of cholestatic hepatitis. This effect has not apparently been reported in veterinary species, but the estolate should probably be avoided in patients with preexisting liver dysfunction.

As it may induce a toxic enterocolitis, erythromycin (and other macrolides) is contraindicated in rabbits, gerbils, guinea pigs, and hamsters.

Many clinicians believe that erythromycin is contraindicated in adult horses (see Adverse Effects below), and oral erythromycin should not be used in ruminants as severe diarrhea may result.

Adverse Effects

Adverse effects are relatively infrequent with erythromycin when used in small animals, swine, sheep, or cattle. When injected IM, local reactions and pain at the injection site may occur. Oral erythromycin may occasionally cause GI disturbances such as diarrhea, anorexia, and vomiting. Rectal edema and partial anal prolapse have been associated with erythromycin in swine. Intravenous injections must be given very slowly, as they can readily cause thrombophlebitis. Allergic reactions can occur but are thought to be rare.

Oral erythromycin should not be used in ruminants as severe diarrheas may result.

In foals treated with erythromycin, a mild, self-limiting diarrhea can occur; however, severe enterocolitis is possible. Erythromycin may alter temperature homeostasis in foals. Foals between the ages of 2–4 months old have been reported to develop hyperthermia with associated respiratory distress and tachypnea. Physically cooling off these animals has been successful in controlling this effect.

Adult horses may develop severe, sometimes fatal, diarrhea as from erythromycin making the use of the drug in adults very controversial.

When used as prokinetic agent, erythromycin may actually increase clinical signs of intestinal distress as it can stimulate emptying of larger food particles into the intestine than is normal.

Reproductive/Nursing Safety

While erythromycin has not demonstrated teratogenic effects in rats, and the drug is not thought to possess serious teratogenic potential, it should only be used during pregnancy when the benefits outweigh the risks. In humans, the FDA categorizes erythromycin and its salts, except ethylsuccinate, as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

In humans, the FDA categorizes erythromycin ethylsuccinate as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Erythromycin is excreted in milk and may concentrate (observed milk:plasma ratio of 0.5). Erythromycin is considered compatible with breastfeeding by the American Academy of Pediatrics.

Overdosage/Acute Toxicity

With the exception of the adverse effects outlined above, erythromycin is relatively non-toxic; however, shock reactions have been reported in baby pigs receiving erythromycin overdoses.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving erythromycin and may be of significance in veterinary patients:

- **AZOLE ANTIFUNGALS (ketoconazole, fluconazole, itraconazole):** Possible increased erythromycin levels
- **CISAPRIDE:** Erythromycin can inhibit the metabolism of cisapride and the manufacturer states that use of these drugs together (in humans) is contraindicated
- **CHLORAMPHENICOL:** *in vitro* evidence of antagonism
- **CLINDAMYCIN, LINCOMYCIN:** *in vitro* evidence of antagonism
- **DIGOXIN:** Erythromycin may increase the serum level of digoxin
- **DILTIAZEM, VERAPAMIL:** May increase erythromycin levels
- **ERGOT ALKALOIDS:** Acute ergot toxicity possible
- **OMEPRAZOLE:** Erythromycin and omeprazole can increase the plasma levels of one another
- **WARFARIN:** Erythromycin may potentiate the effects of oral anti-coagulant drugs

Erythromycin can inhibit the metabolism of other drugs that use the CYP3A subfamily of the cytochrome P450 enzyme system. Depending on the therapeutic index of the drug(s) involved, therapeutic drug monitoring and/or dosage reduction may be required if the drugs must be used together. These drugs include:

- **ALFENTANIL**
- **BROMOCRIPTINE**
- **BUSPIRONE**

- **CARBAMAZEPINE**
- **CYCLOSPORINE**
- **DISOPYRAMIDE** (also risk of increased QT interval)
- **METHYLPREDNISOLONE**
- **MIDAZOLAM, ALPRAZOLAM, TRIAZOLAM**
- **QUINIDINE** (also risk of increased QT interval)
- **SILDENAFIL**
- **TACROLIMUS** (systemic)
- **THEOPHYLLINE**

Laboratory Considerations

- Erythromycin may cause falsely elevated values of **AST** (SGOT), and **ALT** (SGPT) when using colorimetric assays.
- Fluorometric determinations of **urinary catecholamines** can be altered by concomitant erythromycin administration.

Doses

■ DOGS:

For susceptible infections:

- a) 10–20 mg/kg PO three times daily (Aucoin 2000)
- b) For localized, soft tissue infections: 10–15 mg/kg PO q8h or 15–25 mg/kg PO q12h for 7–10 days;
For systemic, bacteremia infections: 22 mg/kg PO or IV q8h for as long as necessary (Greene and Watson 1998)

As a prokinetic agent:

- a) 0.5–1 mg/kg PO q8h (Hall and Washabau 2000)

■ CATS:

For susceptible infections:

- a) 10–20 mg/kg PO three times daily (Aucoin 2000)
- b) For localized, soft tissue infections: 10–15 mg/kg PO q8h or 15–25 mg/kg PO q12h for 7–10 days;
For systemic, bacteremia infections: 22 mg/kg PO or IV q8h for as long as necessary (Greene and Watson 1998)

As a prokinetic agent:

- a) 0.5–1 mg/kg PO q8h (Hall and Washabau 2000)

■ FERRETS:

For susceptible infections:

- a) 10 mg/kg PO 4 times daily (Williams 2000)

■ BIRDS:

For susceptible infections:

- a) Oral suspension: 60 mg/kg PO q12h (Hoeffer 1995)
- b) Ratites: 5–10 mg/kg PO 3 times daily (Jenson 1998)

■ CATTLE:

For susceptible infections:

- a) 4–8 mg/kg IM q12–24h (Jenkins 1987b)
- b) For bronchopneumonia and fibrinous pneumonia in cattle associated with bacteria sensitive to erythromycin and resistant to sulfas, penicillin G and tetracyclines: Using *Erythro-200*[®]: 44 mg/kg IM q24h usually for a maximum of 4 days. Inject no more than 10 mL at any one site. Do not inject at any site previously used. Severe local tissue reactions may occur. Recommend a 30-day slaughter withdrawal at this dosage. (Hjerpe 1986)

For mastitis:

- a) Dry cow (using dry cow formula): Milk out affected quarter, clean and disinfect. Infuse contents of one syringe into each affected quarter at time of drying off. Close teat orifice with gentle pressure and massage udder.
- b) Lactating cow (using lactating cow formula): As above, but repeat after each milking for 3 milkings (Label directions; *Erythro*[®]-Dry and *Erythro*[®]-36—Ceva)

■ HORSES:

For treatment of *C. (Rhodococcus) equi* infections in foals:

- a) Erythromycin: 15–25 mg/kg PO q12–24h daily, with Rifampin (5 mg/kg, PO q12h). Treatment may be necessary for 1–3 months. (Chaffin 2006b)
- b) Erythromycin: 25 mg/kg PO q12h with rifampin: 3–5 mg/kg PO q12h. If rifampin use becomes cost prohibitive, use erythromycin alone. Treat for 4–6 weeks or until lungs are clear of abscesses on radiographs. (Foreman 1999)

For treatment of proliferative enteropathy caused by *L. intracellularis* infections in foals:

- a) Erythromycin estolate: 25 mg/kg PO q6–8h, with rifampin: 10 mg/kg PO q12h for a minimum of 21 days (Lavoie and Drolet 2003)

For susceptible infections:

- a) Foals: Erythromycin estolate: 25 mg/kg PO q6h; Erythromycin gluceptate: 5 mg/kg IV q4–6h (Caprile and Short 1987); (Brumbaugh 1999)

As a prokinetic agent:

- a) 0.1–1 mg/kg, IV or erythromycin lactobionate 2.2 mg/kg IV over a 30–60 minute period every 6 hours. Dose in a 450 kg horse is 1 gram. (Moore 1999)

■ SWINE:

For susceptible infections:

- a) For respiratory infections: 2.2–6.6 mg/kg IM once daily
- b) For scours in young pigs: 22 mg/kg IM in one or more daily doses (Label directions; *Erythro*[®]-100 and *Erythro*[®]-200—Ceva)

■ SHEEP:

For susceptible infections:

- a) For respiratory infections in older animals: 2.2 mg/kg IM once daily as indicated.
- b) For prevention of “dysentery” in newborn lambs when the likely causative agent is susceptible to erythromycin: 123 mg/kg IM once soon after birth (Label directions; *Erythro*[®]-100 and *Erythro*[®]-200—Ceva)

Monitoring

- Clinical efficacy
- Adverse effects (periodic liver function tests if patient receiving erythromycin estolate long-term; may not be necessary for foals receiving erythromycin and rifampin for *Rhodococcus* infections)

Client Information

- The intramuscular 100 mg/mL (*Erythro-100*[®]) product (*Erythro-200*[®]) has quite specific instructions on where and how to inject the drug. Refer to the label directions or package insert for more information before using.
- When administering orally to small animals, give on an empty stomach unless gastrointestinal signs (vomiting, lack of appetite, diarrhea) occur, then give with food. The estolate, ethylsuccinate or enteric-coated forms of erythromycin may be given with or without food.
- If gastrointestinal adverse effects are severe or persist, contact veterinarian.

Chemistry/Synonyms

A macrolide antibiotic, produced from *Streptomyces erythreus*, erythromycin is a weak base that is available commercially in several salts and esters. It has a pK_a of 8.9.

Erythromycin base occurs as a bitter tasting, odorless or practically odorless, white to slight yellow, crystalline powder. Approximately 1 mg is soluble in 1 mL of water; it is soluble in alcohol.

Erythromycin estolate occurs as a practically tasteless and odorless, white, crystalline powder. It is practically insoluble in water and approximately 50 mg are soluble in 1 mL of alcohol. Erythromycin estolate may also be known as erythromycin propionate lauryl sulfate.

Erythromycin ethylsuccinate occurs as a practically tasteless and odorless, white to slight yellow, crystalline powder. It is very slightly soluble in water and freely soluble in alcohol.

Erythromycin lactobionate occurs as white to slightly yellow crystals or powder. It may have a faint odor and is freely soluble in water and alcohol.

Erythromycin may also be known as: eritromicina, and erythromycinum; many trade names are available.

Storage/Stability/Compatibility

Erythromycin (base) capsules and tablets should be stored in tight containers at room temperature (15–30°C). Erythromycin estolate preparations should be protected from light. To retain palatability, the oral suspensions should be refrigerated.

Erythromycin ethylsuccinate tablets and powder for oral suspension should be stored in tight containers at room temperature. The commercially available oral suspension should be stored in the refrigerator to preserve palatability. After dispensing, the oral suspensions are stable for at least 14 days at room temperature, but individual products may have longer labeled stabilities.

Erythromycin lactobionate powder for injection should be stored at room temperature. For initial reconstitution (vials), only sterile water for injection should be used. After reconstitution, the drug is stable for 24 hours at room temperature and 2 weeks if refrigerated. To prepare for administration via continuous or intermittent infusion, the drug is further diluted in 0.9% sodium chloride, Lactated Ringer's, or Normosol-R. Other infusion solutions may be used, but first must be buffered with 4% sodium bicarbonate injection (1 mL per 100 mL of solution). At pH's of <5.5, the drug is unstable and loses potency rapidly. Many drugs are physically **incompatible** with erythromycin lactobionate; it is suggested to consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Erythromycin 100 mg/mL for IM Injection (with 2% butyl aminobenzoate as a local anesthetic) in 100 mL vials; *Gallimycin*®-100 (Bimeda); (OTC). Approved for use in cattle, sheep, and swine. Milk withdrawal (when used as labeled) = 72 hours. Slaughter withdrawal (when used as labeled) for cattle = 14 days, sheep = 3 days, swine = 7 days.

There may also be erythromycin premixes alone and in combination with other drugs for use in swine and/or poultry.

HUMAN-LABELED PRODUCTS:

Erythromycin Base Delayed-release Tablets enteric-coated: 250 mg, 333 mg and 500 mg; *Ery-Tab*® (Abbott); (Rx)

Erythromycin Base Tablets Film-coated: 250 mg, & 500 mg; *Erythromycin Filmtabs*® (Abbott); (Rx)

Erythromycin Base Tablets with polymer coated particles: 333 mg and 500 mg; *PCE Dispertab*® (Abbott); (Rx)

Erythromycin Base Delayed-release Capsules enteric-coated pellets: 250 mg; *Eryc*® (FH Faulding & Co. Ltd.); generic; (Rx)

Erythromycin Estolate Suspension: 125 mg (as base) per 5 mL in 473 mL and 250 mg (as base) per 5 mL in 473 mL; generic (Alpharma); (Rx)

Erythromycin Stearate Film-coated tablets: 250 mg, 500 mg; *Erythrocin Stearate*® (Abbott); (Rx)

Erythromycin Ethylsuccinate Tablets: 400 mg; *E.E.S. 400*® (Abbott); generic; (Rx)

Erythromycin Ethylsuccinate Powder for Oral Suspension: 200 mg per 5 mL when reconstituted in 60 mL (400 mg only), 100 mL, 200 mL and UD 5 mL; *E.E.S.® Granules* (Abbott), *EryPed*® 200 and 400 (Abbott); (Rx)

Erythromycin Ethylsuccinate Oral Suspension: 200 mg per 5 mL in 100, 480 mL; *EES 200*® (Abbott); generic; (Rx)

Erythromycin Ethylsuccinate Oral Suspension: 400 mg per 5 mL in 100 & 480 mL; *EES 400*® (Abbott) (Rx); generic; (Rx)

Erythromycin Ethylsuccinate Oral Suspension: 100 mg per 2.5 mL in 50 mL; *EryPed Drops*® (Abbott); (Rx)

Erythromycin Lactobionate Powder for Injection: 500 mg and 1 g (as lactobionate) in vials, piggyback vials and ADD-Vantage vials; *Erythrocin*® (Abbott); (Rx); generic; (Rx)

Erythromycin & Sulfisoxazole Granules for Oral Suspension: erythromycin ethylsuccinate (equivalent to 200 mg erythromycin activity) and sulfisoxazole acetyl (equivalent to 600 mg sulfisoxazole) per 5 mL when reconstituted in 100 mL, 150 mL & 200 mL; *Eryzole*® (Alra); *Pediazole*® (Ross); generic; (Rx)

Topical and ophthalmic preparations are also available.

ESMOLOL HCL

(ess-moe-lol) Brevibloc®

BETA-1 BLOCKER

Prescriber Highlights

- ▶ Ultra-short acting beta₁-blocker used IV for short-term treatment of SVT's or to determine if beta-blockers are effective for controlling arrhythmias
- ▶ Contraindications: Patients with overt cardiac failure, 2nd or 3rd degree AV block, sinus bradycardia, or in cardiogenic shock
- ▶ Caution: Patients with CHF, bronchoconstrictive lung disease, or diabetes mellitus
- ▶ Adverse Effects: Hypotension & bradycardia are the effects most likely seen

Uses/Indications

Esmolol may be used as test drug to indicate whether beta-blocker therapy is warranted as an antiarrhythmic agent, particularly in cats with hypertrophic cardiomyopathy, or as an infusion in the short-term treatment of supraventricular tachyarrhythmias (e.g., atrial fibrillation/flutter, sinus tachycardia).

Pharmacology/Actions

Esmolol primarily blocks both beta₁-adrenergic receptors in the myocardium. At clinically used doses, esmolol does not have any intrinsic sympathomimetic activity (ISA) and unlike propranolol, does not possess membrane-stabilizing effects (quinidine-like) or bronchoconstrictive effects. Cardiovascular effects secondary to esmolol include negative inotropic and chronotropic activity that can lead to reduced myocardial oxygen demand. Systolic and diastolic blood pressures are reduced at rest and during exercise. Esmolol's antiarrhythmic effect is thought to be due to its blockade of adrenergic stimulation of cardiac pacemaker potentials. Esmolol increases

es sinus cycle length, slows AV node conduction, and prolongs sinus node recovery time.

Pharmacokinetics

After IV injection esmolol is rapidly and widely distributed but not appreciably to the CNS, spleen or testes. The distribution half-life is about 2 minutes. Steady-state blood levels occur in about 5 minutes if a loading dose was given or about 30 minutes if no load was given. It is unknown whether the drug crosses the placenta or enters milk. Esmolol is rapidly metabolized in the blood by esterases to a practically inactive metabolite. Renal or hepatic dysfunction do not appreciably alter elimination characteristics. Terminal half-life is about 10 minutes and duration of action after discontinuing IV infusion is usually about 20 minutes post-infusion in dogs.

Contraindications/Precautions/Warnings

Esmolol is contraindicated in patients with overt cardiac failure, 2nd or 3rd degree AV block, sinus bradycardia, or in cardiogenic shock. It should be used with caution (weigh benefit vs. risk) in patients with CHF, bronchoconstrictive lung disease, or diabetes mellitus.

Adverse Effects

At usual doses adverse effects are uncommon and generally are an extension of the drug's pharmacologic effects. Hypotension (with resultant clinical signs) and bradycardia are the most likely adverse effects seen. These usually prove mild and transient in nature. Esmolol may mask certain clinical signs of developing hypoglycemia (such as increased heart rate or blood pressure).

Reproductive/Nursing Safety

Studies done in rats and rabbits demonstrated no teratogenic effects at doses up to 3 times the maximum human maintenance dose (MHMD). Higher doses (8 times or more MHMD) demonstrated some maternal death and fetal resorption.

It is unknown if esmolol is excreted in milk.

Overdosage/Acute Toxicity

The IV LD₅₀ in dogs is approximately 32 mg/kg. Dogs receiving 2 mg/kg per minute for one hour showed no adverse effects; doses of 3 mg/kg/minute for one hour produced ataxia and salivation and 4 mg/kg/minute for one hour caused muscular rigidity, tremors, seizures, ptosis, vomiting, hyperpnea, vocalizations, and prostration. These effects all resolved within 90 minutes of the end of infusion. Because of the short duration of action of the drug, discontinuation or dosage reduction may be all that is required; otherwise, symptomatic and supportive treatment may be initiated.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving esmolol and may be of significance in veterinary patients:

- **DIGOXIN:** Esmolol may increase serum digoxin levels up to 20%, but these drugs have been used together safely and effectively
- **MONOAMINE OXIDASE INHIBITORS:** Concurrent use of monoamine oxidase inhibitors with esmolol is not recommended due to potential risk of hypertension
- **MORPHINE:** Titrate esmolol dosage carefully in patients also receiving morphine as it may increase steady-state esmolol serum concentrations up to 50%.
- **RESERPINE:** May see additive effects (hypotension, bradycardia) if used with esmolol
- **VASOCONSTRICTORS/INOTROPES** (e.g., dopamine, epinephrine, norepinephrine): If systemic vascular resistance is high, there is an in-

crease risk for blocked cardiac contractility; esmolol is not recommended to control SVT's in patients receiving these drugs

- **VERAPAMIL:** In humans, particularly with severe cardiomyopathy, cardiac arrest has occurred (rarely)

Doses

■ DOGS:

For ultra-short acting beta blockade (for treating or assisting in treatment of ventricular arrhythmias):

- a) Can be administered two ways: **1)** An initial loading dose of 0.25–0.5 mg/kg (250–500 mcg/kg) administered IV as slow bolus over 1–2 minutes, then followed by a constant rate infusion of 10–200 mcg/kg/minute; or **2)** Start CRI at 10–200 mcg/kg/minute without the bolus loading dose. If no loading dose, maximal effect should occur in 10–20 minutes. Use of a loading dose and the high end of the infusion rate dose should only be used in dogs with normal cardiac function. In dogs with severe dilated cardiomyopathy or severe mitral regurgitation do not give loading dose and start CRI at 10–20 mcg/kg/min and titrate upward every 10 minutes to an effective endpoint. (Kittleson 2006c)
- b) For SVTs: 0.05–0.1 mg/kg (50–100 mcg/kg) IV bolus over 2 minutes; repeat every 5 minutes to a maximum of 0.5 mg/kg (500 mcg/kg). (Fine 2006), (Rush 2005b)
- c) Loading dose of 200–500 mcg/kg IV over 1 minute; followed by a constant rate IV infusion of 25–200 mcg/kg/minute (Ware 2000)
- d) Give incremental doses of 0.05–0.1 mg/kg boluses every 5 minutes to a maximum dose of 0.5 mg/kg; or as an infusion of 50–200 micrograms/kg/min. If arrhythmia conversion does not occur, then other drugs with negative inotropic effects (e.g., diltiazem or verapamil) may be given 30 minutes after esmolol administration. (Russell and Rush 1995)

■ CATS:

For ultra-short acting beta blockade for treating or assisting in treatment of ventricular arrhythmias, or in cats with HCM to determine if beta-blockers will reduce the dynamic left-ventricular outflow tract obstruction resulting from systolic anterior motion of the mitral valve:

- a) In cats with HCM: An initial loading dose of 0.25–0.5 mg/kg (250–500 mcg/kg) administered IV as slow bolus over 1–2 minutes, then followed by a constant rate infusion of 10–200 mcg/kg/minute. (Kittleson 2006c)
- b) Loading dose of 200–500 mcg/kg IV over 1 minute; followed by a constant rate IV infusion of 25–200 mcg/kg/minute (Ware 2000)

Monitoring

- Blood Pressure
- ECG
- Heart Rate

Client Information

- Esmolol should only be used in an in-patient setting where appropriate monitoring is available.

Chemistry/Synonyms

A short acting beta₁-adrenergic blocker, esmolol occurs as white or off white crystalline powder. It is not as lipophilic as either labetalol or propranolol, but is comparable to acebutolol. 650 mg are soluble in one mL of water and 350 mg are soluble in one mL of alcohol.

Esmolol HCl may also be known as ASL-8052, *Brevibloc*® or *Miniblock*®.

Storage/Stability/Compatibility

The concentrate for injection should be stored at room temperature; do not freeze and protect from excessive heat. It is a clear, colorless to light yellow solution. Expiration dates of 3 years are assigned after manufacture.

After diluted to a concentration of 10 mg/mL esmolol HCl is stable (at refrigeration temperatures or room temperature) for at least 24 hours in commonly used IV solutions. Esmolol may be diluted in standard D5, LRS or saline (or combinations thereof) IV fluids. At this concentration it is reportedly physically **compatible** with digoxin, dopamine, fentanyl, lidocaine, morphine sulfate, nitroglycerin, and nitroprusside. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Esmolol HCl Injection: 10 mg/mL in 10 mL vials, 20 mg/mL in 5 mL vials and 100 mL bags, and 250 mg/mL in 10 mL amps; *Brevibloc*® (Baxter); generic; (Rx)

ESTRADIOL CYPIONATE

(ess-tra-dye-ole) ECP®

HORMONAL AGENT (ESTROGEN)

Prescriber Highlights

- ▶ Natural estrogen salt used primarily to induce estrus; has been used as an abortifacient (but rarely recommended today)
- ▶ Contraindications: Pregnancy (abortifacient, teratogen); the FDA has stated that the use of ECP in food animals is illegal
- ▶ Adverse Effects: In CATS & DOGS: bone marrow toxicity, cystic endometrial hyperplasia, pyometra;
- ▶ In male animals, feminization may occur; in females, signs of estrus may occur;
- ▶ In CATTLE: Prolonged estrus, genital irritation, decreased milk flow, precocious development, & follicular cysts may develop
- ▶ Drug Interactions

Uses/Indications

For mares, indications for the use of estradiol include induction of estrus during the non-breeding or breeding seasons and to enhance the mare's uterine defense mechanism. Estradiol cypionate has historically been used as an abortifacient agent in cattle, cats and dogs. Estrogens are no longer recommended by most theriogenologists for use as an abortifacient in small animals. The FDA stated (April 5, 2006): "The use of ECP in food-producing animals is illegal, and manufacturing and compounding of ECP for such use is illegal."

Pharmacology/Actions

The most active endogenous estrogen, estradiol possesses the pharmacologic profile expected of the estrogen class. Estrogens are necessary for the normal growth and development of the female sex organs and in some species contribute to the development and maintenance of secondary female sex characteristics. Estrogens cause increased cell height and secretions of the cervical mucosa, thickening of the vaginal mucosa, endometrial proliferation, and increased uterine tone.

Estrogens have effects on the skeletal system. They increase calcium deposition, accelerate epiphyseal closure, and increase bone formation. Estrogens have a slight anabolic effect and can increase sodium and water retention.

Estrogens affect the release of gonadotropins from the pituitary gland. This can cause inhibition of lactation, ovulation, and androgen secretion.

Pharmacokinetics

No specific information was located regarding the pharmacokinetics of estradiol in veterinary species. In humans, estrogen in oil solutions after IM administration are absorbed promptly and absorption continues over several days. Esterified estrogens (*e.g.*, estradiol cypionate) have delayed absorption after IM administration. Estrogens are distributed throughout the body and accumulate in adipose tissue. Elimination of the steroidal estrogens occurs principally by hepatic metabolism. Estrogens and their metabolites are primarily excreted in the urine, but are also excreted into the bile where most is reabsorbed from the GI.

Contraindications/Precautions/Warnings

Estradiol is contraindicated during pregnancy as it can cause fetal malformations of the genitourinary system and induce bone marrow depression in the fetus.

Estradiol cypionate should not be used to treat estrogen-responsive incontinence in small animals; other estrogens (DES, conjugated estrogens) are less toxic.

In cases of prolonged corpus luteum in cows, a thorough uterine exam should be completed to determine if endometritis or a fetus is present.

Estradiol is reportedly very toxic (bone marrow) to ferrets.

Adverse Effects

Estrogens have been associated with severe adverse reactions in small animals. In cats and dogs, estrogens are considered toxic to the bone marrow and can cause blood dyscrasias. Blood dyscrasias are more prevalent in older animals and if higher dosages are used. Initially, a thrombocytosis and/or leukocytosis may be noted, but thrombocytopenia/leukopenias will gradually develop. Changes in a peripheral blood smear may be apparent within two weeks after estrogen administration. Chronic estrogen toxicity may be characterized by a normochromic, normocytic anemia, thrombocytopenia, and neutropenia. Bone marrow depression may be transient and begin to resolve within 30–40 days or may persist or progress to a fatal aplastic anemia.

Estrogens may cause cystic endometrial hyperplasia and pyometra. After therapy is initiated, an open-cervix pyometra may be noted 1–6 weeks after therapy.

Estrogens may induce mammary neoplasia.

When used chronically in male animals, feminization may occur. In females, signs of estrus may occur and persist for 7–10 days.

In cattle, prolonged estrus, genital irritation, decreased milk-flow, precocious development, and follicular cysts may develop after estrogen therapy. These effects may be secondary to overdosage and dosage adjustment may reduce or eliminate them.

Reproductive/Nursing Safety

Estradiol is contraindicated during pregnancy. In humans, the FDA categorizes this drug as category **X** for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **D** (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

Estrogens have been shown to decrease the quantity and quality of maternal milk.

Overdosage/Acute Toxicity

No reports of inadvertent acute overdosage in veterinary patients were located; see Adverse Effects above.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving estradiol and may be of significance in veterinary patients:

- **AZOLE ANTIFUNGALS** (fluconazole, itraconazole, ketoconazole): May increase estrogen levels
- **CORTICOSTEROIDS**: Enhanced glucocorticoid effects may result if estrogens are used concomitantly with corticosteroid agents. It has been postulated that estrogens may either alter the protein binding of corticosteroids and/or decrease their metabolism; corticosteroid dosage adjustment may be necessary when estrogen therapy is either started or discontinued
- **MACROLIDE ANTIBIOTICS** (erythromycin, clarithromycin): May increase estrogen levels
- **PHENOBARBITAL**: May decrease estrogen activity if administered concomitantly
- **RIFAMPIN**: May decrease estrogen activity if administered concomitantly
- **ST. JOHN'S WORT**: May decrease estrogen activity if administered concomitantly
- **WARFARIN**: Oral anticoagulant activity may be decreased if estrogens are administered concurrently; increases in anticoagulant dosage may be necessary if adding estrogens

Laboratory Considerations

- Estrogens in combination with progestins (e.g., oral contraceptives) have been demonstrated in humans to increase **thyroxine-binding globulin (TBG)** with resultant increases in total circulating thyroid hormone. Decreased T₃ resin uptake also occurs, but free T₄ levels are unaltered. It is unclear if estradiol affects these laboratory tests in veterinary patients.

Doses

■ DOGS:

For pregnancy avoidance after mismating:

Note: This drug is rarely used for this indication today.

- a) 0.02 mg/kg (ECP) IM within 72 hours of mating (Burke 1986)
- b) 0.044 mg/kg (ECP) IM once during 3–5 days of standing heat or within 72 hours of mismating (Woody 1988)
- c) 0.044 mg/kg (ECP), not to exceed 1 mg total dose, IM once administered during estrus or early diestrus (Olson et al. 1986)

■ CATS:

For pregnancy avoidance after mismating:

Note: This drug is rarely used for this indication today.

- a) 0.125–0.25 mg (ECP) IM within 40 hours of mating (Wildt 1986)
- b) 0.125–0.25 mg (ECP) IM within 3–5 days of coitus (Woody 1988)

■ CATTLE:

The FDA has stated that the use of ECP in food-producing animals is illegal.

■ HORSES:

For induction of estrus during the non-breeding season:

- a) 10 mg estradiol cypionate will result in estrus 2–3 days after treatment (Squires and McKinnon 1987)

For treatment of mares with estrogen-responsive incontinence:

- a) 4–10 mcg/kg estradiol cypionate IM daily for three days and then every other day. Some mares will improve, but does not “cure.” (Schott II and Carr 2003)

For induction of estrus in mares with “silent heat” during breeding season:

- a) 1 mg estradiol (Squires and McKinnon 1987)

To enhance the mare’s uterine defense mechanism:

- a) 1–2 mg estradiol daily for 3–5 days (Squires and McKinnon 1987)

Monitoring

When therapy is either at high dosages or chronic, see adverse effects for more information. Done at least monthly:

- Packed Cell Volumes (PCV)
- White blood cell counts (CBC)
- Platelet counts; Baseline, one month after therapy, and repeated two months after cessation of therapy if abnormal
- Liver function tests

Chemistry/Synonyms

Estradiol is a naturally occurring steroidal estrogen. Estradiol cypionate is produced by esterifying estradiol with cyclopentanepropionic acid, and occurs as a white to practically white, crystalline powder. It is either odorless or may have a slight odor and has a melting range of 149–153°C. Less than 0.1 mg/mL is soluble in water and 25 mg/mL is soluble in alcohol. Estradiol cypionate is sparingly soluble in vegetable oils.

Estradiol may also be known as: beta-oestradiol, dihydrofolliculin, dihydrotheelin, dihydroxyoestrin, estradiolum, NSC-9895, NSC-20293 (alpha-estradiol), and oestradiol; many trade names are available.

Estradiol Cypionate may also be known as: oestradiol cyclopentylpropionate, oestradiol cypionate, *Delestrogen*®, *Depo-Estradiol*®, *Depogen*®, *Dura-Estrin*®, *ECP*®, *E-Cypionate*®, *Estra-D*®, *Estrace*®, *Estro-Cyp*®, *Estroject*®, *depGynogen*®, *Femtrace*®, or *Gynodiol*®.

Storage/Stability/Compatibility

Estradiol cypionate should be stored in light-resistant containers at temperatures of less than 40°C, preferably at room temperature (15–30°C); avoid freezing.

Commercially available injectable solutions of estradiol cypionate are sterile solutions in a vegetable oil (usually cottonseed oil); they may contain chlorobutanol as a preservative.

It is not recommended to mix estradiol cypionate with other medications.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

There are several estradiol-containing implants for use in beef cattle.

HUMAN-LABELED PRODUCTS:

Estradiol Cypionate in Oil for Injection: 5 mg/mL in 5 mL vials; *Depo-Estradiol*® (Pharmacia); (Rx)

Estradiol Valerate in Oil for Injection: 10 mg/mL, 20 mg/mL & 40 mg/mL in 5 mL vials; *Delestrogen*® (Monarch); (Rx)

Estradiol Tablets: 0.45 mg, 0.5 mg, 0.9 mg, 1 mg, 1.5 mg, 1.8 mg and 2 mg micronized estradiol; *Estrace*® (Warner Chilcott), *Gynodiol*® (Fielding), *Femtrace*® (Warner Chilcott); generic; (Rx)

ETHACRYNIC ACID ETHACRYNATE SODIUM

(eth-a-krin-ik) Edecrin®

LOOP DIURETIC**Prescriber Highlights**

- ▶ Rarely-used loop diuretic similar to furosemide; may have greater ototoxicity & GI effects than furosemide
- ▶ Contraindications: Patients with anuria, hypersensitivity, or seriously depleted electrolytes
- ▶ Caution: Patients with pre-existing electrolyte or water balance abnormalities, impaired hepatic function, & diabetes mellitus
- ▶ Adverse Effects: Fluid & electrolyte abnormalities. Others include ototoxicity, GI distress, hematologic effects, weakness, & restlessness
- ▶ Drug Interactions

Uses/Indications

Ethacrynic acid is a loop diuretic that shares the same indications as furosemide (congestive cardiomyopathy, pulmonary edema, hypercalcemic nephropathy, uremia, as adjunctive therapy in hyperkalemia and, occasionally, as an antihypertensive agent). Its use has been largely supplanted in the armamentarium by furosemide for these indications.

Ethacrynic acid may be useful in the treatment of nephrogenic diabetes insipidus as it may cause a paradoxical decrease in urine volume. Other uses include the adjunctive treatment of hypercalcemia and to increase the excretion of bromide in the treatment of bromide toxicity.

Pharmacology/Actions

Ethacrynic acid reduces the absorption of electrolytes in the ascending section of the loop of Henle, decreases the reabsorption of both sodium (to a much greater extent than the thiazides) and chloride, increases the excretion of potassium in the distal renal tubule, and directly effects electrolyte transport in the proximal tubule. The exact mechanisms of ethacrynic acid's effects have not been established. It has no effect on carbonic anhydrase nor does it antagonize aldosterone. Ethacrynic acid increases renal excretion of water, sodium, potassium, chloride, calcium, magnesium, hydrogen, ammonium, and bicarbonate.

Pharmacokinetics

Ethacrynic acid is absorbed rapidly and nearly completely from the GI tract. It does not enter the CNS and accumulates in the liver. It is unknown if ethacrynic acid crosses the placenta or enters milk. Ethacrynic acid is metabolized in the liver and also secreted via the proximal tubules into the urine. Serum half-lives in humans averages around one hour. Duration of effect is about 6–8 hours after oral dosing; about 2 hours after IV administration.

Contraindications/Precautions/Warnings

Ethacrynic acid is contraindicated in patients with anuria, are hypersensitive to the drug, or have seriously depleted electrolytes. Ethacrynic acid is also contraindicated in human infants (safety not established).

Ethacrynic acid should be used with caution in patients with pre-existing electrolyte or water balance abnormalities, impaired hepatic function (may precipitate hepatic coma), and diabetes mellitus. Patients with conditions that may lead to electrolyte or water balance abnormalities (e.g., vomiting, diarrhea, etc.) should be monitored carefully.

Adverse Effects

Ethacrynic acid may induce fluid and electrolyte abnormalities. Patients should be monitored for hydration status and electrolyte imbalances (especially potassium, calcium and sodium). Other potential adverse effects include ototoxicity (especially in cats with high dose IV therapy), gastrointestinal disturbances, hematologic effects (anemia, leukopenia), weakness, and restlessness. Ethacrynic acid is thought to have a greater incidence of ototoxicity and GI effects than furosemide.

Reproductive/Nursing Safety

A study where pregnant dogs received 5 mg/kg daily demonstrated no teratogenic effects or effects on the pregnancy. It is unknown whether the drug enters milk. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is unknown if ethacrynic acid is distributed into milk.

Overdosage/Acute Toxicity

The LD₅₀ in dogs after oral administration is >1000 mg/kg; after IV injection >300 mg/kg. Chronic overdosing at 10 mg/kg for six months in dogs led to development of calcification and scarring of the renal parenchyma.

Acute overdosage may cause electrolyte and water balance problems, CNS effects (lethargy to coma and seizures) and cardiovascular collapse.

Treatment consists of emptying the gut after recent oral ingestion, using standard protocols. Avoid giving concomitant cathartics as they may exacerbate the fluid and electrolyte imbalances that can occur. Aggressively monitor and treat electrolyte and water balance abnormalities supportively. Additionally, monitor respiratory, CNS, and cardiovascular status; treat supportively and symptomatically, if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ethacrynic acid and may be of significance in veterinary patients:

- **ACE INHIBITORS** (e.g., **enalapril**, **benazepril**): Increased risks for hypotension, particularly in patients who are volume or sodium depleted secondary to diuretics
- **AMINOGLYCOSIDES** (**gentamicin**, **amikacin**, etc.): Increased risk for nephro- or ototoxicity
- **AMPHOTERICIN B**: Loop diuretics may increase the risk for nephrotoxicity development; hypokalemia
- **CORTICOSTEROIDS**: Increased risk for GI ulceration; hypokalemia
- **DIGOXIN**: Ethacrynic acid-induced hypokalemia may increase the potential for digoxin toxicity
- **INSULIN**: Ethacrynic acid may alter insulin requirements
- **MUSCLE RELAXANTS**: Ethacrynic acid may inhibit the muscle relaxation qualities of tubocurarine, but increase the effects of succinylcholine
- **PROBENECID**: Can reduce the diuretic efficacy of ethacrynic acid, and ethacrynic acid may reduce probenecid's uricosuric effects
- **SALICYLATES**: Loop diuretics can reduce the excretion of salicylates
- **THEOPHYLLINE**: Pharmacologic effects of theophylline may be enhanced when used with ethacrynic acid

Doses

■ DOGS & CATS:

- a) 0.2–0.4 mg/kg IM or IV q4–12h (Allen, Pringle et al. 1993)

Monitoring

- Serum electrolytes, BUN, creatinine, glucose
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema, patient weight, if indicated
- Evaluation of ototoxicity, particularly with prolonged therapy or in cats

Client Information

- Recommend administering dosage with meals when possible.
- Clients should contact veterinarian if clinical signs of water or electrolyte imbalance occur; excessive thirst, lethargy, lassitude, restlessness, oliguria, GI distress, or tachycardia

Chemistry/Synonyms

A loop diuretic, ethacrynic acid occurs as a white or nearly white, odorless or practically odorless crystalline powder. It is very slightly soluble in water and freely soluble in alcohol.

Ethacrynic acid may also be known as etacrynic acid, acidum etacrynicum, etacrynsaure, MK-595, NSC-85791, *Edecril*®, *Edecrin*®, *Reomax*®, and *Uregyt*®.

Storage/Stability

Ethacrynic acid tablets should be stored at room temperature in well-closed containers. An expiration date of 5 years is assigned at the time of manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Ethacrynic Acid Tablets: 25 mg, & 50 mg; *Edecrin*® (Merck); (Rx)

Ethacrynate Sodium Powder for Injection: 50 mg ethacrynic sodium/50 mL vial for reconstitution; *Edecrin*® Sodium (Merck); (Rx)

ETHAMBUTOL HCL

(e-*tham*-byoo-tole) Myambutol®, Etibi®

ORAL ANTIMYCOBACTERIAL ANTIBIOTIC

Prescriber Highlights

- Can be used as an ingredient in an antimycobacterial “cocktail” for dogs, cats, birds
- Treating these infections is controversial because of potential public health risks associated with the infections
- Optic or neuro toxicity greatest concern

Uses/Indications

In combination with other antimycobacterial drugs, ethambutol may be useful in treating mycobacterial infections caused by *M. bovis*, *M. tuberculosis*, *M. genavense*, *M. avium-intracellulare* complex (MAC) in dogs or cats, particularly when the organism is resistant to treatment with other drug combinations (rifampin, enrofloxacin, azithromycin). In birds, ethambutol has been used in combination with other agents for treating mycobacterial (e.g., *M. avium*) infections.

Because of public health risks, particularly in the face of increased populations of immunocompromised people, treatment of mycobacterial (*M. bovis*, *M. tuberculosis*, etc.) infections in domestic or captive animals is controversial.

Pharmacology/Actions

A synthetic, bacteriostatic, antimycobacterial agent, ethambutol's exact mechanism of action is not known. Ethambutol is only active against actively dividing mycobacteria. It enters mycobacterial cells and interferes with RNA synthesis. Ethambutol does not have appreciable activity against other bacteria or fungi. Resistance can occur and is thought to develop in a step-wise manner. Cross-resistance with other antimycobacterial agents has not been reported.

Pharmacokinetics

Pharmacokinetic values for cats or birds were not located. In dogs, ethambutol is reported to have a volume of distribution of 3.8 L/kg, a total body clearance of 13.2 mL/min/kg, and an elimination half-life of 4.1 hours. Nephrectomized dogs had an elimination half-life of 5 hours.

In humans, ethambutol is rapidly absorbed after PO administration and bioavailability is around 75%. The drug is distributed widely in the body, but CSF levels only range from 10–50% of those found in serum. Erythrocyte concentrations are about twice that of the serum and can serve as a depot for the drug. About 15% of absorbed drug is hepatically metabolized to inactive metabolites. The majority of the drug is eliminated both by tubular secretion and glomerular filtration as unchanged drug in the urine. Elimination half-life in humans with normal renal function is about 3–4 hours; up to 8 hours if renal function is impaired.

Contraindications/Precautions/Warnings

Ethambutol should not be used in patients with a history of prior hypersensitivity reactions to it.

Patients with markedly reduced renal function may need dosage adjustment.

Adverse Effects

Well-described adverse effect profiles for ethambutol in dogs, cats or birds are not available. Because ethambutol is used in combination with other medications, adverse effects associated with treatment

may not be a result of ethambutol. In pre-clinical studies, some dogs receiving ethambutol over prolonged periods developed non-dose related degenerative changes in the central nervous system. In toxicology studies, dogs receiving large, prolonged doses developed signs of myocardial toxicity and depigmentation of the tapetum lucidum of the eyes. However, doses as large as 400 mg/kg/day for 4 weeks in dogs demonstrated no significant abnormalities in electroretinogram or visual evoked potential. In humans, optic neuritis (usually reversible after drug discontinuation) causing decreased visual acuity has been reported; routine ophthalmologic exams are recommended for humans taking this medication long-term.

Reproductive/Nursing Safety

Ethambutol crosses the placenta; fetal levels are reported to range from 30–75% of that found in maternal serum. Teratogenic effects associated with ethambutol have not been reported in humans, but studies in mice, rats, and rabbits given high doses yielded a variety of abnormalities in offspring. Although risks exist, most believe that ethambutol is relatively safe to use during human pregnancy and untreated tuberculosis poses a much greater risk to the fetus.

Ethambutol is excreted into milk in levels approximating those found in maternal serum. While no problems have been documented and it is most likely safe, risk to offspring cannot be ruled out.

Overdosage/Acute Toxicity

Very limited information exists. Acute overdoses of greater than 10 grams in humans have caused optic neuritis. Other adverse effects noted with human overdoses can include: CNS effects (confusion, visual hallucinations), abdominal pain, nausea, fever and headache; treatment is supportive.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ethambutol and may be of significance in veterinary patients:

- **ALUMINUM-CONTAINING ANTACIDS:** In humans, it has been documented that co-administration can reduce oral absorption of ethambutol; it is suggested to separate dosing by at least 4 hours if both drugs are necessary

Laboratory Considerations

No specific concerns; in humans, increased **serum uric acid** levels have been noted

Doses

■ DOGS:

- a) For treatment of disseminated *M. tuberculosis*: Ethambutol: 10–25 mg/kg PO once daily, in combination with rifampin (5–10 mg/kg PO q12–24h; maximum of 600 mg/day) and isoniazid (10–20 mg/kg PO once daily; maximum of 300 mg/day). May also add pyrazinamide at 15–40 mg/kg PO once daily. **Note:** pyrazinamide is ineffective for *M. bovis*. Treatment must continue for more than 9 months. (Greene and Gunn-Moore 2006)

■ CATS:

- a) For treatment of feline tuberculosis: Initial treatment phase with rifampin (10–20 mg/kg PO q12–24h); enrofloxacin (5 mg/kg PO q12–24h); azithromycin (5–10 mg/kg PO q12–24h) for the first two months, then continuation phase (for approximately another 4 months) with rifampin and either enrofloxacin or azithromycin. If resistance develops, rifampin, isoniazid (10–20 mg/kg PO once daily) and ethambutol (15 mg/kg PO once daily) may be considered. If

only two drugs are required, suggest using only rifampin and isoniazid. (Hartmann and Greene 2005)

■ BIRDS:

- a) For treatment of *M. avium* infections in caged birds: Several protocols have been used, but controlled trials have not been performed. Combination therapy and treatment for 6–12 months is required.

Protocol 1: Ciprofloxacin 20 mg/kg PO q12h or Enrofloxacin 15 mg/kg PO or IM (**Note:** repeated IM injections can cause muscle necrosis) for 10 days; Clofazimine 1.5 mg/kg PO once daily; Cycloserine 5 mg/kg PO q12h; and Ethambutol 20 mg/kg PO q12h.

Protocol 2: Clofazimine 6 mg/kg PO once daily; Ethambutol 30 mg/kg PO once daily; Rifampin 45 mg/kg PO once daily.

Protocol 3: Ciprofloxacin 80 mg/kg PO once daily or Enrofloxacin 30 mg/kg PO once daily; Ethambutol 30 mg/kg PO once daily; Rifampin 45 mg/kg PO once daily or Rifabutin 15 mg/kg PO once daily. (Phalen 2006)

- b) For Avian mycobacteriosis: All are dosed PO once daily for 9–12 months: Rifabutin 45–55 mg/kg; Clarithromycin 60–85 mg/kg; Ethambutol 30–85 mg/kg; Enrofloxacin 20 mg/kg. (Flammer 2006)

Monitoring

- Clinical efficacy
- With long-term therapy, consider periodic monitoring of visual, liver, and renal function; CBC

Client Information

- Clients must be informed of the potential public health issues associated with mycobacterium infections and should be encouraged to contact a physician, preferably an infectious disease specialist for guidance
- Treatment can be very prolonged (many months) and expensive
- May be administered with or without food
- Report any changes noted with patient's eyes or vision to the veterinarian

Chemistry/Synonyms

Ethambutol HCl occurs as a white, crystalline powder that is freely soluble in water and soluble in alcohol.

Ethambutol may also be known as: CL-40882, etambutol, or ethambutoli; there are many trade names for international products.

Storage/Stability

Ethambutol tablets should be stored below 40°C and preferably, between 15–30°C in well-closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ethambutol HCl Tablets: 100 mg, & 400 mg (scored); *Myambutol*® (X-Gen); (Rx)

ETHANOL ALCOHOL, ETHYL

(eth-a-nol) Alcohol

ANTIDOTE

Prescriber Highlights

- ▶ Used for treatment of ethylene glycol or methanol toxicity
- ▶ Contraindications: None (above are life threatening)
- ▶ Adverse Effects: CNS depression, diuresis, pain, & infection at the injection site.
- ▶ Avoid extravasation
- ▶ Monitor fluid & electrolyte status, alcohol & toxin levels (if possible)

Uses/Indications

The principal use of ethanol in veterinary medicine is for the treatment of ethylene glycol or methanol toxicity. While fomepizole (4-methyl pyrazole) is now the treatment of choice for ethylene glycol poisoning, alcohol is a readily available and an economical alternative when patients present within a few hours after ingestion.

Percutaneous injection of ethanol 95% has been used successfully to treat feline hyperthyroidism.

Ethyl alcohol has also been used in aerosol form as a mucokinetic agent in horses.

Pharmacology/Actions

By competitively inhibiting alcohol dehydrogenase, alcohol can prevent the formation of ethylene glycol to its toxic metabolites (glycolaldehyde, glycolate, glyoxalate, and oxalic acid). This allows the ethylene glycol to be principally excreted in the urine unchanged. A similar scenario exists for the treatment of methanol poisoning. For alcohol to be effective, however, it must be given very early after ingestion; it is seldom useful if started 8 hours after a significant ingestion.

Pharmacokinetics

Alcohol is well absorbed orally, but is administered intravenously for toxicity treatment. It rapidly distributes throughout the body and crosses the blood-brain barrier. Alcohol crosses the placenta.

Contraindications/Precautions/Warnings

Because ethylene glycol and methanol intoxications are life threatening, there are no absolute contraindications to ethanol's use for these indications.

Use of ethanol with fomepizole is usually contraindicated; see drug interactions for more information.

Adverse Effects

The systemic adverse effects of alcohol are quite well known. The CNS depression and respiratory depression associated with the high levels used to treat ethylene glycol and methanol toxicity can confuse the clinical monitoring of these toxicities. Ethanol's effects on antidiuretic hormone may enhance diuresis. As both ethylene glycol and methanol may also cause diuresis, fluid and electrolyte therapy requirements need to be monitored and managed. Hypocalcemia and metabolic acidosis may be noted and pulmonary edema can occur. Other adverse effects include pain and infection at the injection site and phlebitis. Extravasation should be watched for and avoided. When aerosolized in horses, irritation and bronchoconstriction may result.

Reproductive/Nursing Safety

Alcohol's safety during pregnancy has not been established for short-term use. Use only when necessary. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Alcohol passes freely into milk in levels that approximate maternal serum levels, but it is unlikely to have negative effects on nursing offspring.

Overdosage/Acute Toxicity

If clinical signs of overdosage occur, either slow the infusion or discontinue temporarily. Alcohol blood levels may be used to monitor both efficacy and toxicity of alcohol.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ethanol and may be of significance in veterinary patients:

- **BROMOCRIPTINE:** Alcohol may increase the severity of side effects seen with bromocriptine
- **CHARCOAL, ACTIVATED:** Will inhibit absorption of orally administered ethanol; do not use activated charcoal if administering ethanol orally for methanol or ethylene glycol intoxication
- **CNS DEPRESSANT DRUGS** (e.g., **barbiturates, benzodiazepines, phenothiazines**, etc.): Alcohol may cause additive CNS depression when used with other CNS depressant drugs
- **FOMEPIZOLE (4-MP):** Inhibits alcohol dehydrogenase; ethanol metabolism is reduced significantly and alcohol poisoning (CNS depression, coma, death) can occur. Use together is generally not recommended, but if both drugs are used, monitoring of ethanol blood levels is mandatory.
- **INSULIN and other antidiabetic drugs:** Alcohol may affect glucose metabolism and the actions of insulin or oral antidiabetic agents
- A disulfiram reaction (increased acetaldehyde with tachycardia, vomiting, weakness) may occur if alcohol is used concomitantly with the following drugs: **cefoperazone, chlorpropamide, furazolidone, metronidazole**

Doses

■ DOGS:

For ethylene glycol poisoning:

- a) As a 20% solution, give 5.5 mL/kg IV q4h for 5 treatments, then q6h for four additional treatments (Forrester and Lees 1994)
- b) Using a 5% solution, give 22 mL/kg IV every 4 hours for 24 hours, then every 6 hours for another 24 hours; alternatively give a constant rate IV infusion to run at 5.5 mL/kg/hr (Firth 2000)

■ CATS:

For ethylene glycol poisoning:

- a) As a 20% solution, give 5 mL/kg IV q6h for 5 treatments, then q8h for four additional treatments (Forrester and Lees 1994)
- b) Using a 5% solution, give a constant rate IV infusion to run at 5 mL/kg/hr (Firth 2000)

Monitoring

- Alcohol blood levels (and ethylene glycol or methanol levels). **Note:** In humans, blood ethanol levels should be maintained at 100 to 130 milligrams/deciliter (21.7 to 28.2 milliMoles/liter). It is safer to maintain a blood ethanol concentration greater than

130 milligrams/deciliter than to have it fall below 100 milligrams/deciliter. (*POISINDEX® Management*, Thompson; *MICROMEDEX® Healthcare Series*, 2007)

- Degree of CNS effect
- Fluid/electrolyte status

Client Information

- Systemically administered alcohol should be given in a controlled clinical environment.

Chemistry/Synonyms

A transparent, colorless, volatile liquid having a characteristic odor and a burning taste, ethyl alcohol is miscible with water and many other solvents.

Ethanol may also be known as aethanolum, alcool, grain alcohol, ethanolum, and ethyl alcohol.

Storage/Stability/Compatibility/Preparation

Alcohol should be protected from extreme heat or freezing. Do not use unless the solution is clear. Alcohol may precipitate many drugs; do not administer other medications in the alcohol infusion solution unless compatibility is documented (consult specialized references or a hospital pharmacist for more specific information).

Note: Since alcohol infusions are generally only used in veterinary medicine for the treatment of ethylene glycol/methanol toxicity and obtaining medical or laboratory grade alcohol or pharmaceutical grade products can be very difficult in an emergency, veterinarians have often had to improvise. One method that has been successful, albeit not pharmaceutically elegant, is to use commercially available vodka (40%, 80 proof) diluted in an appropriate IV solution.

- To make a 20% ethanol solution using 80 proof (40%) vodka: dilute with an equal volume (500 mL with 500 mL) of IV fluids (e.g.; LRS, Normosol-R).
- To make a 5% solution using 80 proof (40%) vodka: add 125 mL of 80 proof (40%) vodka to 875 mL of IV fluid (remove about 125 mL of fluid from the bag).

100 proof (50%) vodka or 190 proof (95%) grain alcohol ("Everclear") can also be used. Dilute as appropriate to make a 5–20% solution. Regardless of the product used, it is recommended that an in-line filter be used for the IV.

Dosage Forms/Regulatory Status

For information on obtaining tax-free alcohol for medicinal purposes, contact a regional office of the Bureau of Alcohol, Tobacco, and Firearms.

ETIDRONATE DISODIUM

(e-*ti*-droe-nate) Didronel®

ORAL BISPHOSPHONATE BONE RESORPTION INHIBITOR

Prescriber Highlights

- Bisphosphonate that reduces calcium resorption from bone; used primarily to treat hypercalcemia associated with malignancy
- Contraindications: Treatment of hypercalcemia in patients with severe renal function impairment
- Caution in patients with bone fractures, enterocolitis, cardiac failure, or moderate renal function impairment
- Adverse Effects: Potentially, diarrhea, nausea, or bone pain/tenderness
- Do not confuse etidronate with etretinate or etomidate
- Expense may be an issue

Uses/Indications

Etidronate is a first generation bisphosphonate that may be useful for the treatment of severe hypercalcemia associated with neoplastic disease. Its use in human medicine has been largely replaced with newer, more potent bisphosphonates that can be dosed less often or have fewer adverse effects. Etidronate is also indicated in humans for the treatment of Paget's disease and heterotopic ossification (e.g., after total hip replacement).

Pharmacology/Actions

Etidronate's primary site of action is bone. It reduces normal and abnormal bone resorption. This effect can reduce hypercalcemia associated with malignant neoplasms. Etidronate can also increase serum phosphate concentrations, presumably by increasing the renal tubular reabsorption of phosphate. Some early studies in lab animals suggest that etidronate may inhibit the formation of bone metastases with some tumor types.

Pharmacokinetics

Oral absorption is poor and dose dependent. As little as 1% of a dose (smaller doses) may be absorbed; with higher doses, 6–10% may be absorbed. After oral dosing, the drug is rapidly cleared from blood and 50% of the drug absorbed goes into bone. At usual doses, it appears that etidronate does not cross the placenta. Duration of effect may be very prolonged. In humans, effects have persisted for up to one year after discontinuation in patients with Paget's disease. Effects for hypercalcemia may last for 11 days. Absorbed etidronate is excreted unchanged by the kidneys. Approximately 50% of the absorbed dose is excreted within 24 hours; the remainder is chemisorbed to bone and then slowly eliminated.

Contraindications/Precautions/Warnings

Etidronate is considered contraindicated for the treatment of hypercalcemia in patients with renal function impairment (serum creatinines >5 mg/dL). Risk vs. benefit should be carefully considered in patients with bone fractures (delays healing), enterocolitis (higher risk of diarrhea), cardiac failure (especially with parenteral etidronate as patients may not tolerate the extra fluid load), or those with renal function impairment (serum creatinines 2.5–5 mg/dL).

Do not confuse etidronate with etretinate or etomidate.

Adverse Effects

Adverse effects are not well described in small animals. In humans, diarrhea, nausea (with higher oral doses), and bone pain/tenderness are most the likely adverse effects reported. Increases in serum creatinine are possible.

Reproductive/Nursing Safety

Etidronate's safety during pregnancy has not been established. Rabbits given oral doses 5X those recommended in humans, demonstrated no overt problems with offspring. Rats, given very large doses IV, showed skeletal malformations. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is unknown if the drug enters milk.

Overdosage/Acute Toxicity

Very little information is available at this time. Overdoses may result in hypocalcemia (ECG changes may occur), bleeding problems (secondary to rapid chelation of calcium) and proximal renal tubule damage.

Use standard gut emptying protocols after oral ingestion when warranted. IV calcium administration (e.g., calcium gluconate) may be used to reverse hypocalcemia. Intensive monitoring is suggested.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving etidronate and may be of significance in veterinary patients:

- **ANTACIDS, DIARY PRODUCTS, MINERAL SUPPLEMENTS**, and medications containing **iron, magnesium, calcium or aluminum**: Absorption of oral etidronate may be inhibited; separate etidronate doses from these substances by at least two hours.

Laboratory Considerations

- Etidronate may interfere with bone uptake of technetium Tc 99m medronate or technetium Tc 99m oxidronate

Doses

■ DOGS:

For severe hypercalcemia associated with neoplastic disease:

- a) 5 mg/kg/day PO (Papich 1992); (Gaschen 2000)
- b) 5–20 mg/kg/day PO (Ward 1999)
- c) 5–15 mg/kg daily to twice daily PO; for moderate to severe hypercalcemia (Chew, Schenck et al. 2003)

■ CATS:

For severe hypercalcemia associated with neoplastic disease:

- a) 10 mg/kg/day PO (Papich 1992)
- b) 5–20 mg/kg/day PO (Ward 1999)

Monitoring

- Serum calcium
- Serum protein

Client Information

- Recommended to give dose to animal that has an empty stomach.
- If anorexia or vomiting occur, notify veterinarian.

Chemistry/Synonyms

An analog of pyrophosphate, etidronate disodium (also known as EHDP, Na₂EHDP, or sodium etidronate) is a biphosphonate agent that occurs as a white powder and is freely soluble in water. Unlike

pyrophosphate, etidronate is resistant to enzymatic degradation in the gut.

Etidronate disodium may also be known as: EHDP, disodium etidronate, etidronate disodium, *Anfozan*®, *Bonemass*®, *Didronate*®, *Didronel*®, *Difosfen*®, *Diphos*®, *Dralen*®, *Dronate-OS*®, *Etidrate*®, *Etidron*®, *Etiplus*®, *Feminoflex*®, *Ostedron*®, *Osteodidronel*, *Osteum*®, *Ostogene*®, *Ostopor*®, *Somaflex*®, and *Sviroxit*®.

Storage/Stability

Store tablets in tight containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Etidronate Disodium Tablets: 200 mg, & 400 mg; *DidroneI*® (Procter & Gamble Pharm.); Etidronate Disodium (Genpharm); (Rx)

ETODOLAC

(ee-toe-doe-lak) EtoGesic®, Lodine®

NON-STEROIDAL ANTIINFLAMMATORY AGENT

Prescriber Highlights

- NSAID (oral) used in dogs, relatively few adverse effects & labeled for once daily
- Contraindications: Hypersensitivity
- Caution: Patients with preexisting or occult GI, hepatic, renal, cardiovascular, or hematologic abnormalities
- Safe use not established for dogs less than 12 months of age or in breeding, pregnant, or lactating dogs
- Adverse Effects: Vomiting, diarrhea, lethargy, hypoproteinemia; keratoconjunctivitis sicca possible
- Drug interactions

Uses/Indications

Etodolac is labeled for the management of pain and inflammation associated with osteoarthritis in dogs. It may find uses, however, for a variety of conditions where pain and/or inflammation should be treated.

Pharmacology/Actions

Like other NSAIDs, etodolac has analgesic, antiinflammatory, and antipyretic activity. Etodolac appears to be more selective for inhibition of cyclooxygenase-2 than cyclooxygenase-1. This means that the drug should possess greater inhibition of the prostaglandins involved with pain and inflammation than those involved with cytoprotection of the GI tract and renal tissue. Etodolac is also thought to inhibit macrophage chemotaxis, which may explain some of its antiinflammatory activity.

In horses, etodolac does not exhibit much COX-2 selectivity.

Pharmacokinetics

The S(+) enantiomer is thought to provide the bulk of the pharmacologic activity, but the drug is supplied as a racemic mixture. Pharmacokinetic studies that measure both forms as one are not very relevant clinically. After oral administration to healthy dogs, etodolac is rapidly and nearly completely absorbed. The presence of food may alter the rate, but not the extent, of absorption. Peak serum levels occur about 2 hours post dosing. Etodolac is highly

bound to serum proteins. The drug is primarily excreted via the bile into the feces. Glucuronide conjugates have been detected in the bile but not the urine. Elimination half-life in dogs varies depending whether food is present in the gut, which may affect the rate of enterohepatic circulation of the drug. These values range from about 8 hours (fasted) to 12 hours (non-fasted).

In horses, etodolac has an oral bioavailability of about 77%. After IV dosing, volume of distribution was 0.29 L/kg and the clearance was 235 mL/hr/kg. Elimination half-life (after IV dosing) was approximately 2.5–3 hours.

Contraindications/Precautions/Warnings

Etodolac is contraindicated in dogs previously found to be hypersensitive to it. It should be used with caution in dogs with preexisting or occult GI, hepatic, cardiovascular, or hematologic abnormalities as NSAIDs may exacerbate these conditions. Patients may be more susceptible to renal injury from etodolac if they are dehydrated, on diuretics, or have preexisting renal, hepatic, or cardiovascular dysfunction.

Safety of etodolac has not been established in dogs less than 12 months of age.

Adverse Effects

In clinical field studies, etodolac's primary adverse effect was vomiting/regurgitation, reported in about 5% of dogs tested. Diarrhea, lethargy, and hypoproteinemia were also reported in a small number of dogs. Urticaria, behavioral changes, and inappetence were reported in less than 1% of dogs treated. It must be remembered, however, that as the drug is used in many more dogs for significant periods, additional adverse effects may surface.

Etodolac may decrease total serum T4 in some dogs. Clinical significance is unclear.

Etodolac appears to have less impact on clotting times than other canine-approved NSAIDs.

Cases have been reported of dogs developing keratoconjunctivitis sicca (KCS) after receiving etodolac treatment. Incidence rate is unknown at this time.

Potentially, hepatotoxicity and/or nephrotoxicity are possible.

The manufacturer warns to terminate therapy if inappetence, vomiting, fecal abnormalities, or anemia are observed.

Reproductive/Nursing Safety

Safe use has not been established in breeding, pregnant, or lactating dogs; use only when the benefits clearly outweigh the potential risks in these animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Most NSAIDs are excreted in milk; use with caution.

Overdosage/Acute Toxicity

Limited information is available, but in a safety study where dogs were given 40 mg/kg/day (2.7X) GI ulcers, weight loss, emesis and local occult blood were noted. Doses of 80 mg/kg/day (5.3X), caused 6 of 8 dogs to either die or become moribund secondary to GI ulceration. It should be noted that these were not single dose overdoses. However, they demonstrate that there is a relatively narrow therapeutic window for the drug in dogs and that doses should be carefully determined (*i.e.*, do not confuse mg/kg dosages with mg/lb).

There were 34 exposures to etodolac reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 24 cases were dogs that showed no clinical signs and 10 were cats with 2 showing clinical signs. Common

findings in these cats are recorded in decreasing frequency including acute renal failure, anorexia, collapse, hyperkalemia and hypersalivation.

This medication is a NSAID. As with any NSAID, overdosage can lead to gastrointestinal and renal effects. Decontamination with emetics and/or activated charcoal is appropriate. For doses where GI effects are expected, the use of gastrointestinal protectants is warranted. If renal effects are also expected, fluid diuresis is warranted.

Drug Interactions

Note: Although the manufacturer does not list any specific drug interactions in the package insert, it does caution to avoid or closely monitor etodolac's use with other drugs, especially those that are also highly protein bound. It also recommends close monitoring, or to **avoid using etodolac with any other ulcerogenic drugs** (*e.g.*, **corticosteroids, other NSAIDs**).

The following drug interactions have either been reported or are theoretical in humans or animals receiving etodolac and may be of significance in veterinary patients:

- **ACE INHIBITORS** (*enalapril, benazepril, etc.*): Etodolac may reduce the antihypertensive effects of ACE inhibitors
- **ASPIRIN**: When aspirin is used concurrently with etodolac, plasma levels of etodolac could decrease and an increased likelihood of GI adverse effects (blood loss) could occur; concomitant administration of aspirin with etodolac cannot be recommended
- **CYCLOSPORINE**: Etodolac may increase cyclosporine blood levels and increase the risk for nephrotoxicity
- **DIGOXIN**: Etodolac may increase serum levels of digoxin. Use with caution in patients with severe cardiac failure
- **FUROSEMIDE & OTHER DIURETICS**: Etodolac may reduce the saluretic and diuretic effects of furosemide
- **METHOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with caution
- **NEPHROTOXIC AGENTS** (*e.g.*, **amphotericin B, aminoglycosides, cisplatin, etc.): Potential for increased risk of nephrotoxicity if used with NSAIDs**
- **PROBENECID**: May cause a significant increase in serum levels and half-life of etodolac
- **WARFARIN**: Etodolac may increase the risk for bleeding

Laboratory Considerations

- Etodolac may cause false-positive determinations of **urine bilirubin**.
- Etodolac therapy may alter **thyroid function tests** and their interpretation; falsely low values may occur in dogs receiving etodolac.

Doses

■ DOGS:

- a) For treatment of pain and inflammation associated with osteoarthritis: 10–15 mg/kg PO once daily. Dogs less than 5 kg cannot be accurately dosed with *EtoGesic*®. Adjust dose to obtain satisfactory response, but do not exceed 15 mg/kg. For long-term therapy, reduce dose level to minimum effective dosage. (Package Insert; *EtoGesic*®—Fort Dodge)
- b) 5–15 mg/kg PO once daily (Hardie 2000)

Monitoring

- Baseline (especially in geriatric dogs or dogs with chronic diseases or those where prolonged treatment is likely): physical exam, CBC, Serum chemistry panel (including liver and renal function tests), UA. It is recommended to reassess liver enzymes at one

week of therapy. Should elevation occur, recommend discontinuing the drug

- Clinical efficacy
- Signs of potential adverse reactions: inappetence, diarrhea, mucoid feces, vomiting, melena, polyuria/polydipsia, anemia, jaundice, lethargy, tear production, behavior changes, ataxia, or seizures
- Chronic therapy: Consider repeating CBC, UA, and serum chemistries on an ongoing basis.

Client information

- Give the client written information on the proper use and monitoring for etodolac

Chemistry/Synonyms

An indole acetic acid derivative non-steroidal antiinflammatory agent (NSAID), etodolac occurs as a white, crystalline compound that is insoluble in water, but soluble in alcohol or DMSO. Etodolac has a chirally active center with a corresponding S (+) enantiomer and an R (-) enantiomer. The commercially available product is supplied as a racemic mixture of the forms.

Etodolac may also be known as: AY-24236, etodolacum, etodolic acid, *Acudor*®, *Articulan*®, *Dualgan*®, *Eccoxolac*®, *Edolan*®, *Elderin*®, *EtoGesic*®, *Etonox*®, *Etopan*®, *Flancox*®, *Hypen*®, *Lodot*®, *Lonine*®, *Metazin*®, *Sodolac*®, *Todolac*®, *Ultradol*®, and *Zedolac*®.

Storage/Stability

The commercially available veterinary tablets should be stored at controlled room temperature (15–30°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Etodolac Scored Tablets: 150 mg and 300 mg in bottles of 30 and 90; *EtoGesic*® (Fort Dodge); (Rx). Approved for use in dogs. Do not use in cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Etodolac Tablets: 200 mg, 300 mg, 400 mg, 500 mg tablets and 400 mg, 500 mg and 600 mg extended release tablets; generic; (Rx)

ETOMIDATE

(ee-toe-*mi*-date) Amidate®

INJECTABLE ANESTHETIC

Prescriber Highlights

- ▶ Injectable non-barbiturate anesthetic agent that may be useful as an alternative to thiopental or propofol for induction, particularly in patients with preexisting cardiac dysfunction, head trauma, or that are critically ill
- ▶ Not a controlled substance
- ▶ Relatively expensive, especially in large dogs

Uses/Indications

Etomidate may be useful as an alternative to thiopental or propofol for anesthetic induction in small animals, particularly in patients with preexisting cardiac dysfunction, head trauma, or that are critically ill.

Pharmacology/Actions

The exact mechanism of action of etomidate is not well defined. Etomidate causes minimal hemodynamic changes and little effect on the cardiovascular system when compared to other injectable anesthetic agents. At usual doses, etomidate has little effect on respiratory rate or rhythm. Etomidate decreases cerebral blood flow and oxygen consumption. It usually lowers intraocular pressure and causes slight decreases in intracranial pressure.

The reported therapeutic index (toxic dose/therapeutic dose) for etomidate is 16. Therapeutic indexes for propofol and thiopental are 3 and 5 respectively.

Pharmacokinetics

No specific information on the pharmacokinetics of etomidate in domesticated animals was located. In humans, after intravenous injection etomidate is rapidly distributed into the CNS and then rapidly cleared from the brain back into systemic tissues. Duration of hypnosis is short (3–5 minutes) and dependent upon dose. Recovery from anesthesia appears to be as fast as with thiopental, but slower than propofol. Etomidate is 75% bound to plasma proteins. The drug is rapidly metabolized in the liver primarily via hydrolysis or glucuronidation to inactive metabolites. The majority of the drug and metabolites are excreted into the urine with the remainder into the bile and feces. Elimination half-life ranges from 1.25–5 hours.

Contraindications/Precautions/Warnings

Etomidate is contraindicated in patients known to be hypersensitive to it.

Etomidate can inhibit adrenocortical function; it should not be used for purposes other than induction, and with caution in patients whose adrenocortical function is impaired. Exogenous glucocorticoid administration should be considered in severely compromised animals.

Etomidate does not provide any analgesia.

Limited studies in patients with impaired hepatic or renal function have shown that elimination half-lives may be significantly increased in these patients.

Adverse Effects

Common adverse effects include pain at intravenous injection site, skeletal muscle movements (myoclonus), eye movements, and post-operative retching. Preanesthetic medications and a benzodiazepine (diazepam, midazolam) just prior to etomidate can minimize these effects.

Some hemolysis may occur due to the propylene glycol content of the injection. Some anesthesiologists recommend injecting etomidate into a running IV line to decrease the pain associated with injection and, potentially, reduce hemolysis.

While etomidate causes minimal cardiopulmonary depression, a brief period of hypoventilation and decreased arterial blood pressure can occur after administration.

Apnea, laryngospasm, hiccups, hyperventilation, hypoventilation, hypertension, hypotension, lactic acidosis, arrhythmias, and postoperative vomiting have all been reported in human patients that have received the drug. Seizures have been reported in a few human patients receiving etomidate; this adverse effect may be reduced if an opiate premed is first administered.

Reproductive/Nursing Safety

In humans, the FDA categorizes etomidate as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*).

Etomidate has caused embryocidal effects in rats and maternal toxicity in rabbits and rats.

Some etomidate is excreted into maternal milk; use with caution in nursing patients.

Overdosage/Acute Toxicity

Acute overdoses would be expected to cause enhanced pharmacologic effects of the drug. Treatment would be supportive (*i.e.*, mechanical ventilation), until the effects of the medication are diminished.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving etomidate and may be of significance in veterinary patients:

- **CNS/RESPIRATORY DEPRESSANTS** (*e.g.*, barbiturates, opiates, anesthetics, etc.): Additive pharmacological effects can occur if etomidate is used concurrently with other drugs that can depress CNS or respiratory function
- **VERAPAMIL**: Has been associated with potentiating the anesthetic and respiratory depressant effects of etomidate

Laboratory Considerations

No specific laboratory interactions or considerations located.

Doses

■ DOGS & CATS:

- a) As an induction agent: etomidate 1 mg/kg IV plus diazepam 0.5 mg/kg IV (Cornell 2004)
- b) As an induction agent: 1–2 mg/kg rapidly IV (Heath 2003)
- c) As an induction agent: 0.5–2 mg/kg IV. Pre-medication is highly recommended to reduce incidence of side effects (myoclonus, vomiting). Alternatively or additionally, etomidate may be given with a benzodiazepine. Because of its effects on cortisol, administration of a physiologic dose of dexamethasone or another short-acting glucocorticoid prior to etomidate is suggested. (Mama 2002a)

■ FERRETS:

- a) As an induction agent in the cardiovascular unstable patient: etomidate 1–2 mg/kg IV after diazepam (0.5 mg/kg IV) (Lichtenberger 2006a)

■ SMALL MAMMALS:

- a) Rabbits: As an induction agent in the cardiovascular unstable patient: etomidate 1–2 mg/kg IV after diazepam (0.5 mg/kg IV) (Lichtenberger 2006a)

Monitoring

As per any anesthetic agent:

- Level of consciousness
- Respiration rate and depth
- Cardiovascular function

Client Information

- Etomidate is a potent sedative-hypnotic that should only be used by professionals in a setting where adequate patient monitoring is available.

Chemistry/Synonyms

An injectable, carboxylic imidazole anesthetic, etomidate occurs as a white or almost white powder. It is very slightly soluble in water and freely soluble in alcohol. The commercially available injection has a pH of 8.1, contains 35% propylene glycol, and is hyperosmolar (4640 mosm/l).

Etomidate may also be known as: R-16659, *Amidate*®, *Hypnomidate*®, *Radenarcon*®, or *Sibul*®.

Storage/Stability

Unless otherwise labeled, store etomidate injection at room temperature and protect from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Etomidate Injection: 2 mg/mL in 10 mL, 20 mL amps and 20 mL *Abboject* syringes; *Amidate*® (Hospira); (Rx)

Etretinate—see **Acitretin**

EUTHANASIA AGENTS WITH PENTOBARBITAL

(yoo-thon-ayzh-ya; pen-toe-barb-i-tal)

For therapeutic uses (other than euthanasia) of pentobarbital, see the main pentobarbital monograph for this agent. The sections on chemistry, storage, pharmacokinetics, overdosage, drug interactions, and monitoring parameters can be found in the main pentobarbital monograph.

Prescriber Highlights

- Used for humane euthanasia for animals not to be used for food
- Store so that it will not be confused with therapeutic agents; keep out of reach of children
- Use care in handling filled syringes & dispose of used injection equipment properly
- Avoid any contact with open wounds or accidental injection
- Tranquilizing agent may be necessary when the animal is in pain or agitated
- Renderers may not accept carcasses euthanized with pentobarbital

Uses/Indications

For rapid, humane euthanasia in animals not intended for food purposes. Individual products may be approved for use in specific species.

“The advantages of using barbiturates for euthanasia in small animals far outweigh the disadvantages. Intravenous injection of a barbituric acid derivative is the preferred method for euthanasia of dogs, cats, other small animals, and horses. Intraperitoneal injection may be used in situations when an intravenous injection would be distressful or even dangerous. Intracardiac injection must only be used if the animal is heavily sedated, unconscious, or anesthetized.” (AVMA Guidelines on Euthanasia, 2007)

Pharmacology/Actions

Pentobarbital causes death by severely depressing the medullary respiratory and vasomotor centers when administered at high doses. Cardiac activity may persist for several minutes following administration.

Phenytoin is added to *Beuthanasia*®-D Special (Schering) for its added cardiac depressant effects and to denature the compounds from a Class-II controlled substance to Class-III drugs.

Contraindications/Precautions/Warnings

Must not be used in animals to be used for food purposes (human or animal consumption). Should be stored in such a manner that these products will not be confused with therapeutic agents. Extreme care in handling filled syringes and proper disposal of used injection equipment must be undertaken. Avoid any contact with open wounds or accidental injection. Keep out of reach of children.

Prior use of a tranquilizing agent may be necessary when the animal is in pain or agitated.

Adverse Effects

Minor muscle twitching may occur after injection. Death may be delayed or not accomplished if injection given perivascularly.

Doses

Because different products have different concentrations, please refer to the information provided with the product in use.

■ DOGS:

- Pentobarbital sodium (as a single agent): Approximately 120 mg/kg for the first 4.5 kg of body weight, and 60 mg/kg for every 4.5 kg of body weight thereafter. Preferably administer IV.
- Pentobarbital sodium with phenytoin (*Beuthanasia*®-D Special): 1 mL for each 4.5 kg of body weight.

■ CATS:

- Pentobarbital sodium (as a single agent): Approximately 120 mg/kg for the first 4.5 kg of body weight, and 60 mg/kg for every 4.5 kg of body weight thereafter. Administer IV.
- Pentobarbital sodium with phenytoin (*Beuthanasia*®-D Special): 1 mL for each 4.5 kg of body weight (not approved for use in this species)

■ LARGE ANIMALS:

Note: must not be used in animals to be consumed by either humans or other animals.

- Depending on product concentration, most animals require 10–15 mL per 100 pounds of body weight.

Monitoring

- Respiratory rate
- Cardiac rate
- Corneal reflex

Client Information

- Must be administered by an individual familiar with its use.
- Animals must be restrained during administration.
- Inform clients observing euthanasia that animal may give a terminal gasp after becoming unconscious.

Dosage Forms/Regulatory Status

See other pentobarbital dosage forms under the main pentobarbital monograph for lower concentration products that are used therapeutically.

VETERINARY-LABELED PRODUCTS:

Pentobarbital Sodium 390 mg/mL & Phenytoin Sodium 50 mg/mL for Injection (Euthanasia) in 100 mL vials; *Beuthanasia*®-D Special (Schering-Plough); *Euthasol*® (Virbac); *Euthanasia-III*® Solution (Med-Pharmex); *Somnasol*® (Butler); (Rx, C-III). Approved for use in dogs.

Pentobarbital Sodium Powder:

392 mg/mL when constituted with 250 mL of water. *Fatal-Plus*® Powder (Vortech), *Pentadol*® Powder (Virbac); (Rx, C-II) Approved for use in animals regardless of species.

Pentobarbital Sodium for Injection (Euthanasia):

260 mg/mL: *Sleepaway*® (Fort Dodge) 26%: in 100 mL bottles; (Rx, C-II). Approved for use in dogs and cats.

324 mg/mL: *SP5*® (Vedco) in 100 mL vials; (Rx, C-II). Approved for use in dogs and cats.

389 mg/mL: *Socumb-6gr*® (Butler), *Somlethol*® (Webster), *SP6*® (Vedco); 100 mL & 250 mL vials; (Rx, C-II). Approved for use in dogs and cats.

390 mg/mL: *Fatal-Plus*® Solution (Vortech); in 250 mL vials (Rx, C-II). Approved for use in animals regardless of species.

HUMAN-LABELED PRODUCTS: None

FAMCICLOVIR

(fam-sye-klow-veer) Famvir®

ANTIVIRAL (HERPES)

Prescriber Highlights

- May be effective in treating feline herpes (FHV-1) infections
- Limited experience and information available in using this medication in cats
- Appears to be well tolerated when used short-term (2–3 weeks)

Uses/Indications

Famciclovir may be of benefit in treating feline herpes infections.

Pharmacology/Actions

Famciclovir is rapidly converted *in vivo* to penciclovir. In cells infected with susceptible Herpes virus or varicella zoster virus, viral thymidine kinase phosphorylates penciclovir to penciclovir monophosphate. Cellular kinases further convert this compound to penciclovir triphosphate which inhibits herpes virus DNA polymerase via competition with deoxyguanosine triphosphate, thereby selectively inhibiting herpes viral DNA synthesis.

Viral resistance can occur by mutation.

Pharmacokinetics

In cats, after oral administration of famciclovir (62.5 mg), penciclovir peak levels were less than the *in vitro* inhibitory concentration 50 (IC-50) for FHV-1. It is postulated that cats either absorb famciclovir or convert it to penciclovir poorly and that they will likely require higher doses than other species. (Thomasy, Maggs et al. 2006)

In humans, famciclovir is well absorbed after oral administration, but undergoes extensive first pass metabolism (not by CYP enzymes). Food can decrease peak levels, but does not significantly impact clinical efficacy. Penciclovir (active metabolite) is only marginally bound to plasma proteins. In humans, penciclovir elimination half-life is about 2–3 hours; excretion is primarily via renal mechanisms. Intracellular half-lives of penciclovir in infected cells are significantly longer.

Contraindications/Precautions/Warnings

Famciclovir is contraindicated in patients known to be hypersensitive to it or penciclovir.

It should be used with caution (and dosage adjustment) in patients with renal dysfunction. In humans patients with CrCl <40 mL/min, dosage adjustments are recommended.

Adverse Effects

Adverse effects in cats are not well documented, but the drug appears to be tolerated quite well when used for up to 3 weeks.

In humans, famciclovir can cause nausea, vomiting, diarrhea, and headache. Neutropenia has been reported and renal failure can occur, particularly when doses are not adjusted in patients with renal dysfunction.

Reproductive/Nursing Safety

In laboratory animals, doses of up to 1,000 mg/kg/day did not cause any observed effects on developing embryos or fetuses. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Famciclovir (as penciclovir) is excreted in the milk of rats. It is unclear if there is any clinical significance for nursing offspring.

Overdosage/Acute Toxicity

Little information is available. Supportive treatment has been recommended. Penciclovir can be removed by hemodialysis.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving famciclovir and may be of significance in veterinary patients:

- **PROBENECID:** Can reduce the amount of penciclovir excreted by the kidneys; increase penciclovir plasma levels can occur

Laboratory Considerations

No concerns noted

Doses■ **CATS:**

- For feline herpes virus (FHV-1):
 - For adjunctive treatment of FHV-1 rhinotracheitis: 31.25 mg (¼ of one 125 mg tablet) PO q12h for 14 days. Has not been evaluated for long-term therapy. (Lappin 2007)
 - For chronic, recurrent and/or severe herpes viral infection: Dose range is variable! Kittens: ⅛th of one 125 mg tablet PO once daily (q24h) for 2 weeks; adult cats: ¼ of one 250 mg tablet once daily (q24h) for 3 weeks. (Diehl 2007b)
 - ¼ of one 125 mg tablet PO twice daily (q12h) for 10–14 days; may continue once daily for up to 30 days. (Ramsey 2006)
 - For adjunctive treatment (with interferon and lysine) of herpes virus-associated ulcerative facial dermatitis & stomatitis: 125 mg PO q12h. (Hillier 2006c)

Monitoring

- Clinical efficacy
- Adverse effects (most likely GI)
- Consider occasional CBC's and creatinine to monitor for neutropenia or renal dysfunction if using the drug chronically

Client Information

- May be administered with food
- There is limited experience with this drug in cats, report any unusual effects to the veterinarian

Chemistry/Synonyms

A prodrug, famciclovir is a purine-derived, synthetic, acyclic purine nucleoside analog.

Famciclovir may also be known as AV 42810, BRL 42810, famciclovirum, or by the trade name *Famvir*®.

Storage/Stability

Famciclovir tablets should be stored at room temperature (15–30°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Famciclovir Tablets (film-coated) 125 mg, 250 mg, & 500 mg: *Famvir*® (Novartis); generic; (Rx)

FAMOTIDINE

(fa-moe-ti-deen) Pepcid®

H2-RECEPTOR ANTAGONIST**Prescriber Highlights**

- H₂-receptor antagonist used to reduce GI acid production
- Longer duration of action & fewer drug interactions than cimetidine
- Contraindications: Hypersensitivity to H₂ blockers
- Caution: Patients with cardiac disease, significantly impaired hepatic or renal function; (consider dosage reduction)
- Adverse Effects: Too rapid IV infusion may cause bradycardia. Potentially: GI effects, headache, or dry mouth or skin, intravascular hemolysis when given IV to cats

Uses/Indications

In veterinary medicine, famotidine may be useful for the treatment and/or prophylaxis of gastric, abomasal and duodenal ulcers, uremic gastritis, stress-related or drug-induced erosive gastritis, esophagitis, duodenal gastric reflux, and esophageal reflux.

Famotidine has fewer drug interactions and activity may persist longer than cimetidine.

Pharmacology/Actions

At the H₂ receptors of the parietal cells, famotidine competitively inhibits histamine, thereby reducing gastric acid output both during basal conditions and when stimulated by food, pentagastrin, histamine or insulin. Gastric emptying time, pancreatic or biliary secretion, and lower esophageal pressures are not altered by famotidine. By decreasing the amount of gastric juice produced, H₂-blockers also decreases the amount of pepsin secreted.

Pharmacokinetics

Famotidine is not completely absorbed after oral administration, but undergoes only minimal first-pass metabolism. In humans, systemic bioavailability is about 40–50%. Distribution characteristics are not well described. In rats, the drug concentrates in the liver,

pancreas, kidney and submandibular gland. Only about 15–20% is bound to plasma proteins. In rats, the drug does not cross the blood brain barrier or the placenta. It is distributed into milk. When the drug is administered orally, about $\frac{1}{3}$ is excreted unchanged in the urine and the remainder primarily metabolized in the liver and then excreted in the urine. After intravenous dosing, about $\frac{2}{3}$'s of a dose is excreted unchanged.

The pharmacokinetics of famotidine, ranitidine, and cimetidine have been investigated in horses. (Duran and Ravis 1993) After a single IV dosage, elimination half-lives of cimetidine, ranitidine, and famotidine all were in the 2–3 hour range and were not significantly different. Of the three drugs tested, famotidine had a larger volume of distribution (4.28 L/kg) than either cimetidine (1.14 L/kg) or ranitidine (2.04 L/kg). Bioavailability of each of the drugs was low; famotidine (13%), ranitidine (13.5%) and cimetidine (30%).

Contraindications/Precautions/Warnings

Famotidine is contraindicated in patients with known hypersensitivity to the drug.

Famotidine should be used cautiously in geriatric patients and patients with significantly impaired hepatic or renal function. Consider dosage reduction in patients with significant renal dysfunction. Famotidine may have negative inotropic effects and have some cardioarrhythmogenic properties. Use with caution in patients with cardiac disease.

Adverse Effects

Too rapid IV infusion may cause bradycardia. Other H_2 -blockers have been demonstrated to be relatively safe and exhibit minimal adverse effects. Potential adverse effects (documented in humans) that could be seen include GI effects (anorexia, vomiting, diarrhea), headache, or dry mouth or skin. Rarely, agranulocytosis may develop particularly when used concomitantly with other drugs that can cause bone marrow depression.

While some clinicians routinely use famotidine intravenously in cats, there have been anecdotal reports of famotidine causing intravascular hemolysis when given intravenously to cats. It is believed this is probably an idiosyncratic reaction that occurs in a small percentage of cats treated.

Reproductive/Nursing Safety

In lab animal studies, famotidine demonstrated no detectable harm to offspring. Large doses could affect the mother's food intake and weight gain during pregnancy that could indirectly be harmful. Use in pregnancy when potential benefits outweigh the risks. In rats, nursing from mothers receiving very high doses of famotidine, transient decreases in weight gain occurred. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Famotidine is excreted in the milk of rats. It is unclear if there is any clinical significance for nursing offspring with H_2 -blockers in milk.

Overdosage/Acute Toxicity

The minimum acute lethal dose in dogs is reported to be >2 grams/kg for oral doses and approximately 300 mg/kg for intravenous doses. IV doses in dogs ranging from 5–200 mg/kg IV caused: vomiting, restlessness, mucous membrane pallor and redness of the mouth and ears. Higher doses caused hypotension, tachycardia and collapse.

Because of this wide margin of safety associated with the drug,

most overdoses should require only monitoring. In massive oral overdoses, gut-emptying protocols should be considered and supportive therapy initiated when warranted.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving famotidine and may be of significance in veterinary patients:

■ **AZOLE ANTIFUNGALS (ketoconazole, itraconazole, fluconazole):** By raising gastric pH, famotidine may decrease the absorption of these agents; if both drugs are required, administer the azole one hour prior to famotidine

■ **CEFPODOXIME, CEFUROXIME:** Famotidine may decrease the absorption of these cephalosporins; taking with food may alleviate this effect

■ **IRON SALTS (ORAL):** Famotidine may decrease the absorption of oral iron; administer iron at least one hour prior to famotidine

Unlike cimetidine or ranitidine, famotidine does not appear to inhibit hepatic cytochrome P-450 enzyme systems and dosage adjustments of other drugs (e.g., warfarin, theophylline, diazepam, procainamide, phenytoin) that are metabolized by this metabolic pathway should usually not be required.

Laboratory Considerations

■ Histamine₂-blockers may antagonize the effects of **histamine** and **pentagastrin** in the evaluation gastric acid secretion.

■ After using allergen extract **skin tests**, histamine₂ antagonists may inhibit histamine responses. It is recommended that histamine₂ blockers be discontinued at least 24 hours before performing either of these tests.

Doses

■ DOGS:

To reduce gastric acid production:

- 0.5 mg/kg PO, SC, IM, IV q12–24 hours (Matz 1995)
- 0.5–1 mg/kg PO or IV once or twice daily (Johnson, Sherdling et al. 1994)
- 0.1–0.2 mg/kg PO q8h (Zerbe and Washabau 2000)
- 0.55–1.1 mg/kg PO q24h (or every 12 hours if there is severe esophagitis) for 2–3 weeks in dogs with acute reflex esophagitis (Tams 2003a)
- For adjunctive treatment (to prevent/treat gastric ulcers) of mast cell tumors: 0.5 mg/kg once daily (route not specified). (Garrett 2006)
- For adjunctive treatment of GI effects (anorexia, nausea, vomiting) associated with chronic kidney disease: 0.5 mg/kg PO once daily (q24h) Effective evidence grade: 3. (Polzin 2005b)

■ CATS:

Note: See the warning (in the adverse effects section) about IV use in cats.

To reduce gastric acid production:

- 0.5 mg/kg PO, SC, IM, IV q12–24 hours (Matz 1995)
- 0.5 mg/kg PO or parenterally once daily (Trepanier 1999)
- 0.55–1.1 mg/kg PO q24h (or every 12 hours if there is severe esophagitis) for 2–3 weeks in cats with acute reflex esophagitis (Tams 2003a)

For adjunctive treatment of GI effects (anorexia, nausea, vomiting) associated with chronic progressive renal disease:

- 1 mg/kg PO once daily (q24h) (Wolf 2006b)

b) 0.5–1 mg/kg PO once or twice daily (q12–24h) (Zoran 2006a)

■ **FERRETS:**

- a) For stress induced ulcers: 0.25–0.5 mg/kg PO, IV once daily (Williams 2000)
- b) In combination with antibiotics for *Helicobacter* treatment: 0.25–0.5 mg/kg PO, IV q24h (Fisher 2005)

■ **SMALL MAMMALS:**

Rabbits: For stress induced ulcer prevention once critically ill animal has stabilized:

- a) 1 mg/kg IV once daily (q24h) (Johnston 2006)

■ **HORSES: (Note: ARCI UCGFS Class 5 Drug)**

As an adjunct in ulcer treatment:

- a) IV doses: 0.23 mg/kg, IV q8h or 0.35 mg/kg IV q12h.
Oral doses: 1.88 mg/kg, PO q8h or 2.8 mg/kg PO q12h (Duran and Ravis 1993)

Monitoring

- Clinical efficacy (dependent on reason for use); monitored by decrease in symptomatology, endoscopic examination, blood in feces, etc.
- Adverse effects, if noted

Client Information

- To maximize the benefit of this medication, it must be administered as prescribed by the veterinarian
- Clinical signs may reoccur if dosages are missed

Chemistry/Synonyms

An H₂-receptor antagonist, famotidine occurs as a white to pale yellow, crystalline powder. It is odorless, but has a bitter taste. 740 micrograms are soluble in one mL of water.

Famotidine may also be known as: famotidinum, L-643341, MK-208, and YM-11170; many trade names are available.

Storage/Stability/Compatibility

Tablets should be stored in well-closed, light-resistant containers at room temperature. Tablets are assigned an expiration date of 30 months after date of manufacture.

The powder for oral suspension should be stored in tight containers at temperatures less than 40°C. After reconstitution, the resultant suspension is stable for 30 days when stored at temperatures less than 30°C.; do not freeze.

Famotidine injection should be stored in the refrigerator (2–8°C). It is physically **compatible** with most commonly used IV infusion solutions and is stable for 48 hours at room temperature when diluted in these solutions.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Famotidine Tablets (plain, film-coated & orally disintegrating) & Gelscaps: 10 mg (regular & chewable), (OTC), 20 mg, & 40 mg; *Pepcid*®, *Pepcid AC*® *Maximum Strength* and *Pepcid RPD*® (Merck); (Rx); *Pepcid AC*® (J & J Merck); generic; (Rx & OTC))

Famotidine Powder for Oral Suspension: 8 mg/mL when reconstituted in 400 mg bottles; *Pepcid*® (Merck); (Rx)

Famotidine Injection: 10 mg/mL in 1 and 2 mL single dose vials and 4 mL, 20 mL and 50 mL multidose vials (may contain mannitol or benzyl alcohol); 20 mg/50 mL premixed (regular & preservative free) in 50 mL single-dose *Galaxy* containers; *Pepcid*® (Merck); generic; (Rx)

FATTY ACIDS, ESSENTIAL/ OMEGA FISH OIL/ VEGETABLE OIL

NUTRITIONAL

Prescriber Highlights

- Used for treatment of dogs with pruritus associated with atopy, idiopathic seborrhea; in cats for pruritus associated with miliary dermatitis & eosinophilic granuloma complex
- May also be useful in other species & for other disease states
- Safety in pregnancy not established; use caution in patients with coagulopathies
- Adverse Effects: High doses may cause GI distress; rarely some dogs may become lethargic or more pruritic

Uses/Indications

These products are generally indicated for the treatment of pruritus associated with atopy and idiopathic seborrhea. In cats, they can be used for treating pruritus in the adjunctive treatment of miliary dermatitis and eosinophilic granuloma complex. Fatty acids may improve coat quality and be helpful for adjunctive therapy for arthropathies such as hip dysplasia.

When used for pruritus, significant therapeutic effects may be noted in only 25–50% of patients treated and require 2–3 months of treatment before evaluating efficacy. Antihistamine and fatty acid therapy may be synergistic for treatment of pruritus.

Polyunsaturated fatty acids, particularly the omega-3's may prove to be useful for a variety of conditions, including renal failure, arthritis (both degenerative and autoimmune), cardiovascular disease (hypercoagulable states), and some neoplastic diseases. Further studies are required to document any clinical benefits for veterinary use, however.

Pharmacology/Actions

The exact pharmacologic actions of these products are not well described; particularly in light of the combination nature of the commercial products being marketed, it is difficult to ascertain which compounds may be responsible for their proposed efficacy. The particular therapeutic benefits and ratios of omega-3 versus omega-6 fatty acids are still being debated.

Fish oils affect arachidonic acid levels in plasma lipids and platelet membranes. They may affect production of inflammatory prostaglandins in the body, thereby reducing inflammation and pruritus. Linolenic or linoleic acids may be used as essential fatty acid sources which are necessary for normal skin and haircoats.

Contraindications/Precautions/Warnings

Because of potential effects on bleeding times, use with caution in patients with coagulation disorders or those receiving anticoagulant medications. Use with caution in patients with non-insulin dependent diabetes as omega-3 fatty acids have impaired insulin secretion with resultant increased glucose levels in humans with type-2

diabetes. Fatty acids should be used with caution in dogs that have had previous bouts with pancreatitis or protracted diarrhea.

Adverse Effects

At high dosages, GI disturbances (e.g., vomiting, diarrhea) may be seen. Rarely, some dogs become lethargic or more pruritic. In human patients, increased bleeding times and decreased platelet aggregation have been noted with use of fish oils; use with caution in patients with coagulopathies.

Reproductive/Nursing Safety

Safe use in pregnancy has not been established; these products are not recommended for use in pregnant human patients. Use cautiously in veterinary patients.

Overdosage/Acute Toxicity

With products containing vitamin A, acute toxicosis may result after accidental overdoses. Contact a poison control center for additional information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fatty acids/fish oils and may be of significance in veterinary patients:

- **ANTICOAGULANTS:** Because of potential affects on bleeding times, use with caution in patients receiving anticoagulant medications such as aspirin, warfarin, or heparin

Doses

■ DOGS & CATS:

Because of the unique nature of each commercially available product, see the actual label directions of that product for specific dosage recommendations.

- a) A few published clinical articles suggest that (for pruritus in dogs) a beneficial dose for eicosapentanoic acid (EPA) is around 22 mg/kg/day. (White 2003a)

Monitoring

- Efficacy
- Adverse effects

Chemistry/Synonyms/Storage/Stability/Compatibility

The commercially available veterinary products generally contain a combination of fish oil (eicosapentanoic and docosahexanoic acids) and vegetable oil (gamma linolenic acid) that serve as essential fatty acids. They may also contain vitamin E (d-alpha tocopherol) and vitamin A.

The oral capsules should be stored in tight containers and protected from heat (cool, dry place).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

There are many combination products available without prescription having various trade names, including (partial listing): *Dermapet Eicosderm*®, *Dermapet OFA plus EZ-C Caps*®, *F.A. Caps*®, *F.A. Caps ES*®, *Omega EFA*® Capsules, *Omega EFA*® Capsules XS, *Performer*® OFA Gel Capsules Extra Strength, etc.

HUMAN-LABELED PRODUCTS:

There are many fish oil or flaxseed oil capsules available without prescription having various trade names.

Febantel—See the product *Drontal*® Plus listed in the Praziquantel and Pyrantel monographs

FELBAMATE

(*fell*-ba-mate) Felbatol®

ANTICONVULSANT

Prescriber Highlights

- 3rd line antiseizure medication for dogs
- Appears relatively safe to use in dogs, but because of limited use, adverse effect profile may be incomplete
- Cost & accessibility may be issues

Uses/Indications

Felbamate is an anticonvulsant agent that may useful for treating seizure disorders (especially complex partial seizures) in dogs. A potential advantage of felbamate therapy is that when used alone or in combination with phenobarbital and/or bromides, it does not appear to cause additive sedation.

Pharmacology/Actions

Felbamate's anticonvulsant activity is thought to be due its ability to reduce excitatory neurotransmission; its exact mechanism is unknown, but it is believed to increase activation of sodium channels thereby decreasing sustained high-frequency firing of action potentials.

Pharmacokinetics

Felbamate is well absorbed after oral administration in dogs. Felbamate is both excreted unchanged and as metabolites in the urine (about 50:50). The half-life in dogs may range from 5–14 hours. Because the drug can induce liver enzyme induction, half-lives may decrease with time and dosages may need adjustment.

Contraindications/Precautions/Warnings

Felbamate is contraindicated in patients hypersensitive to it or other carbamates (meprobamate). In humans, felbamate should not be used in patients with a history of blood dyscrasias or hepatic dysfunction. In dogs, however, these are probably only cautions since dogs who require felbamate are often close to euthanasia due to the refractoriness of their conditions and a lack of evidence that felbamate causes liver toxicity in dogs.

Adverse Effects

Potential adverse reactions in the dog include liver enzyme induction, tremor, limb rigidity, salivation, restlessness and agitation (at high doses). In humans, aplastic anemia and hepatic necrosis have been noted and could be a factor in canine medicine. There apparently have not been any case reports yet of aplastic anemia in dogs, but blood dyscrasias (thrombocytopenia, lymphopenia, and leukopenia) have been reported. Sedation, and vomiting/nausea have been reported in dogs, but usually in those receiving other anticonvulsants as well.

Reproductive/Nursing Safety

Although no overt teratogenicity has been documented, felbamate should only be used during pregnancy when its potential benefits outweigh its potential risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

The drug is excreted into maternal milk, but adverse consequences to nursing puppies appear remote.

Overdosage/Acute Toxicity

Limited information is available. One human subject taking 12 grams over 12 hours only developed mild gastric distress and a slightly increased heart rate.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving felbamate and may be of significance in veterinary patients:

- **PHENOBARBITAL:** When felbamate is added to patients taking phenobarbital it may cause increases in phenobarbital levels. When phenobarbital is added to patients taking felbamate, felbamate levels may decrease. The same effect can occur with **phenytoin**.
- **VALPROATE:** Felbamate can cause increases in valproic acid levels

Doses■ **DOGS:**

For seizures:

- a) As a third choice antiepileptic agent: 15–65 mg/kg PO q8h. Steady state reached after 4th oral dose. Monitor CBC and liver function tests as you would for phenobarbital. Therapeutic serum concentration reported to be 15–100 mcg/mL. (Quesnel 2000)
- b) For patients on phenobarb and bromides (both in therapeutic range) and seizure activity unchanged or having intolerable side effects with this combination: If intolerable side effects, do levels and decrease the dose of the one that is in the high end of the range. Then add felbamate at 5–20 mg/kg PO three times daily. (Neer 2000)
- c) In dogs refractory to phenobarbital and bromides: Felbamate initial dose of 15 mg/kg PO q8h. May increase the dose in 15 mg/kg increments every 2 weeks until seizures are controlled. Dosages as high as 70 mg/kg, q8h may be necessary and be tolerated by some dogs. (Thomas 2000)

Monitoring

- There is some controversy about monitoring felbamate use in dogs, probably since there is such limited experience with its use. Some clinicians state that liver function tests and CBC's should be regularly assessed (q2–3 months). Others state that the drug is very safe in dogs and that monitoring does not appear to be necessary. Clearly, if the dog is receiving other drugs (especially phenobarbital), monitoring is essential.
- Therapeutic drug levels for felbamate in dogs are not truly known, but appear to be in the 25–100 mcg/mL range. The usefulness of monitoring serum levels is questionable at this point.

Client Information

- Clients must understand the importance of giving doses as prescribed. Because of its short half-life, three times daily administration is routinely administered to adequately judge the efficacy of this drug.
- Because felbamate use in dogs has been limited, the adverse effect profile and possible incidence of serious effects (liver, blood) is not truly known.

Chemistry/Synonyms

Felbamate is a unique dicarbamate anticonvulsant agent, that is slightly soluble in water.

Felbamate may also be known by as: AD-03055, W-554, *Felbamyl*®, *Felbatol*®, *Taloxa*®, and *Taloxa*®.

Storage/Stability/Compatibility

Felbamate preparations should be stored at room temperature. The suspension should be shaken well before use.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Felbamate Tablets: 400 mg, & 600 mg; *Felbatol*® (Wallace Labs); (Rx)

Felbamate Suspension: 120 mg/mL in 240 and 960 mL: *Felbatol*® (Wallace Labs); (Rx)

FENBENDAZOLE

(fen-ben-da-zole) Panacur®, Safe-Guard®

ANTIPARASITIC AGENT**Prescriber Highlights**

- Anthelmintic useful for a variety of parasites in dogs, cats, cattle, horses, swine, etc
- Adverse Effects: Antigen release by dying parasites may occur; particularly at high dosages; vomiting may occur infrequently in dogs or cats

Uses/Indications

Fenbendazole is indicated (labeled) for the removal of the following parasites in dogs: ascarids (*Toxocara canis*, *T. leonina*), Hookworms (*Ancylostoma caninum*, *Uncinaria stenocephala*), whipworms (*Trichuris vulpis*), and tapeworms (*Taenia pisiformis*). It is not effective against *Dipylidium caninum*. Fenbendazole has also been used clinically to treat *Capillaria aerophilus*, *Filaroides hirthi*, and *Paragonimus kellicotti* infections in dogs.

Fenbendazole is indicated (labeled) for the removal of the following parasites in cattle: Adult forms of: *Haemonchus contortus*, *Ostertagia ostertagi*, *Trichostrongylus axei*, *Bunostomum phlebotomum*, *Nematodirus helvetianus*, *Cooperia* spp., *Trichostrongylus colubriformis*, *Oesophagostomum radiatum*, and *Dictyocaulus viviparus*. It is also effective against most immature stages of the above listed parasites. Although not approved, it has good activity against *Moniezia* spp., and arrested 4th stage forms of *Ostertagia ostertagi*.

Fenbendazole is indicated (labeled) for the removal of the following parasites in horses: large strongyles (*S. edentatus*, *S. equinus*, *S. vulgaris*), small strongyles (*Cyathostomum* spp., *Cylicocyclus* spp., *Cylicostephanus* spp., *Triodontophorus* spp.), and pinworms (*Oxyuris equi*).

Fenbendazole is indicated (labeled) for the removal of the following parasites in swine: large roundworms (*Ascaris suum*), lungworms (*Metastrongylus* pair), nodular worms (*Oesophagostomum dentatum*, *O. quadrispinolatum*), small stomach worms (*Hyostomylus rubidus*), whipworms (*Trichuris suis*), and kidney worms (*Stephanurus dentatus*; both mature and immature).

Although not approved, fenbendazole has been used in cats, sheep, goats, pet birds, and llamas. See Dosage section for more information.

Pharmacology/Actions

Benzimidazole antiparasitic agents have a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, their mechanism of action is believed due to disrupting intracellular microtubular transport systems by binding selectively and damaging tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles also act at higher concentrations to disrupt metabolic pathways within the helminth, and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase.

Pharmacokinetics

Fenbendazole is only marginally absorbed after oral administration. After oral dosing in calves and horses, peak blood levels of 0.11 micrograms/mL and 0.07 micrograms/mL, respectively, were measured. Absorbed fenbendazole is metabolized (and vice-versa) to the active compound, oxfendazole (sulfoxide) and the sulfone. In sheep, cattle, and pigs, 44–50% of a dose of fenbendazole is excreted unchanged in the feces, and <1% in the urine.

Contraindications/Precautions/Warnings

Fenbendazole is not approved for use in horses intended for food purposes.

Adverse Effects

At usual doses, fenbendazole generally does not cause any adverse effects. Hypersensitivity reactions secondary to antigen release by dying parasites may occur, particularly at high dosages. Vomiting may infrequently occur in dogs or cats receiving fenbendazole. Pancytopenia has been reported in one dog.

Single doses (even at exaggerated doses) are not effective in dogs and cats; must treat for 3 days.

Reproductive/Nursing Safety

Fenbendazole is considered safe to use in pregnant bitches and is generally considered safe to use in pregnancy for all species. In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Overdosage/Toxicity

Fenbendazole is apparently well tolerated at doses up to 100X recommended. The LD₅₀ in laboratory animals exceeds 10 grams/kg when administered PO. It is unlikely an acute overdosage would lead to clinical signs.

Drug Interactions

■ **BROMSALAN FLUKICIDES** (**dibromsalan**, **tribromsalan**; not available in the USA): Oxfendazole or fenbendazole should not be given concurrently with the bromsalan flukicides; abortions in cattle and death in sheep have been reported after using these compounds together

Doses

■ DOGS:

For susceptible ascarids, hookworms, whipworms, and tapeworms (*Taenia* spp. only):

- 50 mg/kg, PO for 3 consecutive days (Package insert; Panacur®—Hoechst), (Cornelius and Roberson 1986)
- 55 mg/kg, PO for 3 days (5 days for *Taenia*) (Chiappella 1988), (Reinemeyer 1985)

To prevent transplacental and transmammary transmission of somatic *T. canis* and *A. caninum*:

- 50 mg/kg PO once daily from the 40th day of gestation to the 14th day of lactation. (Kazacos 2002)

For *Capillaria plica*:

- 50 mg/kg once daily for 3 days; repeat a single 50 mg/kg dose 3 weeks later (Todd, Paul, and DiPietro 1985)
- 50 mg/kg, PO daily for 3–10 days (Brown and Prestwood 1986)

For *Capillaria aerophila*:

- 25–50 mg/kg q12h for 10–14 days (Hawkins, Ettinger, and Suter 1989); (Hawkins 2000)
- 50 mg/kg PO once daily for 10–14 days (Reinemeyer 1995)

For *Filaroides hirthei*:

- 50 mg/kg, PO once daily for 14 days. Symptoms may worsen during therapy, presumably due to a reaction when the worm dies. (Hawkins, Ettinger, and Suter 1989)
- 50 mg/kg PO once daily for 10–14 days (Reinemeyer 1995)

For *Paragonimus kellicotti*:

- 25–50 mg/kg PO twice daily for 10–14 days (Todd, Paul, and DiPietro 1985); (Hawkins 2000)
- 50 mg/kg PO once daily for 10–14 days (Reinemeyer 1995)
- 50 mg/kg, PO once daily for 3 consecutive days; repeat in 2–3 weeks and again in 2 months (DeNovo 1988)

For *Crenosoma vulpis*:

- 50 mg/kg PO once daily for 3 days (Reinemeyer 1995); (Hawkins 2000)

For Giardia:

- 50 mg/kg PO once daily for 3 days (Barr and Bowman 1994); (Greene and Watson 1998)
- 25 mg/kg PO q12h for 3–7 days (Lappin 2000)

For *Eucoleus boehmi*:

- 50 mg/kg PO once daily for 10–14 days; improvement may only be temporary (Reinemeyer 1995)

■ CATS, DOMESTIC:

For susceptible ascarids, hookworms, strongyloides, and tapeworms (*Taenia* spp. only):

- 50 mg/kg, PO for 5 days (Dimski 1989)

For lungworms (*Aelurostrongylus abstrusus*):

- 25–50 mg/kg q12h for 10–14 days (Hawkins, Ettinger, and Suter 1989); (Hawkins 2000)
- 50 mg/kg, PO for 10 days (Pechman 1989)
- 20 mg/kg PO once daily for 5 days; repeat in 5 days (Reinemeyer 1995)

For lungworms (*Capillaria aerophila*):

- 50 mg/kg, PO for 10 days (Pechman 1989)
- 50 mg/kg PO once daily for 10–14 days (Reinemeyer 1995)

For *Capillaria feliscati*:

- 25 mg/kg, twice daily PO for 3–10 days (Brown and Prestwood 1986)
- 25 mg/kg, PO q12h for 10 days (Brown and Barsanti 1989)

For *Paragonimus kellicotti*:

- 25–50 mg/kg PO twice daily for 10–14 days (Hawkins 2000)
- 50 mg/kg PO once daily for 10–14 days (Reinemeyer 1995)

For *Eurytrema procyonis* (pancreatic fluke):

- 30 mg/kg, PO daily for 6 days (Steiner and Williams 2000)

For Giardia:

- In young kittens: 50 mg/kg PO (using the suspension) once a day for 3–5 days (Tams 1999)
- 50 mg/kg PO q24h for 3–5 days (Vasilopoulos 2006)

■ CATS, LARGE (EXOTIC):

For labeled parasites:

- a) 10 mg/kg PO once daily for 3 consecutive days. (Label information; *Panacur*® 22.25 Granules—Intervet)

■ BEARS (*URSIDAE*):

For labeled parasites:

- a) 10 mg/kg PO once daily for 3 consecutive days. (Label information; *Panacur*® 22.25 Granules—Intervet)

■ SMALL MAMMALS/RODENTS:

- a) For pinworms in mice, rats, hamsters, gerbils and rabbits: 50 mg/kg PO once (Burke 1999)
- b) For *Giardia* in Chinchillas: 25 mg/kg PO once a day for 3 days (Hayes 2000)
- c) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 20–50 mg/kg PO once daily for 5 days (Higher dose is for *Giardia*) (Adamcak and Otten 2000)

■ CATTLE:

For removal/control of *Haemonchus contortus*, *Ostertagia ostertagi*, *Trichostrongylus axei*, *Bunostomum phlebotomum*, *Nematodirus helvetianus*, *Cooperia* spp., *Trichostrongylus colubriformis*, *Oesophagostomum radiatum*, and *Dictyocaulus viviparus*:

- a) 5 mg/kg, PO (Paul 1986)
- b) 7.5 mg/kg, PO (Roberson 1988b)
- c) 4 mg/kg PO; under conditions of continuous exposure to parasites, animals may need to be retreated after 4–6 weeks, (Label information *Panacur*® Paste—Intervet)

For *Moniezia* spp., and arrested 4th stage forms of *Ostertagia ostertagi*:

- a) 10 mg/kg, PO (Paul 1986), (Roberson 1988b)

For giardiasis in calves:

- a) 15 mg/kg PO for 3 successive days and then moved to a pen that was thoroughly cleaned and disinfected with 10% ammonia. (Claerebout 2006)

■ HORSES:

For susceptible parasites:

- a) For control of large and small strongyles, and pinworms in adult horses: 5 mg/kg PO;
For foals and weanlings (less than 18 months of age) where ascarids are a common problem: 10 mg/kg PO;
For control of encysted early 3rd stage, late 3rd stage and 4th stage cyathostome larvae and 4th stage *Strongylus vulgaris* larvae 10 mg/kg PO for 5 consecutive days. (Label information *Panacur*® Paste—Intervet)

For treatment of migrating large strongyles:

- a) 50 mg/kg PO for 3 consecutive days, or 10 mg/kg for 5 consecutive days (Herd 1987)

For mucosal stage of small strongyles:

- a) 7.5–10 mg/kg PO once daily for 5 days; a single dose of 30 mg/kg is effective against older encysted stages (Lyons and Drudge 2000)

■ SWINE:

For susceptible parasites:

- a) 5 mg/kg PO; 3 mg/kg in feed for 3 days; 10 mg/kg for ascarids (Roberson 1988b)
- b) For whipworms in potbellied pigs: 9 mg/kg PO for days (Braun 1995)

■ SHEEP & GOATS:

For susceptible parasites:

- a) 5 mg/kg in feed for 3 days (Roberson 1988b)

■ LLAMAS:

For susceptible parasites:

- a) 10–15 mg/kg PO (as paste or suspension) (Fowler 1989)
- b) 5–10 mg/kg PO for 1–3 days. Fenbendazole and ivermectin are the most effective and safest anthelmintics for use in llamas. (Cheney and Allen 1989)

■ BIRDS:

- a) For Ascarids: 10–50 mg/kg PO once; repeat in 10 days. Do not use during molt (may cause stunted feathers) or while nesting.

For flukes or microfilaria: 10–50 mg/kg PO once daily for 3 days

For *Capillaria*: 10–50 mg/kg PO once daily for 5 days. Is not effective against gizzard worms in finches. (Clubb 1986)

- b) For nematodes, some trematodes: 10–50 mg/kg PO once daily for 3–5 days; 20–100 mg/kg oral single dose range; 125 mg/L of drinking water for 5 days (50 mg/L for 5 days in finches); or 100 mg/kg of feed for 5 days. Not recommended to be used in breeding season during molting. (Marshall 1993)
- c) Ratites: 15 mg/kg PO once daily for 3 days. Has efficacy against ostrich tapeworm. (*Houttuynia struthionus*) (Jenson 1998)

■ REPTILES:

For susceptible infections:

- a) For most species: 50–100 mg/kg PO once; repeat in 2–3 weeks; very effective against Strongyloides. (Gauvin 1993)

Chemistry/Synonyms

A benzimidazole anthelmintic, fenbendazole occurs as a white, crystalline powder. It is only slightly soluble in water.

Fenbendazole may also be known as: Hoe-881V, *Panacur*®, and *Safe-Guard*®.

Storage/Stability

Fenbendazole products should be stored at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Fenbendazole Granules: 222 mg/gram (22.2%) in 0.18 oz and 1 g, 2 g, 4 g packets and 1 lb jars; *Panacur*® Granules 22.2% (Intervet); (Rx); *Safeguard*® Canine Dewormer (Intervet), (OTC). Approved for use in dogs, large exotic cats (lions, etc.), and bears (black bears, polar bears, etc.)

Fenbendazole Granules: 222 mg/gram (22.2%); *Panacur*® Granules 22.2% (Intervet). (OTC). Approved for use in horses not intended for food.

Fenbendazole Suspension: 100 mg/mL (10%); available in both equine and bovine labeled products; *Panacur*® Suspension (Intervet); (Rx). Approved for use in horses (not intended for food) and cattle Slaughter withdrawal = 8 days (cattle). *Safe-Guard*® Suspension (Intervet); (OTC). Approved for use in beef and dairy cattle. Slaughter withdrawal at labeled doses = 8 days

Fenbendazole Paste: 100 mg/gram (10%); available in both equine and bovine labeled products and sizes. *Panacur*® Paste (Intervet); (OTC). Approved for use in horses (not intended for food) and cattle. Slaughter withdrawal at labeled doses = 8 days (cattle). *Safe Guard*® Paste (Intervet); (OTC). Approved for use in horses not intended for food and cattle. Slaughter withdrawal at labeled doses = 8 days; no milk withdrawal time at labeled doses.

Fenbendazole Type B Medicated Feed

Safe-Guard® EZ Scoop Swine Dewormer (Intervet) (OTC). 1.8% Fenbendazole. No slaughter withdrawal time required at labeled doses.

Safe-Guard® 0.96% Scoop Dewormer (Intervet); (OTC). Approved for use in cattle. No milk withdrawal time; slaughter withdrawal time at labeled doses = 13 days.

Fenbendazole Type C Medicated Feed

Safe-Guard® Free-choice Cattle Dewormer (Intervet); (OTC); 0.50% Fenbendazole (2.27 g/lb). Approved for use in beef and dairy cattle. No milk withdrawal time.

Safe-Guard® 35% Salt Free-choice Cattle Dewormer (Intervet); (OTC); 1.9 g/lb Fenbendazole. Approved for use in dairy and beef cattle. Slaughter withdrawal time at labeled doses = 13 days; no milk withdrawal time.

Fenbendazole Pellets

Safe-Guard® 0.5% Cattle Top Dress (Intervet); (OTC). At labeled dose, slaughter withdrawal time = 13 days; no milk withdrawal period at labeled doses.

Safe-Guard® 1.96% Scoop Dewormer Mini Pellets (Intervet); (OTC). Approved for use in beef and dairy cattle. No milk withdrawal time at labeled doses; slaughter withdrawal time at labeled doses = 13 days.

Fenbendazole Premix 20% Type A (200 mg/gram)

Safe-Guard® Premix (Intervet); (OTC). Approved for use in swine, growing turkeys, dairy and beef cattle, zoo and wildlife animals. Slaughter withdrawal for cattle = 13 days; no milk withdrawal time. Slaughter withdrawal for swine at labeled doses = none. Wildlife animal slaughter (hunting) withdrawal = 14 days at labeled doses.

HUMAN-LABELED PRODUCTS: None

FENTANYL, TRANSDERMAL FENTANYL CITRATE

(*fen*-ta-nil) Sublimaze®, Duragesic®

OPIATE

Prescriber Highlights

- ▶ **Class-II opiate analgesic used parenterally & transdermally in small animals**
- ▶ **Contraindications:** Use extreme caution when additional respiratory, or CNS depression would be deleterious
- ▶ **Use caution in geriatric, very ill or debilitated patients & those with a preexisting respiratory problem**
- ▶ **Adverse Effects:** Dose related respiratory, CNS & circulatory depression (bradycardia); also, rashes at the patch site, urine retention, constipation, dysphoria, or agitation
- ▶ **Do NOT cut patches; dispose of properly**
- ▶ **Lab values (amylase, lipase) may be altered**

Uses/Indications

In veterinary medicine, fentanyl injection and transdermal patches are used primarily in dogs and cats and have been shown to be useful for the adjunctive control of postoperative pain and in the control of severe pain associated with chronic pain, dull pain, and non-specific, widespread pain (e.g., associated with cancer, pancreatitis, aortic thromboemboli, peritonitis, etc.). Perioperative in-

jectable fentanyl can also reduce the requirements for inhalational anesthetics during surgery, which can be particularly advantageous in patients with compromised cardiac function. Transdermal fentanyl has been clinically effective overall and has not demonstrated substantial adverse effects.

In humans, significant respiratory depression with use of the patches after surgery has precluded post-operative use, but this has not been a significant problem in veterinary medicine.

Pharmacology/Actions

Fentanyl is a *mu* opiate agonist. *Mu* receptors are found primarily in the pain regulating areas of the brain. They are thought to contribute to the analgesia, euphoria, respiratory depression, physical dependence, miosis, and hypothermic actions of opiates. Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and mid-brain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle.

The pharmacology of the opiate agonists is discussed in more detail in the monograph, *Narcotic (opiate) Agonist Analgesics*.

Pharmacokinetics

When used via a single dose IV injection, fentanyl has a relatively short duration of effect (15–30 minutes.)

When administered to dogs as 10 mcg/kg IV bolus, fentanyl rapidly distributes and exhibits a large volume of distribution (5 L/kg). The terminal elimination half life is about 45 minutes; total clearance is 78 mL/min/kg. After a 10 mcg/kg bolus, dogs administered a constant rate intravenous infusion of 10 mg/kg/hr were able to maintain blood levels around 1 ng/mL (the assumed—but not verified therapeutic analgesic level). (Sano, Nishimura et al. 2006)

Half-life after IV administration in cats is approximately 2.5 hours.

There have been limited pharmacokinetic studies performed with transdermal fentanyl patches in dogs, cats, and horses. While therapeutic levels of fentanyl are attained, there is a significant interpatient variability with both the time to achieve therapeutic levels and the levels themselves. Cats tend to achieve therapeutic levels faster than do dogs; in dogs, the patch should be applied 24 hours in advance of need if possible; minimum of 12 hours pre-need. Most cats attain therapeutic benefit in about 6 hours after application. While applied, duration of action persists for at least 72 hours (usually for at least 104 hours). Duration of action is generally longer in cats than in dogs. For continued use, patches may need to be changed every 48 hours in dogs or horses.

In horses, fentanyl patches are rapidly absorbed with therapeutic levels (1 ng/mL?) achieved in about 6 hours after application and persists for 48+ hours.

Contraindications/Precautions/Warnings

Fentanyl is contraindicated in patients with known hypersensitivity to it or any component of the product (including the adhesive for the patch).

Because of its potency, fentanyl injection should be used only by professionals familiar with its use in circumstances where patients can be adequately monitored and supported.

Use cautiously with other CNS depressants. Dosages of other opiates may need to be reduced when given with fentanyl transdermal, particularly several hours after application of the patch. Transdermal fentanyl should be used cautiously in geriatric, very ill or debilitated patients and those with a preexisting respiratory problem. Febrile patients may have increased absorption of fentanyl and will require increased monitoring.

Patches must not be cut. Do not allow applied fentanyl patch to be exposed to exogenous heat sources (heating pads, etc.). Increased drug release and absorption have occurred with fatal results.

Adverse Effects

Dose related respiratory, CNS and circulatory depression (bradycardia) are the primary adverse effects with fentanyl injection. Dogs and cats appear less prone, but not immune to opiate-induced respiratory depression, than are humans.

Respiratory depression and bradycardia associated with fentanyl patches are the most concerning adverse effects, but incidence of these effects have not been widespread thus far when used alone (without other opiates or other respiratory and cardiodepressant medications). Rashes at the patch site have been reported and should they occur, the patch should be removed; if an additional patch is warranted, a different site should be chosen. Urine retention and constipation may occur. Consider removing patch in patients developing a fever after application, as fentanyl absorption may increase. Some patients exhibit dysphoria or agitation after application; acepromazine or other mild tranquilizer may alleviate dysphoria.

Reproductive/Nursing Safety

Safe use in pregnancy has not been established. In humans, the FDA categorizes fentanyl as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Most narcotic agonist analgesics are excreted into milk, but effects on nursing offspring may not be significant.

Overdosage/Acute Toxicity

Overdosage may produce profound respiratory and/or CNS depression in most species. Newborns may be more susceptible to these effects than adult animals. Other toxic effects may include cardiovascular collapse, tremors, neck rigidity, and seizures. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated; animals should be closely observed as naloxone's effects sometimes diminish before sub-toxic levels of fentanyl are attained. Mechanical respiratory support should also be considered in cases of severe respiratory depression.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fentanyl and may be of significance in veterinary patients:

- **AZOLE ANTIFUNGALS** (**ketoconazole**, **itraconazole**, **fluconazole**): May inhibit fentanyl metabolism
- **CNS DEPRESSANTS, OTHER**: Additive CNS effects possible
- **DIURETICS**: Opiates may decrease efficacy in CHF patients
- **MACROLIDE ANTIBIOTICS** (**erythromycin**, **clarithromycin**): May inhibit fentanyl metabolism
- **MONOAMINE OXIDASE INHIBITORS** (*e.g.*, **amitraz**, and possibly **selegiline**): Severe and unpredictable opiate potentiation may be seen; not recommended (in humans) if MAO inhibitor has been used within 14 days)
- **MUSCLE RELAXANTS, SKELETAL**: Fentanyl may enhance neuromuscular blockade

- **NITROUS OXIDE**: High fentanyl doses may cause cardiovascular depression
- **PHENOBARBITAL, PHENYTOIN**: May increase the metabolism of fentanyl
- **RIFAMPIN**: May increase the metabolism of fentanyl
- **TRICYCLIC ANTIDEPRESSANTS** (**clomipramine**, **amitriptyline**, etc.): Fentanyl may exacerbate the effects of tricyclic antidepressants
- **WARFARIN**: Opiates may potentiate anticoagulant activity

Laboratory Considerations

- As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

Doses

■ DOGS:

Fentanyl Injectable:

- a) For perioperative pain: The combination of a 10 mcg/kg loading dose IV followed by a CRI of 10 mcg/kg/hour investigated in this study might be a guideline for a CRI dose of fentanyl during general anesthesia to provide analgesia in dogs. (Sano, Nishimura et al. 2006)
- b) Loading dose: 2–5 mcg/kg IV, followed by a CRI at 2–5 mcg/kg/hr for pain management; CRI at 10–45 mcg/kg/hr for surgical analgesia. (Wagner 2002)
- c) For perioperative pain: 5–10 mcg/kg/hr IV or CRI (Tranquilli 2003)
- d) For induction: 0.001–0.005 mg/kg IV. For MAC reduction during general anesthesia: 10–45 mcg/kg/hr CRI. (Mama 2002b)

Fentanyl Transdermal:

Note: There is significant interpatient variability on the response of the transdermal product. When used as the primary analgesic for post-operative pain, application prior to surgery is advised as many hours may be required for “therapeutic” levels to be achieved. Generally in dogs = 12–24 hours may be necessary; cats = 6–24 hours; and horses = 6+ hours.

The following dosage regimen has been used at the University of Minnesota Veterinary Medical Center and is adapted from information provided by Dr. Lynelle Graham:

Choose your patient carefully, realizing that the fentanyl patch alone may not provide sufficient analgesia. Fentanyl patches are effective for relief of chronic pain, dull pain and non-specific, widespread pain (peritonitis, pancreatitis, cancer, aortic thromboemboli, declaws, etc.) In the face of acute surgical pain or severe traumatic pain (fractures, thoracotomies, HBC/traumatic injuries/head trauma), analgesia provided by a fentanyl patch tends to be inadequate. Therefore, the patch should be used as an adjunctive measure for pain relief in these patients. If the patient is febrile, do not use fentanyl patch.

Choose your Patch Size:

PATIENT	DOSE (PATCH SIZE)	FENTANYL CONTENT
Small Dogs (<5kg)** and Cats**	25 mcg/hr or 12.5 mcg/hr	2.5 mg; 1.25 mg
Dogs: 5–10 kg	25 mcg/hr	2.5 mg
Dogs: 10–20 kg	50 mcg/hr	5 mg
Dogs: 20–30 kg	75 mcg/hr	7.5 mg
Dogs: >30 kg	100 mcg/hr	10 mg
Horses: 350–500 kg	2 x 100 mcg/hr	20 mg
Pigs: 17–25 kg	50–100 mcg/hr	5–10 mg
Sheep	1–3 x 50 mcg/hr	5–15 mg
Goats	50 mcg/hr	5 mg
Rabbits	25 mcg/hr	2.5 mg

(**These patients can be dosed with ½ of a 25 mcg/hr patch, *i.e.*, only half of the membrane is exposed to the patient's skin (cover the other half with tape); DO NOT CUT the patch in half, as this will alter the drug releasing membrane and allow evaporation of the fentanyl-containing alcohol-cellulose gel. Current research suggests dosing with a whole 25 mcg/hr patch in otherwise healthy patients of this size (*i.e.*, fractures, declaws). However, in order to avoid sedation, "half-patch" dosing may be desired for pediatric, geriatric, and systemically ill cats and very small dogs, but this is controversial.

Choose your location:

DOG: Thorax, inguinal area, metatarsal/carpal areas, base of tail (dorsal or lateral cervical area has been used, but leashes must not be placed around the neck if fentanyl patches are in place)

CAT: Lateral thorax, inguinal area, metatarsal/carpal areas; base of tail (the cervical area is NOT recommended, as the patch tends not to remain on)

HORSE: Neck, antebrachium

PIG, RABBIT: Lateral thorax

SHEEP, GOAT: Abdomen, cervical area

Note: Direct patch contact with heating pads can significantly increase fentanyl absorption and risk toxicity. The patch should be kept dry; be aware of potential surgical clip sites.

- 1) Clip close, but don't shave, the site. DO NOT use depilatory agents in preparation of the site. Clip at least a 1 cm margin around the patch.
- 2) Wipe the site with a damp cloth and allow the skin to dry. This step is absolutely necessary, or patch will not stick to the skin. DO NOT wipe the area with alcohol or surgical scrub solution. Alcohol and surgical scrubs may "de-fat" the skin and alter drug absorption.
- 3) Place the patch on the skin and hold it in place with the palm of your hand for 2–3 minutes. The heat of your hand will help the adhesive bond to the skin. Failure to perform this step will allow the patch to fall off. If patch is not fully adhered to the skin, fentanyl will not be absorbed properly.
- 4) Cover the patch with a light bandage or clear adhesive bandage (*i.e.*, *Bioclusive*®, Johnson and Johnson, Arlington, TX). If you choose to use *Bioclusive*®, apply the fentanyl patch as described above. Spray around the perimeter and over the

patch with medical adhesive spray (*Medical Adhesive*®, Hollister, Libertyville, IL). Place the *Bioclusive*® over the site and press it down firmly. Be sure to clip an area large enough so that the *Bioclusive*® can adhere to the patch and the skin. If the *Bioclusive*® can only adhere to the patch and fur, without good adherence to skin, the patch will tend to peel up and dislodge.

- 5) Label the site with the size of patch (25, 50, 75 or 100 mcg/hr) and the date and time the patch was placed. Patches have shown to release effective fentanyl levels for up to five days in cats, three days in dogs and two days in horses. Potentially, the patches could be left longer, especially in dogs; this decision can be made by the attending clinician.
- 6) Potential side effects include bradycardia, respiratory depression, urinary retention, and constipation. All patients with fentanyl patches should be monitored accordingly. If a patient with a patch develops a fever, consider patch removal. If the patch is left in place, the patient must be closely monitored since the rate of fentanyl absorption may increase.
- 7) Person applying or removing the patch must gently, but thoroughly rinse their hands with water to remove any drug residue. Soap, cleansers or solvents should not be used. Surgical gloves may be worn to place or remove patches, as skin contact does occur when handling the adhesive edges.
- 8) Dispose of used patches in a safe and effective manner.

■ CATS:

Fentanyl Injectable:

- a) For perioperative pain: 2–3 mcg/kg IV plus 2–3 mcg/kg/hour IV infusion (Pascoe 2000)
- b) Loading dose: 1–3 mcg/kg IV, followed by a CRI at 1–4 mcg/kg/hr for pain management; CRI at 10–30 mcg/kg/hr for surgical analgesia. (Wagner 2002)
- c) For perioperative pain: 2.5–5 mcg/kg/hr IV or CRI (Tranquilli 2003)
- d) For induction: 0.001–0.002 mg/kg IV. For MAC reduction during general anesthesia: 10–20 mcg/kg/hr CRI. (Mama 2002b)

Fentanyl Transdermal: See above in dog dose section

■ FERRETS:

Fentanyl Injectable:

- a) Pre-op dose: 5–10 mcg/kg IV; Intra-operatively: CRI at 10–20 mcg/kg/hr with a ketamine CRI (0.3–0.4 mg/kg/hr); Post-operatively: 2–5 mcg/kg/hr with a ketamine CRI. (Lichtenberger 2006c)

■ RABBITS/RODENTS/SMALL MAMMALS:

Fentanyl Injectable:

- a) For perioperative pain: 5–20 mcg/kg IV bolus (30–60 minute duration; causes sedation and respiratory depression) (Ivey and Morrissey 2000)

Fentanyl Transdermal:

- a) Rabbits for postoperative analgesia: ½ small patch (25 mcg/hr) per medium sized rabbit (3 kg) every 3 days. Do not cut patch (Ivey and Morrissey 2000)
- b) Rabbits: See above in dog dose section

■ HORSES: (Note: ARCI UCGFS Class 1 Drug)

Fentanyl Transdermal: See above in dog dose section

■ SHEEP, GOATS & SWINE:

Fentanyl Transdermal: See above in dog dose section

Monitoring

- Analgesic efficacy
- Heart rate and respiratory rate

Client Information

- Fentanyl injection should be used only by professionals familiar with its use in a setting where adequate monitoring can occur.
- Fentanyl Patches: Explain carefully to clients how to apply (if applicable), remove and dispose of patches. Consider making application, removal, and disposal an outpatient procedure, thereby bypassing concerns with clients.
- Should accidental human skin contact occur with the patch, wash with water only (no soap, etc.). Use cautiously in households where young children or animals could remove and ingest or be exposed to patches.

Chemistry/Synonyms

Fentanyl citrate, a very potent opiate agonist, occurs as a white, crystalline powder. It is sparingly soluble in water and soluble in alcohol. It is odorless and tasteless (not recommended for taste test because of extreme potency) with a pK_a of 8.3 and a melting point between 147°–152°C.

Fentanyl and fentanyl citrate may also be known as: fentanylum, fentanyl citras, McN-JR-4263-49, phentanyl citrate, R-4263, *Actiq*®, *Fenodid*®, *Fenta-Hameln*®, *Fentabbott*®, *Fentanest*®, *Fentax*®, *Fentora*®, *Haldid*®, *Ionsys*®, *Leptanal*®, *Nafluvent*®, *Sinteny*®, *Sublimaze*®, *Tanyl*®, and *Trofentyl*®.

Storage/Stability/Compatibility

Fentanyl transdermal patches should be stored at temperatures less than 25°C and applied immediately after removing from the individually sealed package. Do not cut patches.

The transmucosal (buccal) tablets should be stored at room temperature; do not refrigerate or freeze.

Fentanyl injection should be stored protected from light. It is hydrolyzed in an acidic solution. The injection is **compatible** with normal saline and D5W.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Fentanyl Buccal Tablets: 100 mcg, 200 mcg, 400 mcg, 600 mcg, & 800 mcg with mannitol in color-coded blister packs; *Fentora*® (Cephalon); (Rx, C-II)

Fentanyl Injectable: 0.05 mg/mL (50 mcg/mL) in 2, 5, 10, and 20 mL amps; 30 mL and 50 mL vials; preservative free in 2, 5, 10 mL, & 20 mL amps; *Sublimaze*® (Akorn); generic; (Rx, C-II)

Fentanyl Transdermal System:

1.25 (5 cm²; **12.5 mcg/hr**);

2.5 to 2.75 (6.25–10 cm²; **25 mcg/hr**);

2.5 to 5.5 (12.5–20 cm²; **50 mcg/hr**);

7.5 to 8.25 (18.75–30 cm²; **75 mcg/hr**);

10 to 11 (25–40 cm²; **100 mcg/hr**);

Duragesic®-12, -25, -50, -75 and -100 (Janssen); generic; (Rx, C-II)

Fentanyl Iontophoretic Transdermal System: 40 mcg/dose fentanyl hydrochloride (equivalent to 44.4 mcg of fentanyl) delivered over a 10-minute period upon each activation of the dose button; Each system contains fentanyl hydrochloride 10.8 mg; *Ionsys*® (Ortho-McNeil); (Rx; C-II)

Fentanyl Transmucosal System: Lozenges on a stick: 200 mcg, 400 mcg, 600 mcg, 800 mcg, 1200 mcg and 1600 mcg (as base); *Actiq*® (Cephalon); generic; (Rx, C-II)

All fentanyl products are Class-II controlled substances.

FERROUS SULFATE

(*fer-us sul-fayte*) Fer-In-Sol®, Feosol®

NUTRITIONAL/HEMATINIC**Prescriber Highlights**

- Oral iron supplement for the treatment of iron-deficiency anemias
- Contraindications: Patients with hemosiderosis, hemochromatosis, hemolytic anemias, or known hypersensitivity; some consider it contraindicated with GI ulcers
- Adverse Effects: With non-toxic doses, mild gastrointestinal upset
- May be very toxic (life threatening) if OD'd

Uses/Indications

While iron is a necessary trace element in all hemoglobin-utilizing animals, the use of therapeutic dosages of ferrous sulfate (or other oral iron) preparations in veterinary medicine is limited primarily to the treatment of iron-deficiency anemias in dogs (usually due to chronic blood loss), and as adjunctive therapy in cats when receiving epoetin (erythropoietin) therapy. Injectable iron products are usually used in the treatment of iron deficiency anemias associated with newborn animals.

Pharmacology/Actions

Iron is necessary for myoglobin and hemoglobin in the transport and utilization of oxygen. While neither stimulating erythropoiesis nor correcting hemoglobin abnormalities not caused by iron deficiency, iron administration does correct both physical signs and decreased hemoglobin levels secondary to iron deficiency.

Ionized iron is a component in the enzymes cytochrome oxidase, succinic dehydrogenase, and xanthine oxidase.

Pharmacokinetics

Oral absorption of iron salts is complex and determined by a variety of factors including diet, iron stores present, degree of erythropoiesis, and dose. Iron is thought to be absorbed throughout the GI tract, but is most absorbed in the duodenum and proximal jejunum. Food in the GI tract may reduce the amount absorbed.

After absorption, the ferrous iron is immediately bound to transferrin, transported to the bone marrow and eventually incorporated into hemoglobin. Iron metabolism occurs in a nearly closed system. Because iron liberated by the destruction of hemoglobin is reused by the body and only small amounts are lost by the body via hair and nail growth, normal skin desquamation and GI tract sloughing, normal dietary intake usually is sufficient to maintain iron homeostasis.

Contraindications/Precautions/Warnings

Ferrous sulfate (or other oral iron products) are considered contraindicated in patients with hemosiderosis, hemochromatosis, hemolytic anemias, or known hypersensitivity to any component of the product. Because of the GI irritating properties of the drugs, oral iron products are considered contraindicated by some clinicians in patients with GI ulcerative diseases.

Adverse Effects

Adverse effects associated with non-toxic doses are usually limited to mild gastrointestinal upset. Division of the daily dosage may reduce this effect, but dosage reduction may also be necessary in some animals.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category A for use during pregnancy (*Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Overdosage/Acute Toxicity

Ingestion of iron containing products may result in serious toxicity. While lethal doses are not readily available in domestic species, as little as 400 mg (of elemental iron) is potentially fatal in a child. Initial clinical signs of acute iron poisoning usually present with an acute onset of gastrointestinal irritation and distress (vomiting—possibly hemorrhagic, abdominal pain, diarrhea). The onset of these effects may be seen within 30 minutes of ingestion, but can be delayed for several hours. Peripheral vascular collapse may rapidly follow with clinical signs of depression, weak and/or rapid pulse, hypotension, cyanosis, ataxia, and coma possible. Some patients do not exhibit this phase of toxicity and may be asymptomatic for 12–48 hours after ingestion, when another critical phase may occur. This phase may be exhibited by pulmonary edema, vasomotor collapse, cyanosis, pulmonary edema, fulminant hepatic failure, coma and death. Animals that survive this phase may exhibit long-term sequelae, including gastric scarring and contraction and have persistent digestive disturbances.

Because an acute onset of gastroenteritis may be associated with a multitude of causes, diagnosis of iron intoxication may be difficult unless the animal has been observed ingesting the product or physical evidence suggests ingestion. Ferrous sulfate (and gluconate) tablets are radiopaque and often can be observed on abdominal radiographs. Serum iron levels and total iron binding capacity (TIBC) may also be helpful in determining the diagnosis, but must be done on an emergency basis to have any clinical benefit.

Treatment of iron intoxication must be handled as an emergency. In humans who have ingested 10 mg/kg or more of elemental iron within 4 hours of presentation, the stomach is emptied, preferably using gastric lavage with a large bore tube to remove tablet fragments. It is generally recommended to avoid using emetics in patients who already have had episodes of hemorrhagic vomiting. These patients are lavaged using tepid water or 1–5% sodium bicarbonate solution.

In dogs, one author (Mount 1989), has recommended using oral milk of magnesia to help bind the drug, administering apomorphine if appropriate to help dislodge tablets, and to instill a gastric lavage slurry of 50% sodium bicarbonate with a portion left in the stomach. Deferoxamine is useful in chelating iron that has been absorbed. See that monograph for further information.

In addition to chelation therapy, other supportive measures may be necessary including treatment of acidosis, prophylactic antibiotics, oxygen, treatment for shock, coagulation abnormalities, seizures, and/or hyperthermia. After the acute phases have resolved, dietary evaluation and management may be required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ferrous sulfate and may be of significance in veterinary patients:

- **ANTACIDS:** May bind to iron and decrease oral absorption; administer at least two hours apart
- **CALCIUM (ORAL):** May bind to iron and decrease oral absorption; administer at least two hours apart
- **CHLORAMPHENICOL:** Because chloramphenicol may delay the response to iron administration, avoid using chloramphenicol in patients with iron deficiency anemia
- **FLUOROQUINOLONES (enrofloxacin, etc.):** Iron may reduce the absorption of oral fluoroquinolones; administer at least two hours apart
- **H₂-RECEPTOR ANTAGONISTS (e.g., ranitidine, famotidine, etc.):** Increased gastric pH may decrease iron absorption
- **PENICILLAMINE:** Iron can decrease the efficacy of penicillamine, probably by decreasing its absorption; if both drugs are required, space doses of the two drugs as far apart as possible
- **PROTON-PUMP INHIBITORS (e.g., omeprazole):** Increased gastric pH may decrease iron absorption
- **TETRACYCLINES:** Oral iron preparations can bind to orally administered tetracyclines, thereby decreasing the absorption of both compounds
- **THYROXINE:** Iron may reduce the absorption of oral thyroxine; administer at least two hours apart
- **VITAMIN C:** May enhance the absorption of iron

Laboratory Considerations

- Large doses of oral iron can color the feces black and cause false-positives with the guaiac test for occult blood in the feces.
- Iron does not usually affect the benzidine test for occult blood.

Doses

CAUTION: Unless otherwise noted, doses are for ferrous sulfate (regular—not dried). Dosing of oral iron products can be confusing; some authors state doses in terms of the iron salt and some state doses in terms of elemental iron. For the doses below, assume that the doses are for ferrous sulfate and not elemental iron, unless specified.

■ DOGS:

For iron deficiency anemia:

- a) 60–300 mg PO per day for 2 weeks or more (Adams 1988a)
- b) First correct underlying cause of blood loss, then give ferrous sulfate at 100–300 mg per day (total dose) PO. Absorption is enhanced if administered 1 hour before or several hours after feeding. Reduce dosage if GI side effects occur. (Harvey, French, and Meyer 1982)

For patients to be treated with epoetin (erythropoietin):

- a) 100–300 mg (total dose) PO per day (Cowgill 2002); (Vaden 2006b)

■ CATS:

For iron deficiency anemia:

- a) 50–100 mg PO once daily (Kirk 1986), (Morgan 1988)
 - b) 30–200 mg PO per day for 2 weeks or more (Adams 1988a)
- For patients to be treated with epoetin (erythropoietin):
- a) 50–100 mg (total dose) PO per day. Many cats do not tolerate oral iron therapy and are better treated with iron dextran at 50 mg IM q3–4 weeks. (Cowgill 2002)
 - b) 5–50 mg per cat PO once daily (DiBartola and Chew 2006a)
 - c) 50–100 mg per cat PO once daily (Vaden 2006b)

■ **CATTLE:**

As a hematinic:

- a) 8–15 g PO per day for 2 weeks or more (Adams 1988a)

■ **HORSES:**

As a hematinic:

- a) 2–8 g PO per day for 2 weeks or more (Adams 1988a)

■ **SWINE:**

As a hematinic:

- a) 0.5–2 g PO per day for 2 weeks or more (Adams 1988a)

■ **SHEEP:**

As a hematinic:

- a) 0.5–2 g PO per day for 2 weeks or more (Adams 1988a)

Monitoring

■ Efficacy; adverse effects:

- a) Hemograms
b) Serum iron and total iron binding capacity, if necessary. Normal serum iron values for dogs and cats are reported as 80–180 micrograms/dl and 70–140 micrograms/dl, respectively. Total iron binding for dogs and cats are reported as 280–340 micrograms/dl and 270–400 micrograms/dl, respectively. (Morgan 1988). Serum transferrin saturation can be estimated by dividing serum iron by total iron binding capacity.

Client Information

- Because of the potential for serious toxicity when overdoses of oral iron-containing products are ingested by either children or animals, these products should be kept well out of reach of children and pets.

Chemistry/Synonyms

An orally available iron supplement, ferrous sulfate occurs as odorless, pale-bluish-green, crystals or granules having a saline, styptic taste. In dry air the drug is efflorescent. If exposed to moisture or moist air, the drug is rapidly oxidized to a brownish-yellow ferric compound that should not be used medicinally. Exposure to light or an alkaline medium will enhance the conversion from the ferrous to ferric state.

Ferrous sulfate is available commercially in two forms, a “regular” and a “dried” form. Regular ferrous sulfate contains 7 molecules of water of hydration and is freely soluble in water and insoluble in alcohol. Ferrous sulfate contains approximately 200 mg of elemental iron per gram. Dried ferrous sulfate consists primarily of the monohydrate with some tetrahydrate. It is slowly soluble in water and insoluble in water. Dried ferrous sulfate contains 300 mg of elemental iron per gram. Ferrous sulfate, dried may also be known as ferrous sulfate, exsiccated.

Ferrous sulfate may also be known as: eisen(II)-sulfat, ferreux (sulfate), ferrosi sulfas heptahydricus, ferrous sulphate, ferrum sulfuricum oxydulatum, iron (II) sulphate heptahydrate, iron sulphate; many trade names are available.

Storage/Stability

Unless otherwise instructed, store ferrous sulfate preparations in tight, light-resistant containers.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

No veterinary-approved products containing only ferrous sulfate could be located, but there are many multivitamin with iron containing products available.

HUMAN-LABELED PRODUCTS:

Ferrous Sulfate Tablets: 325 mg (65 mg iron); *Feosol*® (GlaxoSmithKline); *FeroSul*® (Major); generic; (OTC)

Ferrous Sulfate Elixir/Liquid: 220 mg/5mL (44 mg iron/5ml) in 473 mL, 300 mg/5 mL (60 mg iron/5ml) in 5 mL; *Feosol*® (SmithKline Beecham); generic; (OTC)

Ferrous Sulfate Drops: 75 mg/0.6 mL (15 mg iron/0.6 mL) in 50 mL; *Fer-In-Sol*® (Mead Johnson Nutritionals); *Fer-Gen-Sol*® (Goldline); generic; (OTC)

Ferrous Sulfate, Dried (exsiccated) Tablets: 200 mg (65 mg iron) & 300 mg (60 mg iron); *Feosol*® (GlaxoSmithKline); *Feratab*® (Upsher-Smith); generic (Rugby); (OTC)

Ferrous Sulfate, Dried (exsiccated) Tablets, Slow-Release: 160 mg (50 mg iron); *Slow FE*® (Ciba); *Slow Release Iron*® (Cardinal Health);(OTC)

FILGRASTIM (GRANULOCYTE COLONY STIMULATING FACTOR; GCSF)

(fill-*grass*-stim) Neupogen®

CYTOKINE HEMATOPOIETIC AGENT

Prescriber Highlights

- Cytokine that in the bone marrow primarily increases the proliferation, differentiation, & activation of progenitor cells in the neutrophil-granulocyte line
- Human origin product; antibodies may form that can cause prolonged neutropenia
- Treatment is very expensive

Uses/Indications

Filgrastim may be of benefit in treating neutropenias in dogs or cats when the intrinsic response to endogenously produced cytokines is thought to be inadequate and there is evidence that there are precursors in the bone marrow available. Because of the drug's cost and lack of good evidence for its efficacy in reducing mortality versus using antibiotic therapy alone, its use in small animal medicine is somewhat controversial.

Pharmacology/Actions

Filgrastim is a hematopoietic agent that primarily affects the bone marrow to increase the proliferation, differentiation, and activation of progenitor cells in the neutrophil-granulocyte line. While derived from human DNA, the product is not species specific and also affects canine and feline bone marrow.

Pharmacokinetics

After subcutaneous injection, filgrastim is rapidly absorbed and distributed with highest concentrations found in the bone marrow, liver, kidneys and adrenal glands. It is unknown if it crosses the blood-brain barrier, placenta, or enters maternal milk. The elimination pathways of filgrastim are still under investigation.

Contraindications/Precautions/Warnings

Filgrastim is contraindicated in patients hypersensitive to it. Dogs or cats that have developed antibodies to filgrastim with resultant neutropenia should probably not receive it in the future.

Adverse Effects

Because the human DNA origin product can be immunogenic to dogs and cats, some patients may develop severe neutropenia by mounting an immune response against both endogenously produced and exogenously administered G-CSF. Studies in cats have demonstrated that short pulse doses of 3–5 days at the time of neutropenia may be safe and minimize the development of neutrophil neutralizing antibodies. Preliminary studies using canine origin G-CSF have not demonstrated autoantibody formation in either dogs or cats.

Additionally, there are concerns that exogenously administered filgrastim can elicit undesirable responses in other tissues, including causing myelofibrosis and medullary histiocytosis.

Occasionally irritation at the injection site may occur. Bone pain, splenomegaly, and hypotension have been reported in humans.

Reproductive/Nursing Safety

Adverse effects in females and offspring have been demonstrated after filgrastim was administered to pregnant laboratory animals at high dosages. To interpret this data for use in a clinical setting is difficult, but filgrastim should be used in pregnant females only when the benefits of treating outweigh the potential risks. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether filgrastim is excreted in milk, but it is unlikely to pose significant risk to nursing offspring.

Overdosage/Acute Toxicity

Limited information is available. Because of the expense of the drug and its apparent limited acute toxic potential, clinically significant overdoses are unlikely.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving filgrastim and may be of significance in veterinary patients:

- **ANTINEOPLASTICS:** While filgrastim was developed primarily to prevent the neutropenias associated with some chemotherapeutic agents, some controversy exists about using filgrastim within 24 hours of a dose of antineoplastic agents that target rapidly proliferating cells; generally, in human medicine, use is avoided within 24 hours of such antineoplastics

Doses

Note: To avoid the development of autoantibody formation, most clinicians using this agent recommend using filgrastim in dogs or cats using a “pulse” therapy of no more than 5 days in duration.

■ DOGS:

- a) For adjunctive therapy of neutropenia (secondary to drug induced aplastic pancytopenia): 5 mcg/kg SC daily (Ruiz de Gopegui and Feldman 2000)
- b) For neutropenia: 1–5 mcg/kg SC daily (Ritt and Modiano 1999)

■ CATS:

- a) For neutropenia secondary to drug toxicity, infectious diseases, FeLV-associated cyclic neutropenia or idiopathic causes: 5 mcg/kg SC twice daily. Cost and/or development of

antibodies usually limit usefulness to a few weeks, but often it is effective for acute or life-threatening neutropenia. (Levy 2000)

- b) For neutropenia: 1–5 mcg/kg SC daily (Ritt and Modiano 1999)
- c) For adjunctive therapy of neutropenia: 5 mcg/kg SC daily until neutrophil count exceeds 3,000/mcl for 2 days (Levy 2002)

Monitoring

- CBC with platelets, routinely

Client Information

- Clients should be briefed on the cost of this agent as well as the possibility that it may cause antibodies to form against endogenously produced G-CSF, thereby causing a potentially life threatening neutropenia.

Chemistry/Synonyms

Prepared via recombinant DNA technology from human DNA, filgrastim is a single chain polypeptide containing 175 amino acids with a molecular weight of about 18,800 daltons. The commercially available injection occurs as a clear solution; buffered to a pH of 4.

Filgrastim may also be known as: granulocyte colony-stimulating factor, G-CSF, recombinant methionyl human GCS-F, r-metHuG-CSF, *Filgen*®, *Gran*®, *Granulen*®, *Granulokine*®, *Neulasta*®, *Neupogen*®, and *Neutromax*®.

Storage/Stability/Compatibility

Injection should be stored in the refrigerator (2–8°C). Do not freeze or shake contents of vial. The drug should never be diluted with saline as a precipitate may form. If necessary it may be diluted into 5% dextrose for injection, but if diluted to concentrations between 5 and 15 mcg/mL, it is recommended that albumin be added to the solution to a concentration of 2 mg/mL to reduce adsorption to plastic IV tubing. It is not recommended to dilute to a concentration of less than 5 mcg/mL.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Filgrastim Injection: 300 mcg/mL preservative free in 1 mL and 1.6 mL single dose vials; 300 mcg/0.5 mL preservative free in 0.5 mL and 0.8 mL prefilled syringes; *Neupogen*® (Amgen); (Rx)

FINASTERIDE

(fin-as-te-ride) Proscar®, Propecia®

5-ALPHA-REDUCTASE INHIBITOR

Prescriber Highlights

- 5-alpha-reductase inhibitor potentially useful for dogs with benign prostatic hypertrophy & ferrets with adrenal disease
- Contraindications: Hypersensitivity to finasteride; sexually developing animals
- Caution: Patients with significant hepatic impairment
- Adverse Effects: Potentially may cause some minor sexual side effects
- Expense may be an issue

Uses/Indications

Finasteride may be useful in treating the benign prostatic hypertrophy in canine patients. Because of the drug's relative expense and the long duration of therapy required to see a response, its usefulness may be limited in veterinary medicine.

It may also be useful in the adjunctive treatment of adrenal disease in ferrets.

Pharmacology/Actions

Finasteride specifically and totally inhibits 5-alpha-reductase. This enzyme is responsible for metabolizing testosterone to dihydrotestosterone (DHT) in the prostate, liver and skin. DHT is a potent androgen and is the primary hormone responsible for the development of the prostate.

Pharmacokinetics

Finasteride is absorbed after oral administration and in humans about 65% is bioavailable. The presence of food does not affect absorption. It is distributed across the blood-brain barrier and is found in seminal fluid. In humans, about 90% is bound to plasma proteins. Finasteride is metabolized in the liver and the half-life is about 6 hours. Metabolites are excreted in the urine and feces. In humans, a single daily dose suppresses DHT concentrations for 24 hours.

Contraindications/Precautions/Warnings

Finasteride is contraindicated in patients hypersensitive to it. It should be used with caution in patients with significant hepatic impairment as metabolism of the drug may be reduced. Finasteride should be used in males only; do not use in sexually developing animals.

Adverse Effects

One study done in dogs reported no adverse effects or irreversibility of effects after treating for 21 weeks at 1 mg/kg. The adverse effects reported in humans have been very limited, mild and transient. Decreased libido, decreased ejaculate volume, and impotence have been reported.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **X** for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*)

Finasteride is not indicated for use in females. It is not known whether finasteride is excreted in milk.

Overdosage/Acute Toxicity

Limited information is available; gastrointestinal effects may be noted.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving finasteride and may be of significance in veterinary patients:

- **ANTICHOLINERGIC DRUGS:** May precipitate or aggravate urinary retention thereby negating the effects of the drug when used for BPH

Doses■ **DOGS:**

- a) For benign prostatic hyperplasia: 0.1–0.5 mg/kg once daily PO; for a 10–50 kg dog, one 5 mg tablet daily (Root Kustritz and Klausner 2000); (Kamolpatana, Johnston et al. 1998), (Bartges 2006c)
- b) For dogs <15 kg: 1.5 mg (approx. 1/3 of a 5 mg tablet); for dogs 15–30 kg = 2.5 mg (1/2 tablet); for dogs >30 kg = 5 mg (one tablet). Given PO daily. (Romagnoli 2006b)

■ **FERRETS:**

- a) For adjunctive treatment of adrenal disease: 5 mg (total dose) tablet once daily (Johnson 2006b)

Monitoring

- Efficacy: Prostate exam

Client Information

- Clients should understand that therapy might be prolonged before efficacy can be determined and regular dosing compliance is mandatory. Once the drug is stopped, the prostate will start growing again.
- Pregnant women should be advised to guard against exposure to this drug as it may cause birth defects.

Chemistry/Synonyms

Finasteride is a 4-azasteroid synthetic drug that inhibits 5 alpha-dihydroreductase (DH), and has a molecular weight of 372.55.

Finasteride may also be known as: finasteridum, MK-0906, and MK-906; many trade names are available.

Storage/Stability

Store tablets below 30°C in tight containers and protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Finasteride Oral Tablets: 1 mg and 5 mg; *Proscar*®, *Propecia*® (Merck); generic; (Rx)

Fipronil—See the listing in the Dermatological Agents, Topical Appendix

FIROCOXIB

(feer-oh-koks-ib) Previcox®, Equioxx®

ORAL COX-2 INHIBITOR NSAID

Prescriber Highlights

- Oral COX-2 NSAID labeled for the control of pain & inflammation associated with osteoarthritis in dogs & horses
- Adverse effect profile not fully determined; in DOGS: GI effects (vomiting, anorexia) most likely, but serious effects are possible
- Adverse effects in HORSES include mouth ulcers, facial skin lesions, excitation (rare)

Uses/Indications

Firocoxib is indicated in dogs and horses for the control of pain and inflammation associated with osteoarthritis. A chewable tablet form for dogs and an oral paste for horses are available.

Like other NSAIDs, firocoxib can be useful for treating fever, pain, and/or inflammation associated with other conditions, post-surgery, trauma, etc.

Firocoxib may also be useful in other species, but information is scant regarding its safety and efficacy. One study in cats (McCann, Rickes et al. 2005) evaluating firocoxib in experimentally induced pyrexia, demonstrated that the drug was effective after a single oral dose in preventing or attenuating pyrexia at all doses studied (0.75–3 mg/kg).

Pharmacology/Actions

Firocoxib is a coxib-class, nonsteroidal antiinflammatory drug (NSAID). It is believed to predominantly inhibit cyclooxygenase-2 (COX-2) and spare COX-1 at therapeutic dosages. This theoretically would inhibit production of the prostaglandins that contribute to pain and inflammation (COX-2) and spare those that maintain normal gastrointestinal, platelet and renal function (COX-1). However, COX-1 and COX-2 inhibition studies are done *in vitro* and do not necessarily correlate perfectly with clinical effects seen in actual patients.

Pharmacokinetics

In dogs, firocoxib absorption after oral dosing varies among individuals. Oral bioavailability with the chewable tablets, on average, is about 38%. Food will delay, but not affect the amount absorbed. Peak levels occur about 1 hour after dosing if fasted, and 5 hours if the patient is fed. Volume of distribution at steady state is about 3 L/kg; it is 96% bound to plasma proteins. Biotransformation occurs predominantly via dealkylation and glucuronidation in the liver; elimination is principally in the bile and feces. Elimination half-life in dogs is approximately 6–8 hours.

In horses, oral availability after administering the paste is approximately 79%. Peak levels occur 4–12 hours after dosing. Volume of distribution at steady state is about 1.7 L/kg and it is 98% bound to plasma proteins. Biotransformation in horses occurs primarily via decyclopropylmethylation and then glucuronidation. Metabolites are primarily excreted in the urine. Elimination half-life is approximately 30–40 hours.

Pharmacokinetics of firocoxib have only been reported in two cats studied (McCann, Rickes et al. 2005). Oral bioavailability after administering an oral suspension was about 60% and the volume of distribution, between 2–3 L/kg. Elimination half-life in the two cats studied averaged about 10 hours.

Contraindications/Precautions/Warnings

Firocoxib should not be used in animals hypersensitive to it or other NSAIDs. The drug should be used with caution and enhanced monitoring in patients with preexisting renal, hepatic or cardiovascular dysfunction, and those that are dehydrated, hypovolemic, hypotensive, or on concomitant diuretic therapy. Because geriatric patients have reduced renal function and firocoxib is often used for osteoarthritis in this patient population, ongoing monitoring for adverse effects is mandatory.

Because all NSAIDs can potentially cause GI toxicity, firocoxib is relatively contraindicated in dogs with active GI ulcerative conditions. As it may affect platelet function, it is relatively contraindicated in patients with bleeding disorders or thrombocytopenia.

The safety of firocoxib in horses less than one year old has not been established.

A chronic dosing (5 mg/kg for 6 months) study performed in puppies 10–13 weeks old, showed subclinical periportal hepatic

fatty changes in half the dogs studied. Higher doses (15–25 mg/kg; 3–5X) in this age range caused increased rates of hepatic fatty changes; some dogs died or were euthanized due to moribund conditions. The manufacturer states in the package insert: “Use of this product at doses above the recommended 5 mg/kg in puppies less than 7 months old has been associated with serious adverse reactions, including death” and “...this product cannot be accurately dosed in dogs weighing less than seven pounds in body weight.” The labeling in the UK states that it should not be used in dogs “less than 10 weeks of age.”

If changing from one NSAID to another in dogs for reasons of efficacy, consider a washout period between agents. While the actual length of time between agents is controversial and opinions vary widely, often a 24-hour washout period between COX-2 selective agents is recommended. Recommendations for washout periods before starting a COX-2 selective agent after using a non-selective agent or aspirin are usually much longer (72 hours–1 week).

Adverse Effects

Because firocoxib is a relatively new product, its adverse effect profile in dogs is yet to be fully determined. In pre-approval studies (128 dogs treated), vomiting and decreased appetite/anorexia were the most common adverse effects noted with an approximate incidence rate of 4% and 2%, respectively.

In the FDA's CVM Cumulative Adverse Drug Experiences (ADE) Summaries Report (through 12/06/2006) for firocoxib in dogs, the most prevalent ADE reported was vomiting. On the list of 10 most reported ADE's for firocoxib, the second most reported event was anorexia. Other effects on this list included: diarrhea, increases in BUN, creatinine, alkaline phosphatase and ALT, depression/lethargy, and ataxia. Melena, GI ulcers, bloody vomiting and GI perforation were included within the 25 most reported events listed. It should be noted that this data reflects voluntary reporting to the FDA and does not reflect actual incidence rates, nor is causation necessarily proven.

In pre-approval studies done in horses treated for 14 days, diarrhea/loose stools were seen in about 2%. Excitation was rarely (<1%) detected. In safety studies, oral lesions/ulcers were seen in some horses after dosages of 1–5X were given.

Reproductive/Nursing Safety

Information on the safety of firocoxib in breeding, pregnant or lactating dogs or horses is not available. Studies performed in pregnant rabbits at dosages approximating those given to dogs, demonstrated maternotoxic and fetotoxic effects.

Overdosage/Acute Toxicity

Limited information is available for acute overdoses in animals. The reported oral LD₅₀ for rats is > 2 grams per kg. Should an overdose occur, contacting an animal poison control center or the manufacturer (1-877-217-3543) is highly recommended. Use of gut emptying protocols and supportive treatment (IV fluids, oral sucralfate, etc.) may be useful in managing the case.

Drug Interactions

In the package insert for *Previcox*, the manufacturer states the following (**Note: bold mine—Plumb**): “As a class, cyclooxygenase inhibitory NSAIDs may be associated with renal and gastrointestinal toxicity. Sensitivity to drug-associated adverse events varies with the individual patient. Patients at greatest risk for renal toxicity are those that are dehydrated, on concomitant **diuretic therapy**, or those with existing renal, cardiovascular, and/or hepatic dysfunction. Concurrent administration of **potentially nephrotoxic drugs** should be carefully approached. NSAIDs may inhibit the prostaglandins that maintain normal homeostatic function. Such antiprostaglan-

din effects may result in clinically significant disease in patients with underlying or pre-existing disease that has not been previously diagnosed. Since many NSAIDs possess the potential to produce gastrointestinal ulcerations, concomitant use with other antiinflammatory drugs, such as **NSAIDs** or **corticosteroids**, should be avoided or closely monitored. The concomitant use of **protein bound drugs** with PREVICOX™ Chewable Tablets has not been studied in dogs. Commonly used **protein-bound drugs** include cardiac, anticonvulsant, and behavioral medications. The influence of concomitant drugs that may inhibit the metabolism of PREVICOX™ Chewable Tablets has not been evaluated."

Drug interactions reported in humans taking NSAIDs, that may be of significance in veterinary patients receiving firocoxib include:

- **ACE INHIBITORS** (e.g., **enalapril**, **benazepril**): Some NSAIDs can reduce effects on blood pressure
- **ASPIRIN**: May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- **CORTICOSTEROIDS** (e.g., **prednisone**): May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- **DIGOXIN**: NSAIDs may increase serum levels
- **FLUCONAZOLE**: Administration has increased plasma levels of celecoxib in humans and potentially could also affect firocoxib levels in dogs
- **FUROSEMIDE**: NSAIDs may reduce the saluretic and diuretic effects
- **HIGHLY PROTEIN BOUND DRUGS** (**phenytoin**, **valproic acid**, **oral anticoagulants**, **other antiinflammatory agents**, **salicylates**, **sulfonamides**, **sulfonylurea antidiabetic agents**): As firocoxib is highly bound to plasma proteins (95–98%), it may displace other highly bound drugs or these agents could displace firocoxib. Increased serum levels, duration of actions and toxicity could occur.
- **METHOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with **methotrexate**; use together with extreme caution
- **NEPHROTOXIC DRUGS** (e.g., **furosemide**, **aminoglycosides**, **amphotericin B**, etc.): May enhance the risk of nephrotoxicity development

Laboratory Considerations

No specific laboratory concerns; see Monitoring

Doses

■ DOGS:

For the control of pain and inflammation associated with osteoarthritis (labeled indication):

- a) 5 mg/kg (2.27 mg/lb) PO once daily. Dosage should be calculated in half tablet increments and can be administered with or without food. (Package insert; *Previcox*®—Merial)

■ CATS:

Caution: While firocoxib may ultimately be shown to be safe for use in cats, supporting information (or FDA approval) is not currently available for it to be recommended.

■ HORSES:

For the control of pain and inflammation associated with osteoarthritis (labeled indication):

- a) 0.1 mg/kg (0.45 mg/lb) body weight PO daily for up to 14 days (Package insert; *Equioxx*®—Merial)

Monitoring

- Baseline and periodic physical exam including clinical efficacy and adverse effect queries
- Baseline and periodic: CBC, liver function, renal function, and electrolytes; urinalysis

Client Information

- The manufacturer provides a client hand-out that is recommended to be distributed each time the drug is dispensed
- May be administered with or without food
- Contact veterinarian if any of the following occur in dogs: vomiting, decreased appetite/weight loss, diarrhea or loose stools, changes in behavior or activity, changes in water consumption or urination, or yellowing of whites of eyes or mucous membranes
- For horses, contact veterinarian if patient develops ulcers or sores on tongue or in mouth, sores or lesions on facial skin or lips, diarrhea/loose stools, changes in behavior/activity, changes in feed or water consumption, or yellowing of whites of eyes or mucous membranes

Chemistry/Synonyms

Firocoxib occurs a white crystalline powder.

Firocoxib may also be known as: 3-(cyclopropylmethoxy)-5, 5-dimethyl-4-(4-methylsulfonyl) phenylfuran-2(5H)-on or ML-1,785,713, *Equioxx*®, and *Previcox*®.

Storage/Stability/Compatibility

Commercially available tablets and oral paste should be stored at room temperature (15–30°C); brief excursions are permitted up to 40°C (104°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Firocoxib Chewable Tablets (scored): 57 mg, & 227 mg; *Previcox*® (Merial); (Rx). Approved for use in dogs.

Firocoxib Oral Paste: 0.82% w/w (8.2 mg firocoxib per gram of paste) in a 6.93 gram oral syringe (total of 56.8 mg of firocoxib per syringe); *Equioxx*® (Merial); (Rx).

HUMAN-LABELED PRODUCTS: None

Fish Oil—See Fatty Acids

FLAVOXATE HCL

(fla-vox-ate) Urispas®

PARASYMPATHETIC BLOCKER; URINARY ANTISPASMODIC

Prescriber Highlights

- Alternative medication to treat with detrusor hyper-spasticity (hyperactive bladder; urge incontinence) in dogs
- Not commonly used; little information available on veterinary use
- Most likely adverse effect is weakness

Uses/Indications

Flovoxate may be considered for treating dogs with detrusor hyper-spasticity (hyperactive bladder, urge incontinence).

Pharmacology/Actions

Flavoxate has direct smooth muscle relaxing properties and anti-muscarinic effects.

Pharmacokinetics

No information was located for dogs or cats. In humans, the drug's onset of action is within an hour with peak effects at around 2 hours post dose. 57% of a dose is excreted in the urine within 24 hours.

Contraindications/Precautions/Warnings

Flavoxate is contraindicated in human patients with pyloric or duodenal obstruction, obstructive intestinal lesions or ileus, achalasia, GI hemorrhage or obstructive uropathies of the lower urinary tract. It is to be given with caution in patients with suspected glaucoma.

Adverse Effects

Weakness is the most likely adverse effect seen in dogs treated with flavoxate.

Reproductive/Nursing Safety

In laboratory animals, doses of up to 34X (human dose) demonstrated no harm to fetuses or impaired fertility. In humans, glucagon is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether this drug is excreted into milk. Use with caution in nursing mothers.

Overdosage/Acute Toxicity

The approximate oral LD-50 for rats and mice are 4300 mg/kg and 1800 mg/kg respectively.

Drug Interactions

No significant drug interactions with flavoxate were located; however, concomitant use with other **anticholinergic drugs** may cause additive effects.

Laboratory Considerations

No concerns noted

Doses

■ DOGS:

To decrease urinary bladder contractility:

- a) 100–200 mg (per dog) PO q6–8h (Bartges 2006a)

Monitoring

- Clinical efficacy
- Adverse effects (most likely GI)
- Consider occasional CBC's and creatinine to monitor for neutropenia or renal dysfunction if using the drug chronically

Client Information

- May cause weakness or changes in activity level in treated dogs; if these become a problem, contact veterinarian

Chemistry/Synonyms

Flavoxate HCl occurs as a white or almost white crystalline powder. It is slightly soluble in water or alcohol.

Flavoxate may also be known as flavoxato, AK 123, or Rec 7-0040. A common trade name is *Urispas*®.

Storage/Stability

Flavoxate tablets should be stored at room temperature (15–30°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Flavoxate HCl Tablets (film-coated) 100 mg: *Urispas*® (Ortho-McNeil), generic (Global); (Rx)

FLORFENICOL

(flor-fen-i-col) NuFlor®

ANTIBIOTIC

Prescriber Highlights

- Broad spectrum antibiotic approved for use in cattle, swine, & fish, but may be useful in other species (e.g., dogs, cats)
- Contraindications: Do not give IV, to veal calves or cattle of breeding age (per manufacturer)
- Adverse Effects: Cattle: Anorexia, decreased water consumption, diarrhea, injection site reactions (may result in trim loss); IM injection may be painful in small animals
- Slaughter withdrawals depend upon route of administration (IM shorter than SC)

Uses/Indications

The drug is approved for use in cattle only (in the USA) for the treatment of bovine respiratory disease (BRD) associated with *Pasteurella haemolytica*, *Pasteurella multocida*, and *Haemophilus somnus*.

Because florfenicol has activity against a wide range of microorganisms (e.g., *Mycoplasma*), it may be useful for treating other infections in cattle (or other species) as well, but specific data is limited.

Pharmacology/Actions

Like chloramphenicol, florfenicol is a broad-spectrum antibiotic that has activity against many bacteria. It acts by binding to the 50S ribosome, thereby inhibiting bacterial protein synthesis.

Pharmacokinetics

After IM injection in cattle, approximately 79% of the dose is bioavailable. The drug appears to be well distributed throughout the body, including achievement of therapeutic levels in the CSF. In cattle, the volume of distribution is about 0.7 L/kg and only about 13% is bound to serum proteins. Mean serum half-life is 18 hours, but wide interpatient variation exists.

In dogs, florfenicol is absorbed poorly after subcutaneous injection and has an elimination half-life of less than 5 hours. PO administration results in good bioavailability (95%), but is eliminated rapidly (elimination half-life 1.25 hours).

Cats, however, have high absorption of a 100 mg/mL solution when either given IM or orally and have an elimination half-life of less than 5 hours. Times above an MIC of 2 mg/mL were 12 hours (IM) and 18 hours (PO); and an MIC of 8 mg/mL were 10 hours (IM) and 6 hours (PO), respectively, in cats.

Contraindications/Precautions/Warnings

No contraindications are listed in the package insert, but see residue warnings (in Dosage forms) and reproductive safety (below).

Caution: Do not give this drug IV.

Adverse Effects

Noted transient adverse reactions in cattle include anorexia, decreased water consumption, or diarrhea. Injection site reactions can occur that may result in trim loss. Reactions may be more severe if injected at sites other than the neck.

When used in other species (mammals), gastrointestinal effects, including severe diarrheas are potentially possible.

Reproductive/Nursing Safety

Safety or effects when used in breeding cattle or swine, during pregnancy, or during lactation are unknown and the manufacturer states that the drug is not for use in cattle of breeding age or in swine intended for breeding.

Overdosage/Acute Toxicity

In toxicology studies where feeder calves were injected with up to 10X the recommended dosage, the adverse effects noted above were seen, plus increased serum enzymes. These effects were generally transient in nature. Long-term (43 day) standard dosage studies showed a transient decrease in feed consumption, but no long-term negative effects were noted.

Drug Interactions

No specific drug interactions for florfenicol were located, but the drug may behave similarly to chloramphenicol. If so, florfenicol could antagonize the bactericidal activity of the **penicillins** or **aminoglycosides**. This antagonism has not been demonstrated *in vivo*, and these drug combinations have been used successfully many times clinically. Other antibiotics that bind to the 50S ribosomal subunit of susceptible bacteria (**erythromycin**, **clindamycin**, **lincomycin**, **tylosin**, etc.) may potentially antagonize the activity of chloramphenicol or vice versa, but the clinical significance of this potential interaction has not been determined. For other drug interactions that florfenicol may share with chloramphenicol, see the monograph for chloramphenicol or refer to other drug information resources.

Doses

■ CATTLE:

- a) For treatment of BRD: 20 mg/kg IM (in neck muscle only); repeat in 48 hours. Alternatively, a single 40 mg/kg SC dose (in neck) may be used. **Note:** 20 mg/kg equates to 3 mL of the injection per 100 lb. of body weight. Do not exceed 10 mL per injection site. (Package Insert; *Nuflor*® —Schering Plough)

■ DOGS:

- a) For susceptible systemic (bacterial or rickettsial) infections when myelotoxic potential (in humans or animals) of chloramphenicol is to be avoided: 20 mg/kg IM q8h for 3–5 days. (Greene, Hartmann et al. 2006)

■ CATS:

- a) For susceptible systemic infections (bacterial or rickettsial) infections when myelotoxic potential (in humans or animals) of chloramphenicol is to be avoided: 22 mg/kg IM, PO q12h for 3–5 days (**Note:** Oral dosage form not available, but solution given orally to experimental cats was well absorbed) (Greene, Hartmann et al. 2006)

■ SHEEP & GOATS:

- a) For respiratory disease complex in kids: 20 mg/kg a day (route not specified; assume IM) for 2 days (de la Concha 2002)

■ SWINE:

- a) For swine respiratory disease: In water at a concentration of 400 mg/gallon (100 ppm). Use as only source of drinking water for 5 days. For bulk tank add one gallon concentrate to 128 gallons of water; for proportioner set to 1:128 (0.8%). (Label information; *NuFlor*® Concentrate Solution—Schering-Plough)

Monitoring

- Clinical efficacy
- Injection site reactions

Client Information

- Residue Warnings: When administered as labeled, cattle slaughter withdrawal is 28 days post injection if using the IM route; 38 days after the SC route. Swine (in drinking water) = 16 days.
- Not to be used in female dairy cattle 20 months of age or older.
- A withdrawal period has not been established in preruminating calves. Do not use in calves to be processed for veal.
- Do not give IV.

Chemistry/Synonyms

A fluorinated analog of thiamphenicol, florfenicol is commercially available as light yellow to straw-colored injectable solution also containing n-ethyl-2-pyrrolidone, propylene glycol, and polyethylene glycol.

Florfenicol may also be known as Sch-25298 and *NuFlor*®.

Storage/Stability

Florfenicol injection should be stored between 2°–30°C (36°–86°F). The oral solution (swine) should be stored between 2°–26°C (36°–77°F)

Dosage Forms/Regulatory Status/Withdrawal Times

VETERINARY-LABELED PRODUCTS:

Florfenicol Injection: 300 mg/mL in 100 mL, 250 mL and 500 mL multi-dose vials; *NuFlor*® (Schering-Plough); (Rx). Approved for use in cattle; see residue warnings above. Slaughter withdrawal (at labeled dosages) = 28 days (IM treatment), 38 days (subcutaneous treatment). Do not use in female dairy cattle 20 months of age or older. A withdrawal period has not been established in preruminating calves. Do not use in calves to be processed for veal.

Florfenicol 2.3% (23 mg/mL) Concentrate Solution in 2.2 btl; *NuFlor*® Concentrate Solution (Schering-Plough); (Rx). Approved for use in swine; Slaughter withdrawal (at labeled dosages) = 16 days.

There are florfenicol products for addition to catfish or salmonid feeds (*Aquaflor*®) and to feed for swine.

HUMAN-LABELED PRODUCTS: None

FLUCONAZOLE

(floo-kon-a-zole) Diflucan®

ANTIFUNGAL

Prescriber Highlights

- ▶ Oral or parenteral antifungal particularly useful for CNS infections
- ▶ **Caution:** Renal failure (dosage adjustment needed), pregnancy (safety not established), hepatic failure
- ▶ **Adverse Effects:** Occasional GI effects (inappetence) in cats or dogs; in humans: headache &, rarely, increased liver enzymes & hepatic toxicity
- ▶ **Expensive**, but price is decreasing now that it is available as a generic
- ▶ **Drug Interactions**

Uses/Indications

Fluconazole may have use in veterinary medicine in the treatment of systemic mycoses, including cryptococcal meningitis, blastomycosis, and histoplasmosis. It may also be useful for superficial candidiasis or dermatophytosis. Because of the drug's unique pharmacokinetic qualities, it is probably more useful in treating CNS infections or fungal urinary tract infections than other azole derivatives. Fluconazole does not have appreciable effects (unlike ketoconazole) on hormone synthesis and may have fewer side effects than ketoconazole in small animals.

Pharmacology/Actions

Fluconazole is a fungistatic triazole compound. Triazole-derivative agents, like the imidazoles (clotrimazole, ketoconazole, etc.), presumably act by altering the cellular membranes of susceptible fungi, thereby increasing membrane permeability and allowing leakage of cellular contents and impaired uptake of purine and pyrimidine precursors. Fluconazole has efficacy against a variety of pathogenic fungi including yeasts and dermatophytes. *In vivo* studies using laboratory models have shown that fluconazole has fungistatic activity against some strains of *Candida*, *Cryptococcus*, *Histoplasma*, and *Blastomyces*. *In vivo* studies of efficacy against *Aspergillus* strains have been conflicting.

Pharmacokinetics

Fluconazole is rapidly and nearly completely absorbed (90%) after oral administration. Gastric pH or the presence of food, do not appreciably alter fluconazole's oral bioavailability. It has low protein binding and is widely distributed throughout the body and penetrates well into the CSF, eye, and peritoneal fluid. Fluconazole is eliminated primarily via the kidneys and achieves high concentrations in the urine. In humans, fluconazole's serum half-life is about 30 hours in patients with normal renal function. Because of its long half-life, fluconazole does not reach steady state plasma levels for 6–14 days after beginning therapy, unless loading doses are given. Patients with impaired renal function may have half-lives extended significantly and dosage adjustment may be required.

Contraindications/Precautions/Warnings

Fluconazole should not be used in patients hypersensitive to it or other azole antifungal agents. In patients with hepatic impairment it should be used only when the potential benefits outweigh the risks. Because fluconazole is eliminated primarily by the kidneys,

fluconazole doses or dosing intervals may need to be adjusted in patients with renal impairment.

Fluconazole is reportedly toxic to budgerigars.

Adverse Effects

There is limited experience with this drug in domestic animals. Thus far, it appears to be safe to use in dogs and cats. Occasionally, inappetence may be reported.

In humans, the side effects have been generally limited to occasional GI effects (vomiting, diarrhea, anorexia/nausea) and headache. Rarely, increased liver enzymes and hepatic toxicity, exfoliative skin disorders, and thrombocytopenia have been reported in humans. Thrombocytopenia has not been reported thus far in animals.

Reproductive/Nursing Safety

Safety during pregnancy has not been established and it is not recommended for use in pregnant animals unless the benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Fluconazole is excreted in milk at concentrations similar to plasma. Use with caution in nursing dams.

Overdosage/Acute Toxicity

There is very limited information on the acute toxicity of fluconazole. Rats and mice survived doses of 1 g/kg, but died within several days after receiving 1–2 g/kg. Rats and mice receiving very high dosages demonstrated respiratory depression, salivation, lacrimation, urinary incontinence, and cyanosis. If a massive overdose occurs, consider gut emptying and give supportive therapy as required. Fluconazole may be removed by hemodialysis or peritoneal dialysis.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fluconazole and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Lab animal studies have shown that fluconazole used concomitantly with amphotericin B may be antagonistic against *Aspergillus* or *Candida*; the clinical importance of these findings is not yet clear
- **BUSPIRONE:** Plasma concentrations may be elevated
- **CISAPRIDE:** Fluconazole may increase cisapride levels and the possibility for toxicity
- **CORTICOSTEROIDS:** Fluconazole may inhibit the metabolism of corticosteroid; potential for increased adverse effects
- **CYCLOPHOSPHAMIDE:** Fluconazole may inhibit the metabolism of cyclophosphamide and its metabolites; potential for increased toxicity
- **CYCLOSPORINE:** Increased cyclosporine levels
- **DIURETICS, THIAZIDES:** Increased fluconazole concentrations
- **FENTANYL/ALFENTANIL:** Fluconazole may increase fentanyl levels
- **MIDAZOLAM:** Increased midazolam levels and effects
- **NSAIDs:** Fluconazole may increase plasma levels; increased risk for adverse effects
- **RIFAMPIN:** May decrease fluconazole efficacy; fluconazole may increase rifampin levels
- **THEOPHYLLINE/AMINOPHYLLINE:** Increased theophylline concentrations

- **TRICYCLIC ANTIDEPRESSANTS** (**clomipramine**, **amitriptyline**, etc.): Fluconazole may exacerbate the effects of tricyclic antidepressants
- **SULFONYLUREA ANTIDIABETIC AGENTS** (e.g., **glipizide**, **glyburide**): Fluconazole may increase levels; hypoglycemia possible
- **VINCISTINE/VINBLASTINE**: Fluconazole may inhibit vinca alkaloid metabolism
- **WARFARIN**: Fluconazole may cause increased prothrombin times in patients receiving warfarin or other coumarin anticoagulants

Doses

■ DOGS:

- a) General dosing guidelines: Give twice calculated daily dose for the first day of treatment; give for 2–3 days if rapidly advancing or severe disseminated mycosis. Give IV solution over 1–2 hours.
For cryptococcosis, candidiasis, systemic mycoses, nasal aspergillosis: 2.5–5 mg/kg PO or IV q12–24h for 56–84 days. Often treat neurologic ocular cryptococcosis for at least 12 weeks or 2 weeks after CSF exam shows resolution of inflammation and antigen test results on serum and CSF are negative.
For fungal meningitis: 5–8 mg/kg PO or IV q12h OR 8–12 mg/kg PO or IV once daily (q24h) for 56–84 days;
For urinary candidiasis: 5–10 mg/kg PO q24h for 21–42 days;
For urinary *Candida glabrata* infection: 12 mg/kg PO once daily for 21–42 days. (Greene, Hartmann et al. 2006)
- b) For cryptococcosis: 5 mg/kg PO once or twice daily. Treatment should continue for at least 2 months beyond resolution of clinical signs. (Taboada 2000)
- c) For blastomycosis: 5 mg/kg PO q12h for 60 days
For cryptococcosis: 5–15 mg/kg PO q12–24h for 6–10 months (Lemarie 2003b)
- d) For treatment of *Malassezia* (may be safer than itraconazole or ketoconazole in dogs with hepatic disease): 5 mg/kg PO once daily. (Thomas 2005b)
- e) For systemic treatment of *Malassezia* dermatitis: 5–10 mg/kg PO once daily to once a week. (Ihrke 2006)
- f) For systemic treatment of *Malassezia* dermatitis: 2–5 mg/kg PO once daily (q24h). (Beale and Murphy 2006)

■ CATS:

- a) General dosing guidelines: Give twice calculated daily dose for the first day of treatment; give for 2–3 days if rapidly advancing or severe disseminated mycosis. For cryptococcosis or other systemic infections, treatment should continue until antigen testing results of blood or CSF are negative, this is usually at least 2 months beyond clinical resolution (mean time of 8 months treatment).
For nasal or dermal cryptococcosis: 5–10 mg/kg PO q12–24h, or 10 mg/kg PO q24h; for most infections, 50 mg/cat PO once daily achieves adequate therapeutic levels.
For CNS, intraocular, or multisystemic cryptococcosis: 50–100 mg/cat PO or IV q12h. Often treat neurologic ocular cryptococcosis for at least 12 weeks or 2 weeks after CSF exam shows resolution of inflammation and antigen test results on serum and CSF are negative.
For CNS, intraocular or multisystemic mycoses: 50 mg/cat PO once daily (q24h); (Greene, Hartmann et al. 2006)
- b) For cryptococcosis: 50 mg PO twice daily. Treatment should continue for 1 month beyond resolution of clinical signs. (Legendre 1995)

- c) For cryptococcosis: 50 mg PO twice daily. Treatment should continue for at least 2 months beyond resolution of clinical signs. (Taboada 2000)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: 25–43 mg/kg slow IV q12h (Ivey and Morrissey 2000)

■ BIRDS:

- a) As an alternate treatment of aspergillosis: 5–10 mg/kg PO once daily for up to 6 weeks, with or after amphotericin B (Oglesbee and Bishop 1994)

Monitoring

- Clinical Efficacy
- With long-term therapy, occasional liver function tests are recommended

Client Information

- Cost of this drug may be an issue. Fluconazole therapy may be prolonged (several weeks to months) and an average dosage in a cat (50 mg twice a day) may be very expensive
- Compliance with treatment recommendations must be stressed.
- Have clients report any potential adverse effects.

Chemistry/Synonyms

A synthetic triazole antifungal agent, fluconazole occurs as a white crystalline powder. It is slightly soluble (8 mg/mL) in water.

Fluconazole may also be known as UK-49858; many trade names are available.

Storage/Stability/Compatibility

Fluconazole tablets should be stored at temperatures less than 30°C in tight containers. Fluconazole injection should be stored at temperatures from 5–30°C (5–25°C for the *Viaflex*® bags); avoid freezing. Do not add additives to the injection.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Fluconazole Tablets: 50 mg, 100 mg, 150 mg, & 200 mg; *Diflucan*® (Pfizer); generic; (Rx)

Fluconazole Powder for Oral Suspension: 10 mg/mL & 40 mg/mL (when reconstituted) in 35 mL; *Diflucan*® (Roerig); (Rx)

Fluconazole Injection: 2 mg/mL in 100 mL or 200 mL bottles or *Viaflex Plus* (available with sodium chloride or dextrose diluents); *Diflucan*® (Pfizer); generic; (Rx)

FLUCYTOSINE

(floo-sye-toe-seen) Ancobon®

ANTIFUNGAL

Prescriber Highlights

- ▶ Antifungal used in combination (to reduce resistance development)
- ▶ Contraindicated in patients hypersensitive to it
- ▶ Extreme Caution: Renal impairment, preexisting bone marrow depression, hematologic diseases, or receiving other bone marrow suppressant drugs
- ▶ Caution: Hepatic disease
- ▶ Adverse Effects: Most common: GI disturbances; Potentially: dose dependent bone marrow depression, cutaneous eruption & rash primarily seen on the scrotum & nasal planum (in dogs), oral ulceration, increased hepatic enzymes, CNS effects in cats
- ▶ Dogs may not tolerate therapy for more than 10–14 days
- ▶ Teratogenic in rats

Uses/Indications

Flucytosine is principally active against strains of *Cryptococcus* and *Candida*. When used alone, resistance can develop quite rapidly to flucytosine, particularly with *Cryptococcus*. Because it penetrates relatively well into the CNS, it has been used in combination for the treatment of CNS cryptococcosis. Some cases of subcutaneous and systemic chromoblastosis may also respond to flucytosine. The drug can have synergistic efficacy when used with amphotericin B. Clinically, it is used primarily with amphotericin B in the treatment of cryptococcosis.

Pharmacology/Actions

Flucytosine penetrates fungal cells where it is deaminated by cytosine deaminase to fluorouracil. Fluorouracil acts as an antimetabolite by competing with uracil, thereby interfering with pyrimidine metabolism and eventually RNA and protein synthesis. It is thought that flucytosine is converted to fluorodeoxyuridylic acid that inhibits thymidylate synthesis and ultimately DNA synthesis.

In human cells, cytosine deaminase is apparently not present or only has minimal activity. Rats apparently metabolize some of the drug to fluorouracil, which may explain the teratogenic effects seen in this species. It is unclear how much cytosine deaminase activity dog and cat cells possess.

Pharmacokinetics

Flucytosine is well absorbed after oral administration. The rate, but not extent, of absorption will be decreased if given with food.

Flucytosine is distributed widely throughout the body. CSF concentrations may be 60–100% of those found in the serum. In healthy humans, the volume of distribution is about 0.7 L/kg. Only about 2–4% of the drug is bound to plasma proteins. It is unknown if flucytosine is distributed into milk.

Absorbed flucytosine is excreted basically unchanged in the urine via glomerular filtration. In humans, the half-life is about 3–6 hours in patients with normal renal function, but may be significantly prolonged in patients with renal dysfunction.

Contraindications/Precautions/Warnings

Flucytosine is contraindicated in patients hypersensitive to it.

Flucytosine should be used with extreme caution in patients with renal impairment. Some clinicians recommend monitoring serum flucytosine levels in these patients and adjusting dosage (or dosing interval) to maintain serum levels at less than 100 micrograms/mL. One clinician (Macy, 1987) recommends dividing the flucytosine dose by the serum creatinine level if azotemia develops.

Use flucytosine with extreme caution in patients with preexisting bone marrow depression, hematologic diseases, or receiving other bone marrow suppressant drugs. Flucytosine should also be used cautiously (with enhanced monitoring) in patients with hepatic disease.

Adverse Effects

Most common adverse effects seen with flucytosine are GI disturbances (nausea, vomiting, diarrhea). Other potential adverse effects include a dose dependent bone marrow depression (anemia, leukopenia, thrombocytopenia), cutaneous eruption and rash primarily seen on the scrotum and nasal planum (occurring in dogs), oral ulceration and increased levels of hepatic enzymes. Dogs receiving flucytosine often develop a severe drug reaction within 10–14 days of treatment.

Reports of aberrant behavior and seizures in a cat without concurrent CNS infection have been noted after flucytosine use. There are anecdotal reports of toxic epidermal necrolysis occurring in cats treated with flucytosine.

Reproductive/Nursing Safety

Flucytosine has caused teratogenic effects in rats. It should be used in pregnant animals only when the benefits of therapy outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in milk. Because there are potential serious adverse reactions in nursing offspring, consider using milk replacer.

Overdosage/Acute Toxicity

No specifics regarding flucytosine overdosage were located. It is suggested that a substantial overdose be handled with gut emptying, charcoal and cathartic administration unless contraindicated.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving flucytosine and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** When used with amphotericin B, synergism against *Cryptococcus* and *Candida* has been demonstrated *in vitro*. However, if amphotericin B induces renal dysfunction, toxicity of flucytosine may be enhanced if it accumulates. Should clinically significant renal toxicity develop, flucytosine dosage may need to be adjusted.

Laboratory Considerations

- When determining serum creatinine using the *Ektachem*® analyzer, false elevations in levels may be noted if patients are also taking flucytosine.

Doses**■ DOGS:**

For cryptococcosis:

- 25–50 mg/kg four times daily PO for a minimum of 6 weeks; with amphotericin B (0.5 mg/kg IV 3 times weekly for a minimum of 4–5 weeks until a cumulative dose of 4 mg/kg attained—see amphotericin B monograph for more information) (Noxon 1989)
- Flucytosine 150–175 mg/kg PO divided three to four times daily with amphotericin B 0.15–0.4 mg/kg IV 3 times a week. When a total dose of amphotericin B reaches 4–6 mg/kg start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month with flucytosine at dosage above or with ketoconazole at 10 mg/kg PO once daily or divided twice daily (Greene, O'Neal, and Barsanti 1984)
- 50–75 mg/kg PO q8h; treatment requires 1–12 months. Must be given with a polyene or azole antifungal agent. (Malik, Krockenberger et al. 2006)

For candidiasis/candiduria:

- To treat aggressively: After correcting identifiable predisposing factors, alkalinize urine to pH of >7.5 with oral sodium bicarbonate. Then give flucytosine at 67 mg/kg PO q8h. Reduce dose if patient has renal failure. (Polzin and Osborne 1985)
- For candidiasis: 25–50 mg/kg PO q6h or 50–65 mg/kg PO q8h for 42 days. Must be given with a polyene or azole antifungal agent. (Greene and Watson 1998)

■ CATS:

For cryptococcosis:

- As an alternate to ketoconazole therapy: Flucytosine 200 mg/kg/day PO divided q6h with amphotericin B (0.25 mg/kg in 30 mL D5W given IV over 15 minutes q48h—See amphotericin B monograph for more information). Continue therapy for 3–4 weeks after clinical signs have resolved and no organisms can be recovered. (Legendre 1989)
- 25–50 mg/kg four times daily PO for a minimum of 4–6 weeks; with amphotericin B (0.25 mg/kg IV 3 times weekly for a minimum of 3–4 weeks—see amphotericin B monograph for more information) (Noxon 1989)
- Flucytosine at 30 mg/kg PO q6h or 50 mg/kg PO q8h or 75 mg/kg PO q12h. Cats 3.5 kg or greater should receive 250 mg (total) q6–8h. Must be given with a polyene (amphotericin B) or azole antifungal agent. Treatment requires 1–9 months. (Malik, Krockenberger et al. 2006)

For candidiasis/candiduria:

- For candidiasis: 25–50 mg/kg PO q6h or 50–65 mg/kg PO q8h for 42 days. Must be given with a polyene or azole antifungal agent (Greene and Watson 1998)

■ BIRDS:

For susceptible fungal infections:

- In Psittacines: 250 mg/kg twice daily as a gavage. May be used for extended periods of time for aspergillosis. May cause bone marrow toxicity; periodic hematologic assessment is recommended.
In raptors: 18–30 mg/kg q6h as a gavage
In Psittacines and Mynahs: 100–250 mg/lb in feed for flock treatment of severe aspergillosis or Candida (especially respiratory Candida). Apply to favorite food mix or mixed with mash. (Clubb 1986)
- Ratites: 80–100 mg/kg PO twice daily (Jenson 1998)

Monitoring

- Renal function (at least twice weekly if also receiving amphotericin B)
- CBC with platelets
- Hepatic enzymes at least monthly

Client Information

- Clients should report any clinical signs associated with hematologic toxicity (abnormal bleeding, bruising, etc.).
- Prolonged treatment times, as well as costs of medication and associated monitoring, require substantial client commitment.

Chemistry/Synonyms

A fluorinated pyrimidine antifungal agent, flucytosine occurs as a white to off-white, crystalline powder that is odorless or has a slight odor with pK_a s of 2.9 and 10.71. It is sparingly soluble in water and slightly soluble in alcohol.

Flucytosine may also be known as: 5-FC, 5-fluorocytosine, flucytosinum, Ro-2-9915, *Alcobon*®, and *Ancotil*®.

Storage/Stability

Store flucytosine capsules in tight, light-resistant containers at temperatures less than 40°C, and preferably at room temperature (15–30°C). The commercially available capsules are assigned an expiration date of 5 years from the date of manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Flucytosine Capsules: 250 mg, & 500 mg; *Ancobon*® (ICN); (Rx)

FLUDROCORTISONE ACETATE

(flue-droe-kor-ti-sone) Florinef®

MINERALOCORTICOID**Prescriber Highlights**

- Oral mineralocorticoid used to treat adrenal insufficiency in small animals; may be useful to treat hyperkalemia as well
- Contraindications: Known hypersensitivity
- Adverse Effects: Dosage related; PU/PD, hypertension, edema, & hypokalemia possible
- May be excreted in significant quantities in milk
- Patients may require supplemental glucocorticoids
- Expense may be an issue, especially in larger dogs

Uses/Indications

Fludrocortisone is used in small animal medicine for the treatment of adrenocortical insufficiency (Addison's disease). It can also be used as adjunctive therapy in hyperkalemia.

Additionally, in humans, fludrocortisone has been used in salt-losing, congenital adrenogenital syndrome and in patients with severe postural hypotension.

Pharmacology/Actions

Fludrocortisone acetate is a potent corticosteroid that possesses both glucocorticoid and mineralocorticoid activity. It is approximately 10–15 times as potent a glucocorticoid agent as hydrocortisone,

but is a much more potent mineralocorticoid (125 times that of hydrocortisone). It is only used clinically for its mineralocorticoid effects.

The site of action of mineralocorticoids is at the renal distal tubule where they increase the absorption of sodium. Mineralocorticoids also enhance potassium and hydrogen ion excretion.

Pharmacokinetics

In humans, fludrocortisone is well absorbed from the GI with peak levels occurring in approximately 1.7 hours; plasma half-life is about 3.5 hours, but biologic activity persists for 18–36 hours.

Contraindications/Precautions/Warnings

Fludrocortisone is contraindicated in patients known to be hypersensitive to it.

Some dogs or cats may require additional supplementation with a glucocorticoid agent on an ongoing basis. All animals with hypoadrenocorticism should receive additional glucocorticoids (2–10 times basal) during periods of stress or acute illness.

Adverse Effects

Adverse effects of fludrocortisone are generally a result of chronic, excessive dosage (see Overdosage below) or if withdrawal is too rapid. Polyuria/polydipsia may be a problem for some dogs. Since fludrocortisone also possesses glucocorticoid activity, it theoretically could cause the adverse effects associated with those compounds. (See the section on the glucocorticoids for more information.)

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Fludrocortisone may be excreted in clinically significant quantities in milk. Puppies or kittens of mothers receiving fludrocortisone should receive milk replacer after colostrum is consumed.

Overdosage/Acute Toxicity

Overdosage may cause hypertension, edema, and hypokalemia. Electrolytes should be aggressively monitored and potassium may need to be supplemented. Patients should have the drug discontinued until clinical signs associated with overdosage have resolved; then restart the drug at a lower dosage.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fludrocortisone and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Patients may develop hypokalemia if fludrocortisone is administered concomitantly with amphotericin B
- **ASPIRIN:** Fludrocortisone may reduce salicylate levels
- **DIURETICS, POTASSIUM-DEPLETING** (e.g., **thiazides, furosemide**): Patients may develop hypokalemia if fludrocortisone is administered concomitantly with diuretics; diuretics can cause a loss of sodium, and may counteract the effects of fludrocortisone
- **INSULIN:** Potentially, fludrocortisone could increase the insulin requirements of diabetic patients

Doses

■ DOGS:

For hypoadrenocorticism:

- a) Maintenance therapy: Initial dosage of 0.015–0.02 mg/kg/day (1.5–2 tablets per 10 kg of body weight), either as a single dose or divided twice a day. Monitor serum sodium and potassium values in 1–2 weeks and adjust dosage by

0.05–0.1 mg per day. Reevaluate unstable dogs and cats every 1–2 months and once stable, once or twice a year. Mild hyponatremia may be corrected by adding salt to the diet. (Reusch 2000)

- b) For maintenance: Initially, 0.01–0.02 mg/kg/day PO and adjusted by 0.05–0.1 mg (total dose) increments based on serial electrolyte determinations. Electrolytes are initially checked weekly until stabilized in normal range. In many dogs, dose requirements increase incrementally over the first 6–24 months. Most dogs will ultimately require 0.02–0.03 mg/kg/day. (Kintzer 2004)
- c) For chronic or subacute therapy: Begin at 0.1 mg (total dose) PO daily for small dogs to 0.5 mg PO daily for large dogs; adjust dose based on serial electrolytes. Also give glucocorticoid supplementation (prednisone or prednisolone 0.2–0.4 mg/kg/day) and IV fluid therapy if required (see reference for more information). (Feldman, Schrader, and Twedt 1988)
- d) When DOCA or DOCP are unavailable, may administer initially at 0.1 mg/5 kg body weight PO once daily; reassessment of serum electrolytes will serve as a guide to further dosage adjustments. (Schaer 2006)

For adjunctive therapy of hyperkalemia:

- a) 0.1–1 mg per day PO; may induce iatrogenic hyperadrenocorticism (Wheeler 1986)

■ CATS:

For maintenance therapy of hypoadrenocorticism:

- a) Once stabilized, 0.1 mg per day PO. Monitor serum electrolytes every 1–2 weeks initially and adjust dosage as necessary. For additional glucocorticoid supplementation, give either oral prednisolone or prednisone at 1.25 mg per day or monthly injections of methylprednisolone acetate 10 mg IM monthly. (Greco and Peterson 1989), (Peterson and Randolph 1989)
- b) Maintenance therapy: 0.05–0.1 mg/cat PO twice daily (Reusch 2000)

■ FERRETS:

For hypoadrenocorticism:

- a) For those animals that still exhibit Addisonian signs even with prednisone therapy: 0.05–0.1 mg/kg PO q24h or divided q12h. (Johnson 2006b)

Monitoring

- Serum electrolytes, BUN, creatinine; initially every 1–2 weeks, then every 3–4 months once stabilized
- Weight, PE for edema

Client Information

- Clients should be familiar with the signs associated with both hypoadrenocorticism (e.g., weakness, depression, anorexia, vomiting, diarrhea, etc.) and fludrocortisone overdosage (e.g., edema) and report these to the veterinarian immediately.

Chemistry/Synonyms

A synthetic glucocorticoid with significant mineralocorticoid activity, fludrocortisone acetate occurs as hygroscopic, fine, white to pale yellow powder or crystals. It is odorless or practically odorless and has a melting point of approximately 225°C. Fludrocortisone is insoluble in water and slightly soluble in alcohol.

Fludrocortisone acetate may also be known as: fluohydrisone acetate, fluohydrocortisone acetate, 9alpha-fluorohydrocortisone acetate, fludrocortisoni acetate, 9alpha-fluorohydrocortisone 21-acetate, *Astonin*®, *Astonin H*®, *Florinef*®, *Florinefe*®, and *Lonikan*®.

Storage/Stability

Fludrocortisone acetate tablets should be stored at room temperature (15–30°C) in well-closed containers; avoid excessive heat. The drug is relatively stable in light and air.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Fludrocortisone Acetate Tablets: 0.1 mg; *Florinef*[®] Acetate (Monarch); generic; (Rx)

FLUMAZENIL

(floo-maz-eh-nill) Romazicon[®]

BENZODIAZEPINE ANTAGONIST**Prescriber Highlights**

- ▶ Benzodiazepine antagonist to reverse either OD's or therapeutic effects
- ▶ Contraindications: Known hypersensitivity, when benzodiazepines are treating life-threatening conditions (e.g., status epilepticus, increased CSF pressure), during tricyclic antidepressant OD treatment
- ▶ Use extreme caution in mixed overdoses
- ▶ Adverse Effects: Potentially injection site reactions, vomiting, cutaneous vasodilatation, vertigo, ataxia, & blurred vision; seizures have been reported in humans
- ▶ Potentially teratogenic at high dosages

Uses/Indications

Flumazenil may be useful for the reversal of benzodiazepine effects after either therapeutic use or overdoses. Flumazenil may be of benefit in the treatment of encephalopathy in patients with severe hepatic failure.

Pharmacology/Actions

Flumazenil is a competitive blocker of benzodiazepines at benzodiazepine receptors in the CNS. It antagonizes the sedative and amnestic qualities of benzodiazepines.

Pharmacokinetics

Flumazenil is administered by rapid IV injection. Therapeutic effect may occur within 1–2 minutes of administration. It is rapidly distributed and metabolized in the liver. In humans, the average half-life is about one hour.

Contraindications/Precautions/Warnings

Flumazenil is contraindicated in patients hypersensitive to it or other benzodiazepines or in patients with where benzodiazepines are being used to treat a potentially life-threatening condition (e.g., status epilepticus, increased CSF pressure). It should not be used in patients with a serious tricyclic antidepressant overdose. Flumazenil should not be used, or used with extreme caution, in patients with mixed overdoses where benzodiazepine reversal may lead to seizures or other complications.

Flumazenil does not alter benzodiazepine pharmacokinetics. Effects of long-acting benzodiazepines may recur after flumazenil's effects subside.

Adverse Effects

In some human patients, flumazenil use has been associated with seizures. These patients usually have a long history of benzodiazepine use or are showing signs of serious tricyclic antidepressant toxicity. Adverse effects reported in humans include injection site reactions, vomiting, cutaneous vasodilatation, vertigo, ataxia and blurred vision. Deaths have been associated with its use in humans having serious underlying diseases.

Overdosage/Acute Toxicity

Large IV overdoses have rarely caused symptoms in otherwise healthy humans. Seizures, if precipitated, have been treated with barbiturates, benzodiazepines and phenytoin, usually with prompt responses.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving flumazenil and may be of significance in veterinary patients:

- **CYCLIC** (tri-, tetra-) **ANTIDEPRESSANTS** (e.g., *clomipramine*, *amitriptyline*, etc.): Increased risk for seizures; use contraindicated
- **NEUROMUSCULAR BLOCKING AGENTS:** Not recommended to use flumazenil until neuromuscular blockade has been fully reversed

Doses■ **DOGS & CATS:**

As an antagonist for benzodiazepines:

- a) Dogs: 0.01 mg/kg IV (Bunch 2003)
- b) Dogs/Cats: 0.01 mg/kg IV; may need to be repeated as half-life is only about an hour. May also be administered intratracheally in an emergency. (Wismer 2004)

For adjunctive therapy to improve neurologic function in dogs with severe hepatic encephalopathy:

- a) 0.02 mg/kg IV (one time) (Bunch 2003)
- b) 0.02 mg/kg IV; if animal responds, safe to use repeatedly (Michel 2003)

Monitoring

- Efficacy
- Monitor for seizures in susceptible patients

Client Information

- Flumazenil should only be used in a controlled environment by clinically experienced professionals.

Chemistry/Synonyms

A benzodiazepine antagonist, flumazenil is a 1,4-imidazobenzodiazepine derivative.

Flumazenil may also be known as: flumazenilum, flumazepil, Ro-15-1788, Ro-15-1788/000, *Anexate*[®], *Fadaflumaz*[®], *Flumage*[®], *Flumanovag*[®], *Flumazen*[®], *Fluxifarm*[®], *Lanexat*[®] and *Romazicon*[®].

Storage/Stability/Compatibility

Flumazenil is physically **compatible** with lactated Ringer's, D5W, or normal saline solutions. Once drawn into a syringe or mixed with the above solutions, discard after 24 hours.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Flumazenil Injection: 0.1 mg/mL in 5 mL and 10 mL vials; *Romazicon*[®] (Hoffman-LaRoche); generic; (Rx)

FLUMETHASONE

(floo-meth-a-sonē) Flucort®

GLUCOCORTICOID

Prescriber Highlights

- ▶ **Injectable & oral glucocorticoid** (oral may not be available commercially in USA)
- ▶ **Long-acting; 15–30X more potent than hydrocortisone; no appreciable mineralocorticoid activity**
- ▶ **Therapy goal is to use as much as is required & as little as possible for as short an amount of time as possible**
- ▶ **Primary adverse effects are “Cushingoid” in nature with sustained use**
- ▶ **Many potential drug & lab interactions**

Uses/Indications

Flumethasone injection (*Flucort*®) is labeled in horses as indicated for: **1)** Musculoskeletal conditions due to inflammation, where permanent structural changes do not exist, such as bursitis, carpalitis, osselets and myositis. Following therapy an appropriate period of rest should be instituted to allow a more normal return to function of the affected part. **2)** In allergic states such as hives, urticaria and insect bites.

Flumethasone injection (*Flucort*®) is labeled in dogs as indicated for: **1)** Musculoskeletal conditions due to inflammation of muscles or joints and accessory structures, where permanent structural changes do not exist, such as arthritis, osteoarthritis, the disc syndrome and myositis. In septic arthritis appropriate antibacterial therapy should be concurrently administered. **2)** In certain acute and chronic dermatoses of varying etiology to help control the pruritus, irritation and inflammation associated with these conditions. The drug has proven useful in otitis externa in conjunction with topical medication for similar reasons. **3)** In allergic states such as hives, urticaria and insect bites. **4)** Shock and shock-like states, by intravenous administration.

Flumethasone injection (*Flucort*®) is labeled in cats as indicated for certain acute and chronic dermatoses of varying etiology to help control the pruritus, irritation and inflammation associated with these conditions.

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. **1)** Replacement of glucocorticoid activity in patients with adrenal insufficiency, **2)** as an antiinflammatory agent, and **3)** as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete.

Pharmacology/Actions

Glucocorticoids have effects on virtually every cell type and system in mammals. An overview of the effects of these agents follows:

Cardiovascular System: Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A relatively clinically insignificant positive inotropic effect can occur after glucocorticoid administration. Increased blood pressure can result from both the drugs' vasoconstrictive properties and increased blood volume that may be produced.

Cells: Glucocorticoids inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes and the cellular response to mediators of inflammation. Glucocorticoids stabilize lysosomal membranes.

CNS/Autonomic Nervous System: Glucocorticoids can lower seizure threshold, alter mood and behavior, diminish the response to pyrogens, stimulate appetite and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.

Endocrine System: When animals are not stressed, glucocorticoids will suppress the release of ACTH from the anterior pituitary, thereby reducing or preventing the release of endogenous corticosteroids. Stress factors (e.g., renal disease, liver disease, diabetes) may sometimes nullify the suppressing aspects of exogenously administered steroids. Release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin, and luteinizing hormone (LH) may all be reduced when glucocorticoids are administered at pharmacological doses. Conversion of thyroxine (T₄) to triiodothyronine (T₃) may be reduced by glucocorticoids; and plasma levels of parathyroid hormone increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (ADH) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin-receptors and the post-receptor effects of insulin.

Hematopoietic System: Glucocorticoids can increase the numbers of circulating platelets, neutrophils and red blood cells, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes and eosinophils are seen as glucocorticoids can sequester these cells into the lungs and spleen and prompt decreased release from the bone marrow. Removal of old red blood cells becomes diminished. Glucocorticoids can cause involution of lymphoid tissue.

GI Tract and Hepatic System: Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased while fat absorption is increased. Hepatic changes can include increased fat and glycogen deposits within hepatocytes, increased serum levels of alanine aminotransferase (ALT), and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum alkaline phosphatase levels. Glucocorticoids can cause minor increases in BSP (bromosulfophthalein) retention time.

Immune System (also see Cells and Hematopoietic System): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; inhibit phagocytosis and chemotaxis; antigen processing; and diminish intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high or very high doses and there are species differences in response.

Metabolic effects: Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (e.g., abdomen) and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glycerol are increased. Protein is mobilized from most areas of the body (not the liver).

Musculoskeletal: Glucocorticoids may cause muscular weakness (also caused if there is a lack of glucocorticoids), atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.

Ophthalmic: Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.

Renal, Fluid, & Electrolytes: Glucocorticoids can increase potassium and calcium excretion, sodium and chloride reabsorption, and extracellular fluid volume. Hypokalemia and/or hypocalcemia rarely occur. Diuresis may develop following glucocorticoid administration.

Skin: Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended and alopecia may occur.

Pharmacokinetics

No information was located for this agent.

Contraindications/Precautions/Warnings

Flumethasone is contraindicated during the last trimester of pregnancy. Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison's), when administered IM in patients with idiopathic thrombocytopenia, and in patients hypersensitive to a particular compound. Use of sustained-release, injectable glucocorticoids is contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically, other than with "burst" therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a "stressor" (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally manifest as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU) may all be seen with short-term "burst" therapy as well as with alternate-day maintenance therapy on days when giving the drug. Adverse effects in dogs can include: dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with antiinflam-

matory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and potentially more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to "Cushingoid" effects, however.

Reproductive/Nursing Safety

Corticosteroid therapy may induce parturition in large animal species during the latter stages of pregnancy. In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Overdosage/Acute Toxicity

Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving flumethasone and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Administered concomitantly with glucocorticoids may cause hypokalemia
- **ANTICHOLINESTERASE AGENTS** (e.g., **pyridostigmine**, **neostigmine**, etc.): In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
- **ASPIRIN:** Glucocorticoids may reduce salicylate blood levels
- **BARBITURATES:** May increase the metabolism of glucocorticoids and decrease flumethasone blood levels
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required
- **CYCLOSPORINE:** Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear
- **DIAZEPAM:** Flumethasone may decrease diazepam levels
- **DIURETICS, POTASSIUM-DEPLETING** (e.g., **spironolactone**, **triamterene**): Administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE:** May reduce flumethasone blood levels
- **INSULIN:** Insulin requirements may increase in patients receiving glucocorticoids
- **KETOCONAZOLE AND OTHER AZOLE ANTIFUNGALS:** May decrease the metabolism of glucocorticoids and increase flumethasone blood levels; ketoconazole may induce adrenal insufficiency when glucocorticoids are withdrawn by inhibiting adrenal corticosteroid synthesis

- **MACROLIDE ANTIBIOTICS** (erythromycin, clarithromycin): May decrease the metabolism of glucocorticoids and increase flumethasone blood levels
- **MITOTANE**: May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDS**: Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration
- **PHENYTOIN**: May increase the metabolism of glucocorticoids and decrease flumethasone blood levels
- **RIFAMPIN**: May increase the metabolism of glucocorticoids and decrease flumethasone blood levels
- **VACCINES**: Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

Laboratory Considerations

- Glucocorticoids may increase **serum cholesterol**
- Glucocorticoids may increase **urine glucose** levels
- Glucocorticoids may decrease **serum potassium**
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T₃ & T₄** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of ¹³¹I by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids
- False-negative results of the **nitroblue tetrazolium** test for systemic bacterial infections may be induced by glucocorticoids
- Glucocorticoids may cause **neutrophilia** within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation
- Glucocorticoids can cause **lymphopenia** which can persist for weeks after drug discontinuation in dogs

Doses

■ DOGS:

For labeled indications (musculoskeletal conditions due to inflammation . . . , certain acute and chronic dermatoses . . . when given orally, and also for allergic states or shock when given intravenously). Treat and adjust dosage on an individual basis:

- a) Orally: 0.0625–0.25 mg daily in divided doses. Dosage is dependent on size of animal, stage and severity of disease. **Note:** Tablets no longer marketed in the USA
Parenterally: 0.0625–0.25 mg IV, IM, SC daily; may repeat;
Intra-articularly: 0.166–1 mg;
Intra-lesionally: 0.125–1 mg (Package insert; *Flucort*®—Fort Dodge)
- b) 0.06–0.25 mg IV, IM, SC, or PO once daily (Kirk 1989)

■ CATS:

For labeled indications (certain acute and chronic dermatoses . . .): Treat and adjust dosage on an individual basis:

- a) Orally: 0.03125–0.125 mg daily in divided doses; **Note:** Tablets no longer marketed in the USA
Parenterally: 0.03125–0.125 mg IV, IM, or SC. If necessary, may repeat. (Package insert; *Flucort*®—Fort Dodge)
- b) 0.03–0.125 mg IV, IM, SC, or PO once daily (Kirk 1989)

■ HORSES: (**Note:** ARCI UCGFS Class 4 Drug)

For labeled indications (musculoskeletal conditions due to inflammation, where permanent changes do not exist; and also for allergic states such as hives, urticaria and insect bites):

- a) 1.25–2.5 mg daily by IV, IM or intra-articular injection. If necessary, the dose may be repeated. (Package insert; *Flucort*®—Fort Dodge)
- b) 1–2.5 mg/450 kg IV or IM (Robinson 1987)

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

Client Information

- Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting with veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects become severe or progress.

Chemistry/Synonyms

Flumethasone occurs as an odorless, white to creamy white, crystalline powder. Its chemical name is 6alpha, 9alpha-difluoro-16alpha methylprednisolone.

Flumethasone may also be known as: flumetasone, glumetasoni pivalas, NSC-107680, *Cerson*®, *Flucort*®, *Locacorten*®, *Locacortene*®, *Locorten*®, *Locortene*®, and *Lorinden*®.

Storage/Stability

Flumethasone injection should be stored at room temperature; avoid freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Flumethasone Injection: 0.5 mg/mL in 100 mL vials; *Flucort*® *Solution* (Fort Dodge); (Rx). Approved for use in dogs, cats, and horses.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

FLUNIXIN MEGLUMINE

(floo-nix-in) Banamine®

NON-STEROIDAL ANTIINFLAMMATORY AGENT

Prescriber Highlights

- ▶ Veterinary-only non-steroidal antiinflammatory agent used in a variety of species
- ▶ Contraindications: History of hypersensitivity
- ▶ Caution in patients with preexisting GI ulcers, renal, hepatic, or hematologic diseases; in horses with colic, flunixin may mask the behavioral & cardiopulmonary signs associated with endotoxemia or intestinal devitalization
- ▶ Use in small animals largely supplanted by approved agents or those with better adverse effect profile in target species
- ▶ If first dose is ineffective for pain control, subsequent doses unlikely to be of benefit
- ▶ Adverse Effects in HORSES & CATTLE: Rare anaphylaxis (especially after rapid IV administration); IM injections (extra-label in food animals) may cause pain/swelling

Uses/Indications

In the United States, flunixin meglumine is approved for use in horses, cattle and swine; however, it is approved for use in dogs in other countries. The approved indications for its use in the horse are for the alleviation of inflammation and pain associated with musculoskeletal disorders and alleviation of visceral pain associated with colic. In cattle it is approved for the control of pyrexia associated with bovine respiratory disease and endotoxemia, and control of inflammation in endotoxemia. In swine, flunixin is approved for use to control pyrexia associated with swine respiratory disease.

Flunixin has been suggested for many other indications in various species, including: Horses: foal diarrheas, shock, colitis, respiratory disease, post-race treatment, and pre- and post ophthalmic and general surgery; Dogs: disk problems, arthritis, heat stroke, diarrheas, shock, ophthalmic inflammatory conditions, pre- and post ophthalmic and general surgery, and treatment of parvovirus infection; Cattle: acute respiratory disease, acute coliform mastitis with endotoxic shock, pain (downer cow), and calf diarrheas; Swine: agalactia/hypogalactia, lameness, and piglet diarrheas. It should be noted that the evidence supporting some of these indications is equivocal and flunixin may not be appropriate for every case.

Pharmacology/Actions

Flunixin is a very potent inhibitor of cyclooxygenase and, like other NSAIDs, it exhibits analgesic, antiinflammatory, and antipyretic activity. Flunixin does not appreciably alter GI motility in horses and may improve hemodynamics in animals with septic shock.

Pharmacokinetics

In the horse, flunixin is rapidly absorbed following oral administration with an average bioavailability of 80% and peak serum levels in 30 minutes. Oral bioavailability is good when the injection is mixed with molasses and given orally. The onset of action is generally within 2 hours; peak response occurs between 12–16 hours and the duration of action lasts up to 30 hours. Flunixin is highly bound to plasma proteins (>99% cattle, 92% dogs, 87% horses). Volume

of distributions ranges from approximately 0.15 L/kg in horses to 0.78 L/kg in cattle. Elimination is primarily via hepatic routes by biliary excretion. Serum half-lives have been determined in horses \approx 1.6–4.2 hours, dogs \approx 3.7 hours; cattle \approx 3.1–8.1 hours. Flunixin is detectable in equine urine for at least 48 hours after a dose.

Contraindications/Precautions/Warnings

The only contraindication the manufacturer lists for flunixin's use in horses is for patients with a history of hypersensitivity reactions to it. It is suggested, however, that flunixin be used cautiously in animals with preexisting GI ulcers, renal, hepatic, or hematologic diseases. When using to treat colic, flunixin may mask the behavioral and cardiopulmonary signs associated with endotoxemia or intestinal devitalization and must be used with caution.

In cattle, the drug is contraindicated in animals that have shown prior hypersensitivity reactions. The IM route is extra-label in cattle and should only be used when the IV route is not feasible for use. Longer withdrawal times would be required after IM use. Flunixin should not be used in an attempt to ambulate cattle to be shipped for slaughter.

Adverse Effects

When used for pain, if the animal does not respond to an initial dose, it is unlikely additional doses will be effective and may result in increased chance for toxicity. In horses following IM injection, reports of localized swelling, induration, stiffness, and sweating have been reported. Do not inject intra-arterially as it may cause CNS stimulation (hysteria), ataxia, hyperventilation, and muscle weakness. Clinical signs are transient and generally do not require any treatment. Flunixin appears to be a relatively safe agent for use in the horse, but the potential exists for GI intolerance, hypoproteinemia, and hematologic abnormalities to occur. Flunixin is not to be used in horses intended for food. Horses have developed oral and gastric ulcers, anorexia, and depression when given high doses for prolonged periods (>2 weeks).

In horses and cattle, rare anaphylactic-like reactions have been reported, primarily after rapid IV administration. IM injections may rarely be associated with clostridial myonecrosis.

Hematochezia and hematuria have been reported in cattle treated for longer than the 3-day recommendation.

In dogs, GI distress is the most likely adverse reaction. Clinical signs may include, vomiting, diarrhea, and ulceration with very high doses or chronic use. There have been anecdotal reports of flunixin causing renal shutdown in dogs when used at higher dosages pre-operatively.

In birds, flunixin has been shown to cause dose-related, significant renal ischemia and nephrotoxicity.

Reproductive/Nursing Safety

Although reports of teratogenicity, effects on breeding performance, or gestation length have not been noted, flunixin should be used cautiously in pregnant animals. Flunixin is not recommended for use in breeding bulls (lack of reproductive safety data).

Flunixin is usually considered to be contraindicated in cats, but some clinicians may use it short-term (see doses). In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Overdosage/Acute Toxicity

No clinical case reports of flunixin overdoses were discovered. It is suggested that acute overdosage be handled by using established protocols of emptying the gut (if oral ingestion and practical or possible) and treating the patient supportively.

Drug Interactions

Drug/drug interactions have not been appreciably studied for flunixin and the label does not mention any drug interactions. However, the following drug interactions have either been reported or are theoretical in humans or animals receiving other NSAIDs and may be of significance in veterinary patients receiving flunixin:

- **ASPIRIN:** When aspirin is used concurrently with NSAIDs, plasma levels of the NSAID could decrease and an increased likelihood of GI adverse effects (blood loss) could occur
- **CYCLOSPORINE:** NSAIDs may increase cyclosporine blood levels and increase the risk for nephrotoxicity
- **DIGOXIN:** NSAIDs may increase serum levels of digoxin; use with caution in patients with severe cardiac failure
- **FUROSEMIDE & OTHER DIURETICS:** NSAIDs may reduce the saluretic and diuretic effects of furosemide
- **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with caution
- **NEPHROTOXIC AGENTS** (e.g., **amphotericin B**, **aminoglycosides**, **cisplatin**, etc.): Potential for increased risk of nephrotoxicity if used with NSAIDs
- **PROBENECID:** May cause a significant increase in serum levels and half-life of some NSAIDs
- **WARFARIN:** Use with NSAIDs may increase the risk for bleeding

Doses

■ DOGS:

Note: Many of these doses are from a time when there were no approved NSAIDs for dogs; consider using approved drugs first.

- a) 0.5–2.2 mg/kg IM or IV one time only (Jenkins 1987)
- b) As an antidiarrheal/antipyretic: 1 mg/kg IV (do not administer more than once in an animal that has received corticosteroids) (Tams 1999)
- c) For ocular indications: 0.25 mg/kg IV once daily for no more than 5 days at a time. May also be used preoperatively by injecting IV 30 minutes before ocular surgery. May dilute 1:9 (flunixin: sterile water) in syringe to administer accurately to very small animals. (Wyman 1986)
- d) For ocular disease: 0.5 mg/kg IV twice daily for 1–2 treatments
For acute gastric dilatation: 1 mg/kg IV once
For GI tract obstruction: 0.5 mg/kg IV once to twice daily for 3 treatments (Morgan 1988)
- e) For surgical pain: 1 mg/kg IV, SC or IM initially once; 1 mg/kg subsequent daily doses
For pyrexia: 0.25 mg/kg IV, SC or IM once, may be repeated in 12–24 hours if needed
For ophtho procedures: 0.25–1 mg/kg IV, IM or SC once; may be repeated in 12–24 hours if needed (Johnson 1996)

■ CATS:

- a) As an antiinflammatory/analgesic:
For surgical pain: 0.25 mg/kg SC once; may be repeated once in 12–24 hours if needed;
For pyrexia: 0.25 mg/kg IV, SC or IM once, may be repeated once in 12–24 hours if needed (Johnson 1996)

■ FERRETS:

- a) 0.5–2 mg/kg PO or IM one time daily (Williams 2000)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: 1.1 mg/kg SC, IM, IV q12–24h (Ivey and Morrissey 2000)
- b) Rabbits: 1.1 mg/kg SC or IM q12h
Rodents: 2.5 mg/kg SC or IM q12h (Huerkamp 1995)
- c) Chinchillas: 1–3 mg/kg SC q12h Guinea pigs: 2.5–5 mg/kg SC q12h Gerbils, Mice, Rats, Hamsters: 2.5 mg/kg SC q12–24h (Adamcak and Otten 2000)

■ CATTLE:

- a) For labeled indications: 1.1–2.2 mg/kg (1–2 mL per 100 lbs. BW) given slow IV either once a day as a single dose or divided into two doses q12h for up to 3 days. Avoid rapid IV administration. (Package Insert; *Banamine*®—Schering).
- b) As an analgesic: 1.1–2.2 mg/kg IV q6–12hours; recommend 72 hour milk withdrawal at this dose rate. (Walz 2006b)
- c) As an analgesic for visceral pain: 0.25–1 mg/kg IV q12–24h. (Anderson 2006a)
- c) For treatment of radial nerve injury: 250–500 mg IV or IM twice daily, may need only one treatment; taper and discontinue usually after 2–3 days (Rebhun 1986) **Note:** See warnings for IM use in the Contraindications section above.
- d) For aseptic lameness in cattle: 1.1 mg/kg; must be administered within 24 hrs after onset of symptoms to be effective (Berg 1986)
- e) 2.2 mg/kg then 1.1 mg/kg q8h IV (Jenkins 1987)

■ HORSES: (**Note:** ARCI UCGFS Class 4 Drug)

- a) Injectable: 1.1 mg/kg IV or IM once daily for up to 5 days. For colic cases, use IV route and may redose when necessary.
Oral Paste: 1.1 mg/kg PO (see markings on syringe—calibrated in 250 lb. weight increments) once daily. One syringe will treat a 1000 lb. horse for 3 days. Do not exceed 5 days of consecutive therapy.
Oral Granules: 1.1 mg/kg PO once daily. One packet will treat 500 lbs of body weight. May apply on feed. Do not exceed 5 consecutive days of therapy. (Package Inserts; *Banamine*®—Schering Animal Health)
- b) For adjunctive treatment of medical colic: 0.25–1.1 mg/kg IV q8–12h; usually 1.1 mg/kg IV q12h. (Blikslager 2006b)
- c) To decrease pain, inflammation, and edema in laminitis: 0.5–1.1 mg/kg IV or PO q8–12 hours. A dose of 0.25 mg/kg can be administered IV q8h to interrupt eicosanoid production associated with endotoxemia. (Moore 2003)
- d) For adjunctive treatment of laminitis: 1.1 mg/kg IM, IV or PO twice daily (Brumbaugh, Lopez et al. 1999)
- e) For adjunctive treatment of uveitis in foals: 0.5–1 mg/kg (route not noted) twice daily (Cutler 2003)

■ SWINE:

- a) To control pyrexia associated with swine respiratory disease: 2.2 mg/kg IM once, only in the neck musculature with a maximum of 10 mL per site. (Label information; *Banamine*®-S—Schering-Plough)

■ BIRDS:

- a) As an antiinflammatory analgesic: 1–10 mg/kg IM once daily. **Note:** Renal disease and death occur occasionally in psittacines after repeated doses of flunixin. Use the lowest possible dose for the shortest duration of time. Recommend supplemental hydration. (Clyde and Paul-Murphy 2000)

Monitoring

- Analgesic/antiinflammatory/antipyretic effects
- GI effects in dogs
- CBC's, occult blood in feces with chronic use in horses

Client Information

- If injecting IM, do not inject into neck muscles.
- The IM route is extra-label in cattle and should only be used when the IV route is not feasible for use. Longer withdrawal times would be required after IM use.
- Flunixin should not be used in an attempt to ambulate cattle to be shipped for slaughter.

Chemistry/Synonyms

Flunixin meglumine, a nonsteroidal antiinflammatory agent is a highly substituted derivative of nicotinic acid, and is unique structurally when compared to other NSAIDs. It occurs as a white to off-white powder that is soluble in water and alcohol. The chemical name for flunixin is 3-pyridine-carboxylic acid.

Flunixin may also be known as 3-pyridine-carboxylic acid, flunixin meglumine, Sch-14714, *Banamine*®, *Flumeglumine*®, and *Finadyne*®, *Flu-Nix*®D, *Flunixamine*®, *Flunixiject*®, *Flunizine*®, *Prevail*®, *Suppressor*®, and *Vedagesic*®.

Storage/Stability/Compatibility

All flunixin products should be stored between 2–30°C (36–86°F). It has been recommended that flunixin meglumine injection not be mixed with other drugs because of unknown compatibilities.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Note: Individual products may be approved and be labeled for different species, lactation status, different routes of administration (IV, IM). Flunixin is also approved only for use in horses not intended for food. Refer to the specific product label for more information

Flunixin Meglumine for Injection: 50 mg/mL in 50 mL, 100 mL and 250 mL vials; At the time of writing, the following products are approved for use in horses and use in beef and dairy cattle (not for use in dry dairy cows or veal calves): *Banamine*® (Schering-Plough), *Flunixin Meglumine Injection* (IVX, Vet Tek, Aspen), *Flumeglumine*® (Phoenix Pharmaceuticals), *Flunixamine*® (Fort Dodge), *Flunixiject*® (Butler), *Prevail*® (VetOne), *Suppressor*® Dairy (RXV), *Flunizine*® (Bimeda), *Vedagesic*® (Vedco); *Flu-Nix*®D (AgriLabs); (Rx). Depending on product, when used as labeled: withdrawal (Cattle): Milk 36 hours; Slaughter 4 days.

Flunixin Meglumine for Injection: 50 mg/mL in 100 mL vials; At the time of writing, the following product is approved for IM use in swine: *Banamine*®-S (Schering-Plough); (Rx) Withdrawal: Slaughter = 12 days.

Flunixin Meglumine for Injection: 50 mg/mL in 100 mL vials; At the time of writing, the following product is approved for use in horses: *Suppressor*® (RXV); (Rx)

Flunixin Meglumine Oral Paste: 1500 mg/syringe in 30 gram syringes in boxes of 6; *Banamine*® Paste (Schering-Plough); (Rx). Approved for use in horses.

Flunixin Meglumine Oral Granules: 250 mg in 10 gram sachets in boxes of 50; 20 g sachets containing 500 mg flunixin in boxes of 25; *Banamine*® Granules (Schering-Plough); (Rx) Approved for use in horses.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

5-Fluorocytosine—see Flucytosine**FLUOROURACIL (5-FU)**

(flure-oh-yoor-a-sill) *Adrucil*®

ANTINEOPLASTIC AGENT**Prescriber Highlights**

- Antineoplastic agent used in dogs for susceptible tumors (see doses) & intralesionally in horses for skin tumors
- **Contraindications:** Do NOT use in any form on cats; Patients hypersensitive to it, in poor nutritional states, depressed bone marrow, serious infections
- Known teratogen
- **Adverse Effects:** Dose-dependent myelosuppression, GI toxicity, & neurotoxicity

Uses/Indications

Chemotherapeutic agent used for canine mammary carcinoma (in combination with doxorubicin and cyclophosphamide—FAC protocol), dermal squamous cell carcinoma and GI tract tumors. It is also used for intralesional injection with epinephrine into certain skin neoplasms (squamous cell carcinoma, melanoma, sarcoid) in horses.

Pharmacology/Actions

Fluorouracil is converted via intracellular mechanisms to active metabolites (fluoruridine monophosphate—FUMP and fluoruridine triphosphate—FUTP). FUMP inhibits the synthesis of deoxythymidine triphosphate thereby interfering with DNA synthesis. FUTP incorporates into RNA and inhibits cell function.

Pharmacokinetics

Fluorouracil is administered systemically via the IV route. It rapidly disappears from the systemic circulation (plasma half live is about 15 minutes in humans) and is primarily distributed into tumor cells, intestinal mucosa, liver, and bone marrow. While some of the drug is converted to active metabolites, (see Pharmacology above), the majority of it is metabolized by the liver. A small amount (about 15% of dose) is excreted unchanged into the urine.

Contraindications/Precautions/Warnings

Cats develop a severe, potentially fatal neurotoxicity when given fluorouracil. It is contraindicated in cats in any form (including topical).

5-FU is contraindicated in patients hypersensitive to it, in poor nutritional states, with depressed or reduced bone marrow function or concurrent serious infections.

Adverse Effects

In dogs, 5-FU causes a dose-dependent myelosuppression, GI toxicity (diarrhea, GI ulceration/sloughing, stomatitis), and neurotoxicity (seizures). Fluorouracil has a very narrow therapeutic index and should be used only by clinicians with experience using cancer chemotherapeutic agents.

Reproductive/Nursing Safety

The drug is a known teratogen and its use should be weighed against any risks to offspring. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is not known whether fluorouracil is excreted in milk. Because fluorouracil inhibits DNA, RNA and protein synthesis, milk replacer should be considered if the dam requires 5-FU.

Overdosage/Acute Toxicity

While overdoses are possible with IV use, careful checking of dosages and preparation should minimize the risks. Oral ingestions of topical products have occurred with dogs. The lowest reported toxic dose at which dogs show adverse signs is 8.6 mg/kg. Seizures and death have been reported at doses as low as 10.3 mg/kg (APCC database). Signs at lower doses include mild GI irritation and vomiting.

There were 332 exposures to **5-Fluorouracil** reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 319 were dogs with 65 showing clinical signs and the remaining 13 cases were cats with 3 showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, seizures, death, euthanasia, and ataxia. Common findings in cats recorded in decreasing frequency included ataxia, anemia, anorexia, blindness, and death.

Should an oral ingestion occur, aggressive GI decontamination with GI protection should be employed and the patient monitored. Seizure control with diazepam is often unrewarding. A barbiturate or general anesthesia is often required. Control of pain is important. Use broad-spectrum antibiotics to prevent secondary bacterial infections. If bone marrow suppression develops, filgrastim (*Neupogen*®) can be used to stimulate bone marrow stem cell proliferation in dogs.

Patients given an accidental parenteral overdose should undergo intensive hematologic monitoring for at least 4 weeks and be supported as required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fluorouracil and may be of significance in veterinary patients:

- **LEUCOVORIN:** May increase the GI toxic effects of 5-FU

Laboratory Considerations

- Fluorouracil may cause increases in alkaline phosphatase, serum transaminase, serum bilirubin, and lactic dehydrogenase

Doses

For more information on using 5-FU as part of chemotherapy protocols, refer to the protocols found in the appendix or other dosages/protocols found in numerous references, including: *Withrow and MacEwen's Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

■ DOGS:

- For canine mammary carcinoma (in combination with doxorubicin and cyclophosphamide—FAC protocol), dermal squamous cell carcinoma and GI tract tumors: 150 mg/m² IV weekly, or 5–10 mg/kg IV weekly (Kitchell and Dhaliwal 2000)

■ CATS:

5-FU is CONTRAINDICATED in cats in any form (including topical)

■ HORSES:

- For intratumoral injection with epinephrine into certain skin neoplasms (squamous cell carcinoma, melanoma, sarcoid): 0.3 mL of 1:1000 epinephrine is added to each mL of 5-FU solution up to a maximum of 3 mL of epinephrine per total volume of 5-FU injected. Epinephrine may result in white hair growth and can cause transient excitation, tachycardia, and shaking if absorbed systemically in sufficient quantities. (Moll 2002)

Monitoring

- CBC's (nadirs usually occur between days 9–14 with recovery by day 30; no dog info located)
- GI and CNS adverse effects
- Efficacy

Client Information

- Clients should understand the serious potential effects of the drug (including death) and be committed for follow-up monitoring

Chemistry/Synonyms

A pyrimidine antagonist antineoplastic agent, fluorouracil (5-FU) occurs as a white, practically odorless, crystalline powder. It is sparingly soluble in water and slightly soluble in alcohol. The commercially available injection has its pH adjusted to 8.6–9.4 and may be colorless or slightly yellow in color.

Fluorouracil may also be known as 5-fluorouracil, fluorouracilo, fluorouracilum, 5-FU, NSC-19893, Ro-2-9757, and WR-69596; many trade names are available.

Storage/Stability/Compatibility

The injection should be stored between 15–30°C; avoid freezing and exposure to light. Slight color changes in the solution can be ignored. If a precipitate forms, the solution can be heated to 60°C and shaken vigorously to redissolve the drug. Cool to body temperature before administering. If unsuccessful in redissolving the drug, it should not be used.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Fluorouracil Injection: 50 mg/mL in 10, 20, 50, & 100 mL vials and 10 mL amps; *Adrucil*® (Gensia Sicor); generic; (Rx)

Also available in topical creams and solutions in concentrations ranging from 0.5% to 5%. These are indicated in humans for treating multiple actinic or solar keratoses, and superficial basal cell carcinomas (5%) when other treatments are impractical.

FLUOXETINE HCL

(floo-ox-e-teen) Prozac®, Reconcile®

SELECTIVE SEROTONIN-REUPTAKE INHIBITOR (SSRI)

Prescriber Highlights

- ▶ A selective-serotonin reuptake inhibitor antidepressant used in dogs & cats for a variety of behavior disorders
- ▶ Contraindications: Patients with known hypersensitivity or receiving monoamine oxidase inhibitors
- ▶ Caution: Patients with diabetes mellitus or seizure disorders; dosages may need to be reduced in patients with severe hepatic impairment
- ▶ Adverse Effects: DOGS: Anorexia, lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting, & aggressive behavior in previously unaggressive dogs is possible; CATS: May exhibit behavior changes (anxiety, irritability, sleep disturbances), anorexia, & changes in elimination patterns
- ▶ Drug Interactions

Uses/Indications

Fluoxetine may be beneficial for the treatment of canine aggression, stereotypic behaviors (and other obsessive-compulsive behaviors), and anxiety. It may be useful in cats for the aforementioned behaviors and, additionally, for inappropriate elimination.

Pharmacology/Actions

Fluoxetine is a highly selective inhibitor of the reuptake of serotonin in the CNS thereby potentiating the pharmacologic activity of serotonin. Fluoxetine apparently has little effect on other neurotransmitters (e.g., dopamine or norepinephrine).

Pharmacokinetics

Fluoxetine is apparently well absorbed after oral administration. In a study done in beagles, approximately 70% of an oral dose reached the systemic circulation. The presence of food altered the rate, but not the extent, of absorption. The oral capsules and oral liquid apparently are bioequivalent.

Fluoxetine and its principal metabolite, norfluoxetine (active), are apparently distributed throughout the body with highest levels found in the lungs and the liver. CNS concentrations are detected within one hour of dosing. In humans, fluoxetine is approximately 95% bound to plasma proteins. Fluoxetine crosses the placenta in rats, but it is unknown if it does so in other species. Fluoxetine enters maternal milk in concentrations about 20–30% of those found in plasma.

Fluoxetine is primarily metabolized in the liver to a variety of metabolites, including norfluoxetine (active). Both fluoxetine and norfluoxetine are eliminated slowly. In humans, the elimination half-life of fluoxetine is about 2–3 days and norfluoxetine, about 7–9 days. In dogs, elimination half-life average for fluoxetine is about 6+ hours and for norfluoxetine, about 2 days; wide interpatient variation does occur, however. Renal impairment does not apparently affect elimination rates substantially, but liver impairment will decrease clearance rates.

Contraindications/Precautions/Warnings

The labeling for the veterinary (canine) approved drug states that fluoxetine should not be used in dogs with epilepsy or a history of seizures, and should not be given with drugs that lower the seizure threshold (e.g., acepromazine, chlorpromazine). Fluoxetine is contraindicated in patients with known hypersensitivity to it, as well as those receiving monoamine oxidase inhibitors (see Drug Interactions below).

Fluoxetine should be used with caution in patients with diabetes mellitus as it may alter blood glucose. Dosages may need to be reduced in patients with severe hepatic impairment.

Adverse Effects

In multi-site field trials in dogs, seizures were reported in some of the dogs treated with fluoxetine. Absolute causality and incidence rate has not been determined. Fluoxetine may cause lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Anorexia is a common side-affect in dogs (usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). Some dogs have persistent anorexia that precludes further treatment. Aggressive behavior in previously unaggressive dogs has been reported. Cats may exhibit behavior changes (anxiety, irritability, sleep disturbances), anorexia, and changes in elimination patterns.

In humans, potential adverse effects are extensive and diverse, but most those most commonly noted include anxiety, nervousness, insomnia, drowsiness, fatigue, dizziness, anorexia, nausea, rash, diarrhea, and sweating; seizures or hepatotoxicity are possible. About 15% of human patients discontinue treatment due to adverse effects.

Reproductive/Nursing Safety

Fluoxetine's safety during pregnancy has not been established. The canine-approved product states that studies to determine the effects of fluoxetine in breeding, pregnant, or lactating dogs or in patients less than 6 months of age have not been conducted. Preliminary studies done in rats demonstrated no overt teratogenic effects. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

The drug is excreted into milk (20–30% of plasma levels), so caution is advised in nursing patients. Clinical implications for nursing offspring are not clear.

Overdosage/Acute Toxicity

The LD₅₀ for rats is 452 mg/kg. Five of six dogs given an oral "toxic" dose developed seizures that immediately stopped after giving IV diazepam. The dog having the lowest plasma level of fluoxetine that developed seizures had a level twice that expected of a human taking 80 mg day (highest recommended dose).

There were 277 exposures to fluoxetine reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 225 were dogs with 18 showing clinical signs, 46 were cats with 5 showing clinical signs. The remaining reported cases were 3 birds, 2 ferrets, and 1 bovine none of which showed clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, agitation, ataxia, hypersalivation and tremors. Common findings in cats recorded in decreasing frequency included hypersalivation, lethargy, agitation and tail chasing.

Treatment of fluoxetine overdoses consists of symptomatic and supportive therapy. Gut emptying techniques should be employed when warranted and otherwise not contraindicated. Diazepam should be used to treat seizures.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fluoxetine and may be of significance in veterinary patients:

- **BUSPIRONE:** Increased risk for serotonin syndrome
- **CYPROHEPTADINE:** May decrease or reverse the effects of SSRIs
- **DIAZEPAM, ALPRAZOLAM:** Fluoxetine may increase diazepam levels
- **DIURETICS:** Increased risk for hyponatremia
- **INSULIN:** May alter insulin requirements
- **ISONIAZID:** Increased risk for serotonin syndrome
- **MAO INHIBITORS** (including **amitraz** and potentially, **selegiline**): High risk for serotonin syndrome; use contraindicated; in humans, a 5 week washout period is required after discontinuing fluoxetine and a 2 week washout period if first discontinuing the MAO inhibitor
- **PENTAZOCINE:** Serotonin syndrome-like adverse effects possible
- **PHENYTOIN:** Increased plasma levels of phenytoin possible
- **PROPRANOLOL, METOPROLOL:** Fluoxetine may increase these beta-blocker's plasma levels; atenolol may be safer to use if fluoxetine required
- **TRICYCLIC ANTIDEPRESSANTS** (e.g., **clomipramine, amitriptyline**): Fluoxetine may increase TCA blood levels and may increase the risk for serotonin syndrome
- **TRAZODONE:** Increased plasma levels of trazodone possible
- **WARFARIN:** Fluoxetine may increase the risk for bleeding

Doses

■ DOGS:

For the adjunctive treatment of behavior disorders (see Indications above):

- a) For the treatment of canine separation anxiety in conjunction with a behavior modification plan: 1–2 mg/kg PO once daily (Label Information; *Reconcile*®—Lilly)
- b) 1 mg/kg PO once to twice daily for 6–8 weeks to start (Overall 2000)
- c) 0.5–1 mg/kg once daily (Line 2000); (Thompson 1999)
- d) 1–1.5 mg/kg daily; Latency to effect is 1–4 weeks (Crowell-Davis 1999)
- e) 1–1.5 mg/kg PO once daily (Seibert 2003)
- f) 1 mg/kg PO once daily (up to 3 mg/kg PO once daily) (Landsberg 2004)

■ CATS:

To help control urine marking or separation anxiety:

- a) 0.5–1 mg/kg PO once daily (Neilson 2006b); (Neilson 2006a)

To control pruritus when other therapies have failed:

- a) 1–5 mg/cat PO once daily; advise obtaining baseline lab work. Assess therapy after 1–4 weeks. Taper off dose over 6–8 weeks. (Messinger 2000)
- b) 0.5–1 mg/kg PO once daily (Overall 2000), (Seibert 2003), (Landsberg 2004)
- c) 0.5–1 mg/kg, daily. Latency to effect is 1–4 weeks (Crowell-Davis 1999)

Monitoring

- Efficacy
- Adverse effects; including appetite (weight)

Client Information

- This medication is most effective when used with a behavior modification program
- Keep this medication away from children and other pets
- Most commonly reported adverse effects with use of this medication include: lethargy/depression, decreased appetite, vomiting, shaking, tremor, restlessness, diarrhea, and excessive vocalization (whining); if these are severe or persist, contact your veterinarian
- Rarely, dogs may develop seizures (convulsion) while receiving this medication; contact veterinarian immediately should this occur

Chemistry/Synonyms

A member of the phenylpropylamine-derivative antidepressant group, fluoxetine differs both structurally and pharmacologically from either the tricyclic or monoamine oxidase inhibitor antidepressants. Fluoxetine HCl occurs as a white to off-white crystalline solid. Approximately 50 mg are soluble in 1 mL of water.

Fluoxetine may also be known as: fluoxetini hydrochloridum, and LY-110140; many trade names are available.

Storage/Stability

Capsules and tablets should be stored in well-closed containers at room temperature. The oral liquid should be stored in tight, light-resistant containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Fluoxetine Chewable Tablets: 8 mg, 16 mg, 32 mg, & 64 mg; *Reconcile*® (Lilly); (Rx). Approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Fluoxetine HCl Tablets: 10 mg & 20 mg (as base); *Prozac*® (Eli Lilly/Dista); generic; (Rx)

Fluoxetine HCl Capsules: 10 mg, 20 mg, 40 mg (as base) and 90 mg (delayed-release); *Prozac*® *Pulvules* & *Prozac*® *Weekly* (Eli Lilly/Dista); *Sarafem*® *Pulvules* (Warner Chilcott); generic; (Rx)

Fluoxetine HCl Oral Solution: 4 mg/mL (as base) in 120 mL & 473 mL; *Prozac*® (Eli Lilly/Dista); generic; (Rx)

FLUTICASONE PROPIONATE

(floo-ti-ca-sone) Flovent®

GLUCOCORTICOID, INHALED/TOPICAL

Prescriber Highlights

- Glucocorticoid used most commonly in veterinary medicine as an inhaled aerosol
- Has shown efficacy in treating feline asthma, dogs with chronic cough, & in horses for recurrent airway obstruction or inflammatory airway disease
- May be useful as a nasally inhaled treatment for allergy-related rhinosinusitis
- Appears to be well tolerated; suppression of HPA axis possible
- Must be used with a species-appropriate delivery device
- Expense may be an issue

Uses/Indications

While there are topical forms of fluticasone, most veterinary interests are in the inhaled versions of the drug. The aerosol for pulmonary inhalation appears to be effective in treating feline asthma, recurrent airway obstruction (RAO, heaves) or inflammatory airway disease (IAD) in horses, and dogs with chronic tracheobronchial disease. While the majority of small animal use has been with fluticasone, there are several other aerosol corticosteroids for inhalation (beclomethasone dipropionate, flunisolide, and triamcinolone acetonide) that theoretically could be used for the same purpose. The nasal inhalation corticosteroid products may be useful for allergy-related chronic rhinosinusitis in cats and dogs.

Pharmacology/Actions

Like other glucocorticoids, fluticasone has potent antiinflammatory activity. Fluticasone has an affinity 18X that of dexamethasone for human glucocorticoid receptors. For a more thorough discussion of glucocorticoid effects, refer to the Glucocorticoids, General Information monograph.

Pharmacokinetics

In humans, when fluticasone aerosol is administered via the lung, about 30% is absorbed into the systemic circulation. In humans, a dose of 880 mcg (4 puffs of the 220 mg aerosol) showed peak plasma concentrations of 0.1 to 1 ng/mL. Volume of distribution averages 4.2 L/kg and it is 91% bound to human plasma proteins. Fluticasone is metabolized via cytochrome P450 3A4 isoenzymes to a metabolite with negligible pharmacologic activity. Terminal elimination half-life is about 8 hours. Most of the drug is excreted in the feces as parent drug and metabolites.

Contraindications/Precautions/Warnings

Fluticasone is contraindicated when patients are hypersensitive to it or during acute bronchospasm (status asthmaticus).

Adverse Effects

In humans, the most likely adverse effects are pharyngitis and upper respiratory infections. While inhaled steroids generally cause significantly fewer adverse effects than injectable or oral therapy, suppression of the HPA axis can occur. When transferring patients from systemic steroid therapy to inhaled steroids, wean slowly off systemic therapy to avoid acute adrenal insufficiency. Prepare to cover patients with additional steroid therapy during periods of acute stress, severe asthma attacks occurring during the withdrawal stage, or after transfer to inhaled steroids. Fluticasone is not useful for acute bronchospasm; cases of fluticasone-induced bronchospasm have been reported in humans.

Reproductive/Nursing Safety

In humans, the FDA categorizes inhaled fluticasone as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). When given subcutaneously to laboratory animals, fluticasone caused a variety of teratogenic effects, including growth retardation, cleft palate, omphalocele and retarded cranial ossification. It should be used during pregnancy only when the benefits clearly outweigh the risks of therapy.

It is not known if the drug enters maternal milk; use with caution in nursing dams.

Overdosage/Acute Toxicity

Acute overdoses of this medication are unlikely, but there have been reported cases of dogs puncturing canisters of albuterol and developing adverse effects. A similar occurrence with fluticasone would

unlikely require treatment. Chronic overdoses could result in significant HPA axis suppression and cushinoid effects.

Drug Interactions

While the manufacturer states that due to the low systemic plasma levels associated with inhalational therapy clinically significant drug interactions are unlikely, use caution when used in conjunction with other drugs (such as **ketoconazole**) that can inhibit CYP 3A4 isoenzymes; theoretically, fluticasone levels could be increased.

Laboratory Considerations

No specific laboratory interactions or considerations were noted.

Doses

■ CATS:

For treatment of feline asthma:

- a) For cats with signs of asthma that occur daily:

Give prednisone at 1–2 mg/kg PO twice daily for 10–14 days. Once a beneficial response to oral prednisone has been documented (usually within 3–5 days) begin inhaled steroids as you wean off oral prednisone.

Use a delivery device (e.g., *AeroKat*®) in combination with a spacer and 110 mcg fluticasone metered dose inhaler. Attach MDI and the facemask to the spacer. Place facemask gently over cat's mouth and nose and actuates the MDI to fill the spacer with medication. The cat breathes in and out for 7–10 times with the mask in place. (Padrid 2006)

■ DOGS:

For adjunctive treatment of chronic tracheobronchial disease:

- a) In dogs with excessive side effects associated with oral steroids therapy: Use a delivery device (e.g., *AeroDawg*®) in combination with either fluticasone 220 mcg or 110 mcg (1 puff) twice daily. Ensure a tightly fitting face mask and counting 7–10 respirations after actuating the MDI into the spacer is important for optimizing therapy. (Johnson 2007)

■ HORSES:

Use a delivery device (e.g., *Aeromask*® or *Equine-haler*®) in combination with a metered dose inhaler:

- a) For the prototypical young racehorse with IAD: Weeks 1 and 2: Fluticasone 2200 mcg (10 puffs) twice daily or beclomethasone HFA 1000 mcg (5 puffs) twice daily with albuterol 450 mcg (5 puffs) prior to steroid inhaler and at approximately 30 minutes before exercise. Weeks 3 and 4: Fluticasone 2200 mcg (10 puffs) once daily or beclomethasone HFA 1000 mcg (5 puffs) twice daily. Recheck in 4 weeks to determine further treatment.

For the typical horse with moderate RAO (heaves): Begin stringent control of environment and a course of systemic prednisone therapy. (**Note:** Reference does not state when oral prednisone should be discontinued.) At week 3 add fluticasone 2200 mcg (10 puffs) twice daily with salmeterol 210 mcg (10 puffs) twice daily. Week 4: fluticasone 2200 mcg (10 puffs) once daily with salmeterol 210 mcg (10 puffs) once daily. If lung function shows a good response at end of 4 weeks: fluticasone 2200 mcg (10 puffs) once every other day with salmeterol 210 mcg (10 puffs) once daily. (Mazan 2002); (Mazan 2003)

Monitoring

■ Efficacy

Client Information

- Before using, shake well and, if possible, bring canister to room temperature. Do not puncture or incinerate can. Must be used with a spacer device appropriate for the species being treated.
- Allow animal to breath with the mask on for 7–10 times before removing
- One puff twice a day will last approximately 2 months

Chemistry/Synonyms

A trifluorinated glucocorticoid, fluticasone propionate occurs as a white to off-white powder that is practically insoluble in water and slightly soluble in ethanol.

Fluticasone may also be known as: CCI-18781, fluticasoni propionas, *Advair Diskus*®, *Cutovate*®, *Flixotide*®, *Flixonase*®, *Flovent*®, and *Flutivate*®.

Storage/Stability/Compatibility

Fluticasone propionate aerosol for inhalation (*Flovent*®) should be stored between 2–30°C (36–86°F); protect from freezing and direct sunlight. Store canister with the mouthpiece down.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Fluticasone Propionate aerosol for inhalation: 44 mcg per actuation, 110 mcg per actuation, 220 mcg per actuation in 7.9 gram and 13 gram canisters. Each 7.9 gram canister contains approximately 60-metered inhalations; 13 gram canister contains approximately 120-metered inhalations when used with the supplied aerosol actuator; *Flovent*® (GlaxoSmithKline); (Rx) **Note:** Dosages referenced above use the 220 mcg/actuation product.

Fluticasone is also available commercially as a Fluticasone Propionate/Salmeterol Powder for Inhalation: 100 mcg fluticasone propionate, 50 mcg salmeterol; 250 mcg fluticasone propionate, 50 mcg salmeterol; & 500 mcg fluticasone propionate, 50 mcg salmeterol) in color-coded blisters; *Advair Diskus*® (GlaxoSmithKline); (Rx)

Nasal solutions, topical creams and ointments containing fluticasone are also available.

FLUVOXAMINE MALEATE

(floo-vox-a-meen) Luvox®

SELECTIVE SEROTONIN-REUPTAKE
INHIBITOR (SSRI)

Prescriber Highlights

- ▶ A selective-serotonin reuptake inhibitor (SSRI) antidepressant similar to fluoxetine; used in dogs & cats for variety of behavior disorders
- ▶ Not commonly used
- ▶ Contraindications: Patients with known hypersensitivity or receiving MAOIs
- ▶ Must treat for 6–8 weeks before evaluating efficacy
- ▶ Caution: Patients with severe cardiac, renal or hepatic disease; dosages may need to be reduced in patients with severe renal or hepatic impairment
- ▶ Adverse effect profile not well established: Potentially, DOGS: Anorexia, lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting; aggressive behavior in previously non-aggressive dogs possible. CATS: May exhibit sedation, decreased appetite/anorexia, vomiting, diarrhea, behavior changes (anxiety, irritability, sleep disturbances), & changes in elimination patterns
- ▶ Drug-drug interactions

Uses/Indications

Fluvoxamine may be considered for use in treating a variety of behavior-related diagnoses in dogs and cats, including aggression and stereotypic behaviors (and other obsessive-compulsive behaviors).

Pharmacology/Actions

Fluvoxamine is a highly selective inhibitor of the reuptake of serotonin in the CNS thereby potentiating the pharmacologic activity of serotonin. Fluvoxamine apparently has little effect on dopamine or norepinephrine, and apparently no effect on other neurotransmitters.

Pharmacokinetics

There is limited data on the pharmacokinetics of fluvoxamine in domestic animals. In dogs, fluvoxamine appears to be completely absorbed; only about 10% of a dose is excreted unchanged in the urine. Half-life appears to be similar to humans (15 hours).

In humans, fluvoxamine is absorbed after oral administration, but bioavailability is only around 50%. Peak plasma concentrations occur between 3–8 hours post-dose. Food does not appear to affect the absorptive characteristics of the drug. Fluvoxamine is widely distributed in the body and about 80% bound to plasma proteins. The drug is extensively metabolized in the liver to non-active metabolites and eliminated in the urine. Plasma half-life is about 15 hours.

Contraindications/Precautions/Warnings

Fluvoxamine is contraindicated in patients hypersensitive to it or any SSRI or if the patient is receiving a monoamine oxidase inhibitor (MAOI) or cisapride. Consider using a lower dosage in patients with hepatic impairment or in geriatric patients.

Adverse Effects

The adverse effect profile of fluvoxamine in dogs or cats has not been well established. In dogs, SSRIs can cause lethargy, GI effects, anxiety, irritability, insomnia/hyperactivity, or panting. Anorexia is a common side effect in dogs (usually transient and may be negated by temporarily increasing the palatability of food and/or hand feeding). Some dogs have persistent anorexia that precludes further treatment. Aggressive behavior in previously non-aggressive dogs has been reported. SSRIs in cats can cause sedation, decreased appetite/anorexia, vomiting, diarrhea, behavior changes (anxiety, irritability, sleep disturbances), and changes in elimination patterns.

In humans, common adverse reactions (>10%) include sexual side effects (abnormal ejaculation, anorgasmia), agitation/nervousness, insomnia, nausea, dry mouth, constipation/diarrhea, dyspepsia, dizziness, headache, and somnolence

Reproductive/Nursing Safety

In humans, the FDA categorizes fluvoxamine as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). In rats, fluvoxamine reportedly increased pup mortality at birth and was associated with decreased birth weights.

Fluvoxamine enters maternal milk, although it appears unlikely to be of significant clinical concern.

Overdosage/Acute Toxicity

Limited data exists for animals. Reportedly, any dosage over 10 mg/kg can cause tremors and lethargy. Other signs associated with overdoses may include vomiting, somnolence/coma, diarrhea, hypotension, heart rate/rhythm disturbances (bradycardia/tachycardia, ECG changes), seizures, etc.

Cyproheptadine may be useful in the adjunctive treatment of serotonin syndrome.

Fatalities have been reported in human overdoses; the highest reported dose where the patient survived was 10,000 mg. Treatment recommendations include standard protocols for drug adsorption/removal from the GI for potentially dangerous overdoses and symptomatic and supportive therapy. Serotonin effects may be negated somewhat by administration (oral or rectal) with cyproheptadine at a dose of 1.1 mg/kg. Seizures or other neurologic signs may be treated with diazepam. The drug has an elimination half-life of approximately 15 hours in dogs.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fluvoxamine and may be of significance in veterinary patients:

- **BUSPIRONE:** Fluvoxamine may paradoxically decrease the clinical efficacy of buspirone
- **CISAPRIDE:** Fluvoxamine may increase plasma levels of cisapride leading to toxicity
- **CYPROHEPTADINE:** May decrease or reverse the effects of SSRIs
- **DIAZEPAM, ALPRAZOLAM, MIDAZOLAM:** Fluvoxamine may increase diazepam levels
- **DILTIAZEM:** Fluvoxamine may increase the effects of diltiazem; bradycardia has been reported in humans taking this drug combination
- **MAO INHIBITORS** (including amitraz and potentially, selegiline): High risk for serotonin syndrome; use contraindicated; in humans, a 5 week washout period is required after discontinuing fluvoxamine and a 2 week washout period if first discontinuing the MAO inhibitor

- **METHADONE:** Fluvoxamine may increase plasma levels of methadone, leading to toxicity
- **PHENYTOIN:** Increased plasma levels of phenytoin possible
- **PROPRANOLOL, METOPROLOL:** Fluvoxamine may increase these beta-blocker's plasma levels; atenolol may be safer to use if fluoxetine required
- **THEOPHYLLINE:** Fluvoxamine may increase plasma levels of theophylline
- **TRICYCLIC ANTIDEPRESSANTS** (e.g., clomipramine, amitriptyline): Fluvoxamine may increase TCA blood levels and may increase the risk for serotonin syndrome
- **WARFARIN:** Fluvoxamine may increase the risk for bleeding

Laboratory Considerations

No fluvoxamine-related laboratory interactions noted.

Doses

■ DOGS:

- a) For treatment of compulsive disorders: 0.5–2 mg/kg PO twice daily (Landsberg 2004)
- b) For treatment of behavioral diagnoses: 1 mg/kg PO q12–24h (once to twice a day); must treat for 3–5 weeks minimum to assess effects; then treat until “well” and either have no signs associated with diagnosis or some low, consistent level (a minimum of another 1–2 months). Continue to treat for another 1–2 months (minimum) so that reliability of assessment is reasonably assured. If weaning off the drug, do so over 3–5 weeks (or longer). Treatment should last for a minimum 4–6 months once initiating therapy. (Overall 2001)

■ CATS:

- a) For treatment of compulsive disorders: 0.25–0.5 mg/kg PO once daily (Landsberg 2004)
- b) For treatment of behavioral diagnoses: 0.25–0.5 mg/kg PO q24h (once a day); must treat for 3–5 weeks minimum to assess effects; then treat until “well” and either have no signs associated with diagnosis or some low, consistent level (a minimum of another 1–2 months). Continue to treat for another 1–2 months (minimum) so that reliability of assessment is reasonably assured. If weaning off the drug, do so over 3–5 weeks (or longer). Treatment should last for a minimum 4–6 months once initiating therapy. (Overall 2001)
- c) For spraying: 0.25 mg/kg PO q12h; avoid use with benzodiazepines (Seksell 2006)

Monitoring

- Efficacy
- Adverse Effects; including appetite (weight)
- Consider doing baseline liver function tests and ECG and re-test as needed

Client Information

- This medication is most effective when used with a behavior modification program
- Keep this medication away from children and other pets
- Because there has not been widespread use of fluvoxamine in dogs or cats, its adverse effect and efficacy profiles have not been yet fully determined; clients should be briefed to report any significant abnormal findings to the veterinarian.
- Clients must understand that this drug is unlikely to have effect immediately or even in the short term, and must commit to using the drug for months so that an adequate trial can occur.

Chemistry/Synonyms

A selective serotonin-reuptake inhibitor (SSRI), fluvoxamine maleate occurs as a white to almost white crystalline powder. It is freely soluble in alcohol and sparingly soluble in water.

Fluvoxamine may also be known as DU-23000, desifluvoxamin, *Dumirox*®, *Dumyrox*®, *Faverin*®, *Favoxil*®, *Felixsan*®, *Fevarin*®, *Floxex*®, *Floxyfral*®, *Fluvohexal*®, *Fluvosol*®, *Fluvoxadura*®, *Fluvoxin*®, *Luvox*®, and *Maveral*®.

Storage/Stability/Compatibility

The commercially available tablets should be stored in tight containers at room temperatures of 15–30° C (59–86° F) and protected from high humidity.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Fluvoxamine Tablets: 25 mg, 50 mg, & 100 mg; generic, (Rx)

FOLIC ACID

(foe-lik ass-id) Folate, Folacin

WATER-SOLUBLE “B” VITAMIN

Prescriber Highlights

- ▶ “B” Vitamin necessary for nucleoprotein synthesis & normal erythropoiesis
- ▶ Injectable or oral dosage forms
- ▶ Folic acid deficiency may be seen in animals (especially cats) with proximal or diffuse small intestinal inflammatory disease
- ▶ May be used when dihydrofolate reductase inhibitor drugs (e.g., trimethoprim, ormetoprim, pyrimethamine) are used for a prolonged period
- ▶ Very safe

Uses/Indications

Folic acid is used to treat folic acid deficiency in dogs, cats, and horses (theoretically in other animal species as well) often due to small intestinal disease. Cats with exocrine pancreatic insufficiency appear to be most at risk for folate and cobalamin deficiencies secondary to malabsorption of folic acid in the diet. Dogs with exocrine pancreatic insufficiency often are noted to have increased folate levels secondary to overgrowths of folate-synthesizing bacteria in the proximal small intestine. Chronic administration of dihydrofolate reductase inhibiting drugs such as pyrimethamine, ormetoprim or trimethoprim can potentially lead to reduced activated folic acid (tetrahydrofolic acid); folic acid supplementation is sometimes prescribed in an attempt to alleviate this situation.

Pharmacology/Actions

Folic acid is required for several metabolic processes. It is reduced via dihydrofolate reductase in the body to tetrahydrofolate (5-methyltetrahydrofolate) which acts as a coenzyme in the synthesis of purine and pyrimidine nucleotides that are necessary for DNA synthesis. Folic acid is also required for maintenance of normal erythropoiesis.

Pharmacokinetics

Therapeutically administered folic acid is primarily absorbed in the proximal small intestine via carrier-mediated diffusion. In humans, synthetic folic acid is nearly completely absorbed after oral administration while folate in foodstuffs is about 50% bioavailable. Folic acid is converted to its active form, tetrahydrofolic acid, principally in the liver and plasma. Folate is distributed widely throughout the body and is stored in the liver. Erythrocyte and CSF levels can be significantly higher than those found in serum. It can undergo enterohepatic recirculation and is excreted primarily in the urine either as metabolites or unchanged drug (when administered in excess of body requirements).

Contraindications/Precautions/Warnings

Folic acid treatment is contraindicated only when known intolerance to the drug is documented. In humans, cobalamin (B-12) levels may be reduced with megaloblastic anemias; folic acid therapy may mask the signs associated with it. Folic acid doses in people above 0.4 mg/day (except during pregnancy and lactation) are not to be used until pernicious anemia has been ruled out.

As dogs may have increased, normal, or decreased folate levels associated with enteropathies, do not administer therapeutic doses until folate and cobalamin levels have been determined.

Adverse Effects

Folic acid is quite non-toxic and should not cause significant adverse effects. Rarely in humans, folic acid tablets or injection have reportedly caused hypersensitivity reactions or gastrointestinal effects. Very high oral doses in humans (15 mg/day) have occasionally caused CNS effects (e.g., difficulty sleeping, excitement, confusion, etc.).

Reproductive/Nursing Safety

Folic acid is safe to use during pregnancy and in humans it is routinely prescribed as part of prenatal vitamin supplementation as folate deficiency can increase the risk for fetal neural tube defects. In humans, the FDA categorizes this drug as category **A** for use during pregnancy (*Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Folic acid is distributed into milk, but is safe. Folic acid requirements may be increased in lactating animals.

Overdosage/Acute Toxicity

Folic acid is relatively non-toxic and no treatment should be required if an inadvertent overdose occurs. Excess drug is metabolized or rapidly excreted unchanged in the urine.

Drug Interactions

The following drug interactions or have been reported in humans and may be of significance in veterinary patients receiving folic acid or may alter patient folic acid requirements:

- **CHLORAMPHENICOL:** May delay response to folic acid
- **METHOTREXATE, TRIMETHOPRIM, PYRIMETHAMINE (drugs that inhibit dihydrofolate reductase):** May interfere with folic acid utilization
- **PHENYTOIN:** May decrease serum folate levels, and phenytoin dosage may need to be increased; increased frequency in seizures can occur
- **SULFASALAZINE, BARBITURATES, NITROFURANTOIN, PRIMIDONE:** May increase risk for folate deficiency

Laboratory Considerations

- Serum samples to be analyzed for cobalamin and/or folate should be protected from bright light and excessive heat
- Hemolysis can cause falsely elevated serum concentrations of folate
- Potentially, decreased cobalamin serum levels (B-12) can occur in patients receiving prolonged folic acid supplementation

Doses**■ DOGS/CATS:**

- For severe folate deficiency: 0.5–2 mg (total dose) once daily for 1 month. (Williams 2000)
- For cats with folate deficiency secondary to exocrine pancreatic insufficiency: 400 mcg (0.4 mg) PO once daily. (Steiner and Williams 2005)
- For cats on long-term use of high dose trimethoprim/sulfa (for treating *Nocardia*): 2 mg (total dose) PO once daily. (Wolf 2006a)
- For dogs with folate and cobalamin deficiency secondary to inflammatory bowel disease: folic acid at 5 mg (total dose) PO once daily for 1–6 months and cyanocobalamin 750 mcg (total dose) parenterally once per month. (Hoskins 2005a)

■ HORSES:

- Prolonged therapy with antifolate medications (e.g., trimethoprim, pyrimethamine): Sometimes recommend folic acid at 20–40 mg (total dose) PO per day. Pregnant mares should routinely receive folic acid supplementation during treatment with antifolates. (Granstrom and Saville 1998)

Monitoring

- Small Animals: folate & cobalamin levels (serum); before and after treatment
- Clinical signs associated with deficiency
- CBC, baseline and ongoing if abnormal

Client Information

- When used to treat folate deficiency associated with small intestinal disease or pancreatic insufficiency, lifelong monitoring and periodic replacement therapy may be required

Chemistry/Synonyms

Folic acid occurs as a yellow, yellow-brownish, or yellowish-orange, odorless crystalline powder. It is very slightly soluble in water and insoluble in alcohol. Commercially available folic acid is obtained synthetically.

Folic acid may also be known as: folate, folacin, vitamin B₉, acidum folicum, pteroylglutamic acid, pteroylmonoglutamic acid, *Folvite*® and vitamin B₁₁.

Storage/Stability

Folic acid tablets should be stored in well-closed containers below 40°C (104°F), preferably between 15–30°C; protect from light and moisture. The injection should be stored protected from light below 40°C (104°F), preferably between 15–30°C. Do not allow to freeze.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

None as sole ingredient products. There are many products available that contain folic acid as one of the ingredients. If using one of these products, be certain it has enough folic acid to treat folate deficiency without overdosing fat soluble vitamins A or D.

HUMAN-LABELED PRODUCTS:

Folic Acid Tablets: 400 mcg (0.4 mg), & 800 mcg (0.8 mg); generic; (depending on label either OTC or Rx)

Folic Acid Tablets: 1 mg; generic; (Rx)

Folic Acid Injection: 5 mg/mL in 10 mL vials; *Folvite*® (Lederle), generic; (Rx)

FOMEPIZOLE

4-METHYLPYRAZOLE (4-MP)

(foe-me-pi-zole) Antizol-Vet®

ANTIDOTE**Prescriber Highlights**

- Synthetic alcohol dehydrogenase inhibitor used to treat dogs for ethylene glycol poisoning
- May be efficacious in cats at high dosages, if given within 3 hours of ingestion
- Adverse Effects: Rapid IV infusion may cause vein irritation & phlebosclerosis; anaphylaxis is potentially possible
- Dilute as directed in the commercially available kit
- Monitor & treat acid/base, fluid, electrolyte imbalances
- May inhibit elimination of ethanol (& vice versa)
- Expense & rapid availability may be issues

Uses/Indications

Fomepizole is used for the treatment of known or suspected ethylene glycol toxicity in dogs (and humans). Fomepizole, at high doses, may be efficacious in treating recent (within 3 hours) ingestion of ethylene glycol in cats.

Pharmacology/Actions

Ethylene glycol itself is only mildly toxic in dogs, but when it is metabolized to glycoaldehyde, glycolate, glyoxalic acid, and oxalic acid, the resultant metabolic acidosis and renal tubular necrosis can be fatal. Fomepizole is a competitive inhibitor of alcohol dehydrogenase, the primary enzyme that converts ethylene glycol into glycoaldehyde and other toxic metabolites. This allows ethylene glycol to be excreted primarily unchanged in the urine decreasing the morbidity and mortality associated with ethylene glycol ingestion.

Pharmacokinetics

Fomepizole is excreted primarily by the kidneys and apparently exhibits a dose-dependent accumulation of the drug over time; therefore, a reduction in subsequent doses can safely occur.

Contraindications/Precautions/Warnings

There are no labeled contraindications to fomepizole's use. Fomepizole has been shown to be effective in treating ethylene glycol in cats, but a high dosage is required.

Adverse Effects

Giving concentrated drug rapidly intravenously may cause vein irritation and phlebosclerosis. Dilute as directed in the commercially available kit.

One dog during clinical trials was reported to develop anaphylaxis.

Use of fomepizole alone without adequate monitoring and adjunctive supportive care (e.g., correction of acid/base, fluid, electrolyte imbalances) may lead to therapeutic failure. If animal presents within 1–2 hours post ingestion, consider inducing vomiting and/or gastric lavage with activated charcoal to prevent further absorption.

Reproductive/Nursing Safety

Fomepizole's safe use during pregnancy, lactation or in breeding animals has not been established. However, because of the morbidity and mortality associated with ethylene glycol toxicity, the benefits of fomepizole should generally outweigh its risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in milk.

Overdosage/Acute Toxicity

Overdosage may cause significant CNS depression. No specific treatment is recommended.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving fomepizole and may be of significance in veterinary patients:

- **ETHANOL:** Fomepizole inhibits alcohol dehydrogenase; ethanol metabolism is reduced significantly and alcohol poisoning (CNS depression, coma, death) can occur. Use together is generally not recommended, but if both drugs are used, monitoring of ethanol blood levels is mandatory.

Doses

■ DOGS:

- a) For treatment of ethylene glycol toxicity: Initially load at 20 mg/kg IV; at 12 hours post initial dose give 15 mg/kg IV; at 24 hours post initial dose give another 15 mg/kg IV and at 36 hours after initial dose give 5 mg/kg; may give additional 5 mg/kg doses as necessary (animal has not recovered or has additional ethylene glycol in blood). (Package Insert; *Antizol-Ver*®)

■ CATS:

- a) For treatment of ethylene glycol toxicity: Initially, 125 mg/kg slow IV; at 12, 24, 36 hours give 31.25 mg/kg IV. In addition, treat supportively with supplemental fluids. Cats must be treated within 3 hours of ingestion. Cats whose treatment began 4 hours post ethylene glycol had 100% mortality with either fomepizole or ETOH therapy. (Connally and Thrall 2002)

Monitoring

- Ethylene glycol blood levels (mostly important to document diagnosis if necessary and to determine if therapy can be discontinued after 36 hours of treatment.)
- Blood gases and serum electrolytes
- Hydration status
- Renal function tests (e.g., Urine output and urinalysis; BUN or serum creatinine)
- Cats: body temperature

Client Information

- Clients should be informed that treatment of serious ethylene glycol toxicity is an “intensive care” admission and that appropriate monitoring and therapy can be quite expensive, particularly when fomepizole is used in large dogs.

- Because time is of the essence in this therapy, clients will need to make an informed decision rapidly. Dogs treated within 8 hours post ingestion have a significantly better prognosis than those treated after 10–12 hours post ingestion. Cats must be treated within 3 hours of ingestion with high dosages.

Chemistry/Synonyms

A synthetic alcohol dehydrogenase inhibitor, fomepizole is commonly called 4-methylpyrazole (4-MP). Its chemical name is 4-methyl-1H-pyrazole. It has a molecular weight of 81; it is soluble in water and very soluble in ethanol.

Fomepizole may also be known as: 4-methylpyrazole, 4-MP, fomezol, fomezolum, and *Antizol*®.

Storage/Stability/Compatibility

Commercially available solutions should be stored at room temperature. The concentrate for injection may solidify at temperatures less than 25°C. Should this occur, resolubilize by running warm water over the vial. Solidification or resolubilization does not affect drug potency or stability. Store reconstituted vial at room temperature and discard after 72 hours. Reconstituted solutions may be further diluted in D5W or normal saline for IV infusion.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Fomepizole 1.5 g Kit for Injection; *Antizol-Ver*® (Jazz); (Rx). Approved for use in dogs. **Note:** At recommended doses 1 kit will treat a 26 kg dog (up to 58 lb.); larger dogs will require additional kits

Preparation: If drug has solidified run warm water over vial; Add entire contents to 30 mL vial of 0.9% NaCl (in kit), mix well. Resultant solution is: 50 mg/mL

HUMAN-LABELED PRODUCTS:

Fomepizole Injection Concentrate (preservative free): 1 g/mL preservative free (must be diluted) in 1.5 mL vials; *Antizol*® (Orphan Medical); (Rx)

FURAZOLIDONE

(fyoor-a-zoe-li-done) Furoxone®

ANTIBACTERIAL/ANTIPROTOZOAL

Prescriber Highlights

- Antibacterial/antiprotozoal nitrofurantoin used primarily in dogs & cats; availability is an issue
- Contraindications: Known hypersensitivity; food animals
- Adverse Effects: GI effects (anorexia, vomiting, cramping & diarrhea) possible
- May innocuously discolor urine to a dark yellow to brown color
- Drug Interactions

Uses/Indications

Furazolidone is usually a drug of second choice in small animals to treat enteric infections caused by the organisms listed below. Because it is no longer commercially available (in the USA), it may be difficult to locate.

Pharmacology/Actions

Furazolidone interferes with susceptible bacterial enzyme systems. Its mechanism against susceptible protozoa is not well determined. Furazolidone has activity against *Giardia*, *Vibrio cholerae*, *Trichomonas*, *Coccidia*, and many strains of *E. coli*, *Enterobacter*, *Campylobacter*, *Salmonella*, and *Shigella*. Not all strains are sensitive, but resistance is usually limited and develops slowly. Furazolidone also inhibits monoamine oxidase.

Pharmacokinetics

Conflicting information on furazolidone's absorption characteristics are published. As colored metabolites are found in the urine, it is clearly absorbed to some extent. Because furazolidone is used to treat enteric infections, absorption becomes important only when discussing adverse reactions and drug interaction issues. Furazolidone reportedly distributes into the CSF. Absorbed furazolidone is rapidly metabolized in the liver and the majority of absorbed drug is eliminated in the urine.

Contraindications/Precautions/Warnings

Furazolidone is contraindicated in patients hypersensitive to it.

The FDA has prohibited the extralabel use of furazolidone in food animals.

Adverse Effects

Adverse effects noted with furazolidone are usually minimal. Anorexia, vomiting, cramping, and diarrhea may occasionally occur. Some human patients are reported to be hypersensitive to the drug. Because furazolidone also inhibits monoamine oxidase it may, potentially, interact with several other drugs and foods (see Drug Interactions below). The clinical significance of these interactions remains unclear, particularly in light of the drug's poor absorptive characteristics.

Reproductive/Nursing Safety

While the safe use of furazolidone during pregnancy has not been established, neither were there any teratogenic issues located for it. However, one reference (Tams 2003b) states that furazolidone should not be used in pregnant queens. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is unknown if furazolidone enters maternal milk.

Overdosage/Acute Toxicity

No information was located; but moderate overdoses are unlikely to cause significant toxicity. Gut emptying may be considered for large overdoses.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving furazolidone and may be of significance in veterinary patients:

■ **ALCOHOL:** With furazolidone may cause a disulfiram-like reaction. Because furazolidone inhibits monoamine oxidase, its use concurrently with the following drugs is not recommended because dangerous hypertension could occur:

- **AMITRAZ**
- **BUSPIRONE**
- **SELEGILINE**
- **SYMPATHOMIMETIC AMINES** (phenylpropanolamine, ephedrine, etc.)
- **TRICYCLIC ANTIDEPRESSANTS**
- **FISH OR POULTRY** (high tyramine content)

Laboratory Considerations

■ Furazolidone may cause a false-positive urine glucose determination when using the cupric sulfate solution test (e.g., *Clinitest*®).

Doses

■ DOGS:

- a) For *amebic colitis*: 2.2 mg/kg PO q8h for 7 days;
For coccidiosis: 8–20 mg/kg PO for one week (Sherding and Johnson 1994)
- b) For treatment of *Giardia*: 4 mg/kg PO twice daily (q12h) for 7 days
For *Cystoisospora* spp.: 8–20 mg/kg PO q12–24h for 5 days (Lappin 2000)
- c) For coccidiosis: 8–20 mg/kg PO once daily for 7 days
For entamebiasis: 2.2 mg/kg PO q8h for 7 days (Greene and Watson 1998)

■ CATS:

- a) For treatment of *Giardia*: 4 mg/kg PO twice daily (q12h) for 7–10 days; if re-treatment is required, elevated dosages or lengthened treatment regimens may provide better results. (Reinemeyer 1992)
- b) For treatment of *Giardia*: 4 mg/kg, PO twice daily (q12h) for 7 days
For *Cystoisospora* spp.: 8–20 mg/kg PO q12–24h for 5 days (Lappin 2000)
- c) For coccidiosis: 8–20 mg/kg PO once daily for 7 days
For giardiasis: 4 mg/kg PO q12h for 5–10 days
For amebiasis: 2.2 mg/kg PO q8h for 7 days (Greene and Watson 1998)
- d) For *amebic colitis*: 2.2 mg/kg PO q8h for 7 days; For coccidiosis: 8–20 mg/kg PO for one week; for *Giardia*: 4 mg/kg PO q12h for 5 days (Sherding and Johnson 1994)

■ HORSES:

- a) 4 mg/kg PO three times daily (Robinson 1992)

Monitoring

■ Efficacy (stool exams for parasitic infections)

Client Information

- Furazolidone may discolor urine to a dark yellow to brown color; this is not significant.
- Have clients report prolonged or serious GI effects.

Chemistry/Synonyms

A synthetic nitrofurant derivative antibacterial/antiprotozoal, furazolidone occurs as a bitter-tasting, yellow, crystalline powder. It is practically insoluble in water.

Furazolidone may also be known as: nifurazolidonum, *Enterolidon*®, *Exofur*®, *Furasian*®, *Furion*®, *Furoxona*®, *Fuxol*®, *Giarcid*®, *Giardil*®, *Giarlam*®, *Neo Furasil*®, *Nifuran*®, *Novafur*®, *Salmocide*®, and *Seforman*®.

Storage/Stability

Store protected from light in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

No systemic products are available; a 4% topical powder/spray is available. The FDA prohibits its use on food producing animals.

HUMAN-LABELED PRODUCTS:

None; the human product *Furoxone*® has apparently been withdrawn from the USA market. Preparations may be available from compounding pharmacies.

FUROSEMIDE

(fur-oh-se-mide) Lasix®

LOOP DIURETIC

Prescriber Highlights

- ▶ A loop diuretic commonly used in many species for treatment of congestive cardiomyopathy, pulmonary edema, udder edema, hypercalcemic nephropathy, uremia, as adjunctive therapy in hyperkalemia &, occasionally, as an antihypertensive agent
- ▶ Used in racehorses to prevent/reduce EIPH
- ▶ Contraindications: Patients with anuria, hypersensitivity, or seriously depleted electrolytes
- ▶ Caution: Patients with pre-existing electrolyte or water balance abnormalities, impaired hepatic function, & diabetes mellitus
- ▶ Adverse Effects: Fluid & electrolyte (esp. hyponatremia) abnormalities, others included: ototoxicity, GI distress, hematologic effects, ototoxicity, weakness, & restlessness
- ▶ Pre-renal azotemia if dehydration occurs
- ▶ Encourage normal food & water intake

Uses/Indications

Furosemide is used for its diuretic activity in all species. It is used in small animals for the treatment of congestive cardiomyopathy, pulmonary edema, hypercalcemic nephropathy, uremia, as adjunctive therapy in hyperkalemia and, occasionally, as an antihypertensive agent. In cattle, it is approved for use for the treatment of post-parturient udder edema. It has been used to help prevent or reduce epistaxis (exercise-induced pulmonary hemorrhage; EIPH) in racehorses.

Pharmacology/Actions

Furosemide reduces the absorption of electrolytes in the ascending section of the loop of Henle, decreases the reabsorption of both sodium and chloride and increases the excretion of potassium in the distal renal tubule, and directly effects electrolyte transport in the proximal tubule. The exact mechanisms of furosemide's effects have not been fully established. It has no effect on carbonic anhydrase nor does it antagonize aldosterone.

Furosemide increases renal excretion of water, sodium, potassium, chloride, calcium, magnesium, hydrogen, ammonium, and bicarbonate. In dogs, excretion of potassium is affected much less so than is sodium; hyponatremia may be more of a concern than hypokalemia. It causes some renal venodilation and transiently increases glomerular filtration rates (GFR). Renal blood flow is increased and decreased peripheral resistance may occur. While furosemide increases renin secretion, due to its effects on the nephron, increases in sodium and water retention do not occur. Furosemide can cause hyperglycemia, but to a lesser extent than the thiazides.

At high doses (10–12 mg/kg), thoracic duct lymph flow is increased in dogs. In horses, guinea pigs and humans, furosemide has some bronchodilative effects. Cats are reportedly more sensitive than other species to the diuretic effects of furosemide.

Pharmacokinetics

The pharmacokinetics of furosemide have been studied in a limited fashion in domestic animals. In dogs, the oral bioavailability is approximately 77% and the elimination half-life approximately 1–1.5 hours.

In humans, furosemide is 60–75% absorbed following oral administration. The diuretic effect takes place within 5 minutes after IV administration and within one hour after oral dosing. Peak effects occur approximately 30 minutes after IV dosing, and 1–2 hours after oral dosing. The drug is approximately 95% bound to plasma proteins in both azotemic and normal patients. The serum half-life is about 2 hours, but prolonged in patients with renal failure, uremia, CHF, and in neonates.

Contraindications/Precautions/Warnings

Furosemide is contraindicated in patients with anuria or who are hypersensitive to the drug. The manufacturer states that the drug should be discontinued in patients with progressive renal disease if increasing azotemia and oliguria occur during therapy.

Furosemide should be used with caution in patients with pre-existing electrolyte or water balance abnormalities, impaired hepatic function (may precipitate hepatic coma), and diabetes mellitus. Patients with conditions that may lead to electrolyte or water balance abnormalities (e.g., vomiting, diarrhea, etc.) should be monitored carefully. Patients hypersensitive to sulfonamides may also be hypersensitive to furosemide (not documented in veterinary species).

Adverse Effects

Furosemide may induce fluid and electrolyte abnormalities. Patients should be monitored for hydration status and electrolyte imbalances (especially potassium, calcium, magnesium and sodium). Prerenal azotemia may result if moderate to severe dehydration occurs. Hyponatremia is probably the greatest concern, but hypocalcemia, hypokalemia, and hypomagnesemia may all occur. Animals that have normal food and water intake are much less likely to develop water and electrolyte imbalances than those who do not.

Other potential adverse effects include ototoxicity, especially in cats with high dose IV therapy. Dogs reportedly require dosages greater than 22 mg/kg IV to cause hearing loss. Other effects include gastrointestinal disturbances, hematologic effects (anemia, leukopenia), weakness, and restlessness.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *B* (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Furosemide appears in milk; clinical significance to nursing offspring is unknown.

Overdosage/Acute Toxicity

The LD₅₀ in dogs after oral administration is >1000 mg/kg; after IV injection >300 mg/kg. Chronic overdosing at 10 mg/kg for six months in dogs led to development of calcification and scarring of the renal parenchyma.

Acute overdosage may cause electrolyte and water balance problems, CNS effects (lethargy to coma and seizures) and cardiovascular collapse.

Treatment consists of emptying the gut after recent oral ingestion, using standard protocols. Avoid giving concomitant cathartics as they may exacerbate the fluid and electrolyte imbalances that can occur. Aggressively monitor and treat electrolyte and water balance abnormalities supportively. Additionally, monitor respiratory, CNS, and cardiovascular status. Treat supportively and symptomatically if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving furosemide and may be of significance in veterinary patients:

- **ACE INHIBITORS** (e.g., **enalapril**, **benazepril**): Increased risks for hypotension, particularly in patients who are volume or sodium depleted secondary to diuretics
- **AMINOGLYCOSIDES** (**gentamicin**, **amikacin**, etc.): Increased risk for ototoxicity
- **AMPHOTERICIN B**: Loop diuretics may increase the risk for nephrotoxicity development; hypokalemia
- **CORTICOSTEROIDS**: Increased risk for GI ulceration; hypokalemia
- **DIGOXIN**: Furosemide-induced hypokalemia may increase the potential for digoxin toxicity
- **INSULIN**: Furosemide may alter insulin requirements
- **MUSCLE RELAXANTS, NON-DEPOLARIZING** (e.g., **atracurium**, **tubocurarine**): Furosemide may prolong neuromuscular blockade
- **PROBENECID**: Furosemide can reduce uricosuric effects
- **SALICYLATES**: Loop diuretics can reduce the excretion of salicylates
- **SUCCINYLCHOLINE**: Furosemide may potentiate
- **THEOPHYLLINE**: Pharmacologic effects of theophylline may be enhanced when used with furosemide

Doses

■ DOGS & CATS:

As a general diuretic:

- a) 2.5–5 mg/kg (lower dose suggested for cats) once or twice daily at 6–8 hour intervals PO, IV or IM (Package Insert; *Salix*®—Intervet)

For cardiogenic or pulmonary edema:

- a) For adjunctive therapy of CHF: 0.5–2 mg/kg PO per day. The goal is to find the lowest dose of furosemide that will prevent development of effusion or edema. This may change over time. (Ware and Keene 2000)

- b) For severe pulmonary edema (parenteral dosing)

Dogs: Up to 7.7 mg/kg IV or IM every 1–2 hours until respiratory rate and/or respiratory character improves;

Cats: Up to 4.4 mg/kg IV or IM every 1–2 hours until respiratory rate and/or respiratory character improves;

For heart failure (oral dosing; often in combination with an ACE inhibitor and digoxin):

Dogs: Dosage ranges from 1.1 mg/kg PO every other day for very mild heart failure to 4.4 mg/kg PO q8h for severe heart failure;

Cats: Dosage ranges from 1.1 mg/kg PO every 2–3 days to 2.2 mg/kg, q8–12h. (May require doses up to 6.6 mg/kg q12h or 15.4 mg/kg PO once a day for cats that are difficult to treat orally).

Animals must drink adequate amounts of water or severe dehydration may result (Kittleson 2000)

- c) The credo for furosemide therapy is: “Use as much as the case requires, and as little as necessary.” Prior to therapy, ob-

tain serum chemistry and full urinalysis (or at least measure urine specific gravity).

For severe pulmonary edema (parenteral dosing):

Dogs: Up to 8 mg/kg IV every hour with adjunctive therapy (usually strict cage rest, O₂ therapy, topical NTG ointment and minimal restraint) until improved.

For chronic maintenance therapy: Usually start at 2 mg/kg PO q12h, but will adjust as necessary. Rarely go above 4 mg/kg PO q8h. If case requires more than this dosage, add hydrochlorothiazide at 2–4 mg/kg PO q12h. However, at this point prognosis is becoming dismal. Encourage oral food and water intake. (Tobias 2001)

- d) Using furosemide as a constant rate infusion (CRI): May dilute 5% injection (50 mg/mL) in D5W to a concentration of 5 mg/mL or 10 mg/mL without precipitation occurring; give as a CRI and titrate dose to between 0.1–1 mg/kg/hour. (Rush 2005a)

For hypercalcemia/hypercalcemic nephropathy:

- a) For adjunctive treatment of moderate to severe hypercalcemia: Volume expansion is necessary prior to use of furosemide; 2–4 mg/kg two to three times daily, IV, SC or PO. (Chew, Schenck et al. 2003)

For acute oliguric renal failure:

- a) Initially 2 mg/kg IV; if no substantial diuresis develops in one hour, the dose may be doubled to 4 mg/kg. If this dose fails to induce diuresis, may increase to 6 mg/kg. If diuresis still does not ensue, very large doses of furosemide, an alternative diuretic (e.g., mannitol), or the combination of furosemide and dopamine may be considered. (Polzin 2005a)

To promote diuresis in hyperkalemic states:

- a) 2 mg/kg IV; attempted if mannitol is ineffective after one hour (Seeler and Thurmon 1985)

As a diuretic for the treatment of ascites:

- a) 1–2 mg/kg PO, SC once to twice daily (Morgan 1988)

■ FERRETS:

For adjunctive therapy for heart failure:

- a) 2–3 mg/kg IM or IV initially for fulminant CHF; 1–2 mg/kg PO q12h for long-term maintenance therapy (Hoeffler 2000)
- b) 1–4 mg/kg PO, SC, IM or IV 2–3 times a day (Williams 2000)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: For CHF: 2–5 mg/kg PO, SC, IM or IV q12h; For pulmonary edema: 1–4 mg/kg IV or IM q4–6h (Ivey and Morrissey 2000)
- b) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 5–10 mg/kg q12h (Adamcak and Otten 2000)

■ CATTLE:

- a) 500 mg once daily or 250 mg twice daily; 2 grams PO once daily. Treatment not to exceed 48 hours post-partum (for udder edema). Package Insert; *Lasix*®—Hoechst)
- b) 2.2–4.4 mg/kg IV q12h (Howard 1986)

■ HORSES:

(Note: Refer to state guidelines for use of furosemide in racing animals)

As a diuretic:

- a) For adjunctive therapy for congestive heart failure: Initially, 1–2 mg/kg IM or IV q6–12h to control edema. Long-term therapy: 0.5–2 mg/kg PO or IM q8–12h (Mogg 1999)
- b) For adjunctive therapy of acute renal failure: 2–4 mg/kg q6h (Jose-Cunilleras and Hinchcliff 1999)

For epistaxis prevention:

- a) 0.3–0.6 mg/kg 60–90 minutes prior to race (Robinson 1987)
- b) 250 mg IV 4 hours prior to racing (Foreman 1999)

■ BIRDS:

As a diuretic:

- a) 0.05 mg/300 gm IM twice daily (**Note:** Lories are very sensitive to this agent and can be easily overdosed) (Clubb 1986)

■ REPTILES:

For most species:

- a) 5 mg/kg IV or IM as needed (Gauvin 1993)

Monitoring

- Serum electrolytes, BUN, creatinine, glucose
- Hydration status
- Blood pressure, if indicated
- Clinical signs of edema, patient weight, if indicated
- Evaluation of ototoxicity, particularly with prolonged therapy or in cats

Client Information

- Clients should contact veterinarian if clinical signs of water or electrolyte imbalance occur, such as excessive thirst, lethargy, lassitude, restlessness, reduced urination, GI distress or fast heart rate.

Chemistry/Synonyms

A loop diuretic related structurally to the sulfonamides, furosemide occurs as an odorless, practically tasteless, white to slightly yellow, fine, crystalline powder. Furosemide has a melting point between 203°–205°C with decomposition, and a pK_a of 3.9. It is practically insoluble in water, sparingly soluble in alcohol, and freely soluble in alkaline hydroxides. The injectable product has its pH adjusted to 8–9.3 with sodium hydroxide.

Furosemide may also be known as: frusemide, furosemidum, and LB-502; many trade names are available.

Storage/Stability/Compatibility

Furosemide tablets should be stored in light-resistant, well-closed containers. The oral solution should be stored at room temperature and protected from light and freezing. Furosemide injection should be stored at room temperature. A precipitate may form if the injection is refrigerated, but will resolubilize when warmed without alteration in potency. The human injection (10 mg/mL) should not be used if it has a yellow color. The veterinary injection (50 mg/mL) normally has a slight yellow color. Furosemide is unstable at an acid pH, but is very stable under alkaline conditions.

Furosemide injection (10 mg/mL) is reportedly physically **compatible** with all commonly used intravenous solutions and the following drugs: amikacin sulfate, cimetidine HCl, kanamycin sulfate, tobramycin sulfate, and verapamil.

It is reportedly physically **incompatible** with the following agents: ascorbic acid solutions, dobutamine HCl, epinephrine, gentamicin sulfate, netilmicin sulfate and tetracyclines. It should generally not be mixed with antihistamines, local anesthetics, alkaloids, hypnotics, or opiates.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Furosemide Tablets: 12.5 mg, 50 mg; *Salix*® (Intervet); *Disal*® Tablets (Boehringer Ingelheim), *Furotabs*® (Butler); generic (Phoenix Pharmaceutical); (Rx). Products may be approved for use in dogs and cats.

Furosemide Oral Solution (Syrup): 10 mg/mL in 60 mL; generic (IVX, First Priority); (Rx) Approved for use in dogs.

Furosemide for Injection: 50 mg/mL (5%) in 50 mL and 100 mL vials; *Disal*® Injection (Boehringer Ingelheim), *Salix*® Injection (Intervet), *Furoject*® (Butler), generic (AgriLabs, IVX, Vet Tek, Phoenix Pharmaceutical), (Rx). Products may be approved for use in dogs, cats and horses.

HUMAN-LABELED PRODUCTS:

Furosemide Tablets: 20 mg, 40 mg, & 80 mg; *Lasix*® (Aventis); generic; (Rx)

Furosemide Oral Solution: 10 mg/mL in 60 mL and 120 mL; 40 mg/5 mL in 500 mL and UD 5 mL and 10 mL; generic; (Rx)

Furosemide Injection: 10 mg/mL in 2 mL, 4 mL and 10 mL single-dose vials and 10 mL multi-dose vial; generic; (Rx)

GABAPENTIN

(gab-ah-pen-tin) Neurontin®

ANTICONVULSANT; NEUROPATHIC
PAIN ANALGESIC

Prescriber Highlights

- May be useful in dogs & cats as adjunctive therapy for refractory or complex partial seizures or the treatment of pain
- Caution in patients with diminished renal function, but dogs partially (30–40%) metabolize the drug (humans do not)
- Avoid use of xylitol-containing oral liquid in dogs
- Sedation most likely adverse effect, but adverse effect profile not well-defined for animals
- Expense may be a significant issue, but may decrease as generics are now available

Uses/Indications

Gabapentin may be useful as adjunctive therapy for refractory or complex partial seizures, or in the treatment of chronic pain in dogs or cats.

Pharmacology/Actions

Gabapentin has analgesic effects and can prevent allodynia (sensation of pain resulting from a normally non-noxious stimulus) or hyperalgesia (exaggerated response to painful stimuli). It also has anticonvulsant activity. The mechanism of action of gabapentin, for either its anticonvulsant or analgesic actions is not understood. While gabapentin is structurally related to GABA, it does not appear to alter GABA binding, reuptake, or degradation, or serve as a GABA agonist *in vivo*.

Pharmacokinetics

In dogs, oral bioavailability is about 80% at a dose of 50 mg/kg. Peak plasma levels occur about 2 hours post dose. Elimination is primarily via renal routes, but gabapentin is partially metabolized to N-methyl-gabapentin. Elimination half-life is approximately 2–4 hours in dogs. No pharmacokinetic data for cats was located.

In humans, gabapentin bioavailability decreases as dosage increases. At doses of 900 mg/day, 60% of the dose is absorbed. Percentage absorbed is reduced as doses are increased to a minimum of 27%

of the dose being absorbed when 4800 mg/day is administered. Presence of food only marginally alters absorption rate and extent of absorption. Gabapentin is only minimally bound to plasma proteins; CSF levels are approximately 20% of those in plasma. The drug is not significantly metabolized and is almost exclusively excreted unchanged into the urine. Elimination half-lives in humans are approximately 5–7 hours.

Contraindications/Precautions/Warnings

Gabapentin is considered contraindicated in patients hypersensitive to it. Because gabapentin is eliminated via renal routes (practically 100% in humans), it should be used with caution in patients with renal insufficiency; if required, dosage adjustment should be considered. In dogs, the drug is also metabolized (30–40%) of a dose, so dosage adjustment may not be required in dogs with mild to moderate renal dysfunction.

In general, avoid the use of the commercially available human oral solution (*Neurontin*®) in dogs as it reportedly contains 300 mg/mL xylitol. As the threshold dose that can cause hypoglycemia in dogs is approximately 100 mg/kg, doses of up to 15 mg/kg in dogs using the solution should be safe, but further data is needed to confirm this. Additionally, xylitol may be hepatotoxic in dogs. Doses of 500 mg/kg of xylitol are currently thought to be the threshold for this toxicity, but there have been anecdotal reports of it occurring at much lower doses. In cats, at the dosages used presently, xylitol toxicity does not appear to be a problem with gabapentin oral solution, but use with caution.

Adverse Effects

Sedation is probably the most likely adverse effect seen in small animals. Starting the dose at the lower end of the range and increasing with time, may alleviate this effect. In humans, the most common adverse effects associated with gabapentin therapy are dizziness, somnolence, and peripheral edema.

Gabapentin was associated with an increased rate of pancreatic adenocarcinoma in male rats. It is unknown if this effect crosses into other species.

Abrupt discontinuation of the drug has lead to withdrawal-precipitated seizures. In humans, it is recommended to wean off the drug when it is used for epilepsy treatment.

Reproductive/Nursing Safety

In humans, the FDA categorizes gabapentin as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). At high dosages (at or above human maximum dosages), gabapentin was associated with a variety of fetotoxic and teratogenic effects (e.g., delayed ossification, hydronephrosis, fetal loss) in rats, mice and rabbits.

Gabapentin enters maternal milk. It has been calculated that a nursing human infant could be exposed to a maximum dosage of 1 mg/kg/day. This is 5–10% of the usual pediatric (>3 yrs old) therapeutic dose. In veterinary patients, this appears unlikely to be of significant clinical concern.

Overdosage/Acute Toxicity

In humans, doses of up to 49 grams have been reported without fatality. Most likely effects include ataxia, lethargy/somnolence, diarrhea, etc.

The commercially available oral solution contains 300 mg/mL; doses of 0.33 mL/kg may cause hypoglycemia or liver toxicity in dogs.

There were 256 exposures to gabapentin reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) dur-

ing 2005–2006. In these cases 211 were dogs with 13 showing clinical signs and the remaining 45 cases were cats with 11 showing clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, ataxia, sedate, vomiting and bulging eyes. Common findings in cats recorded in decreasing frequency included ataxia, lethargy, bradycardia, depression, and mydriasis.

Treatment is basically supportive with general decontamination procedures including emesis, activated charcoal, and cathartics. The drug can be removed with hemodialysis.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving gabapentin and may be of significance in veterinary patients:

- **ANTACIDS:** Oral antacids given concurrently with gabapentin may decrease oral bioavailability by 20%; if antacids are required, separate doses at least 2 hours from gabapentin
- **HYDROCODONE:** Co-administration of gabapentin and hydrocodone may increase the AUC (area under the curve) of gabapentin and increase the efficacy and/or adverse effects of the drug. Gabapentin can reduce the AUC of hydrocodone, potentially reducing the drug's effectiveness.
- **MORPHINE:** May increase gabapentin levels

Laboratory Considerations

- There are reports of gabapentin causing false-positive **urinary protein** readings on *Ames N-Multistix* SG dipstick tests. The use of a sulfosalicylic acid precipitation test to determine presence of urine protein is recommended for patients receiving gabapentin.

Doses

■ DOGS:

For ancillary therapy of refractory seizures:

- a) 10–30 mg/kg PO q8–12h (Podell 2006a)
- b) 25–60 mg/kg/day PO *divided* q6–8h, the author initially uses 10 mg/kg PO q8h. (Dewey 2005b)
- c) 10–30 mg/kg PO q8h. **Note:** expensive and of limited benefit (Berry 2003)

As an analgesic:

- a) For adjunctive treatment of chronic or cancer pain: 3 mg/kg PO once a day (Lascelles 2003)
- b) 1.25–10 mg/kg PO q24h (once daily) (Hardie 2006)

■ CATS:

For ancillary therapy of refractory seizures:

- a) 5 mg/kg PO three times daily (Pearce 2006b)
- b) 5–10 mg/kg PO q8–12h (Podell 2006a)
- c) 10–30 mg/kg PO q8h (**Note:** expensive and of limited benefit) (Berry 2003)

As an analgesic:

- a) 1.25–10 mg/kg PO q24h (once daily) (Hardie 2006)
- b) For adjunctive treatment of chronic or cancer pain: 3 mg/kg PO once a day (Lascelles 2003), (Hardie, Lascelles et al. 2003)
- c) For adjunctive analgesia associated with neuropathic pain: While suggested range in cats is 2.5–5 mg/kg PO q12h, this author starts at 5 mg/kg and increases (up to 10 mg/kg) if no effect seen in two hours. May be a higher requirement in cats for post-seizure or CPR vocalization and thrashing. Wean off slowly or patient may experience worse pain. Reduce in renal insufficiency. Usually the limit of dosing is reached when patient is sedated. (Mathews 2006)

Monitoring

- **Note:** Gabapentin serum levels are not monitored at present.
- Clinical efficacy and adverse effects should be monitored.

Client Information

- Clients should report any significant adverse effects such as ataxia or hypersomnolence

Chemistry/Synonyms

Gabapentin occurs as white to off-white crystalline solid that is freely soluble in water. It has a pK_{a1} of 3.7 and a pK_{a2} of 10.7. It is structurally related to GABA (gamma-aminobutyric acid).

Gabapentin may also be known as: CI-945, GOE-3450, *Aclonium*®, *Equipax*®, *Gantin*®, *Gabarone*®, *Neurontin*®, *Neurostil*® and *Progresse*®.

Storage/Stability/Compatibility

The commercially available capsules and tablets should be stored at room temperature (25°C, 77°F); excursions permitted to 15–30°C (59–86°F). The oral liquid should be stored in the refrigerator at 2–8°C (36–46°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Gabapentin Capsules & Tablets: 100 mg, 300 mg, 400 mg; 600 mg, & 800 mg (film-coated); *Gabarone*® or Gabapentin (Ivax); *Neurontin*® (Pfizer); generic, (Rx)

Gabapentin Solution: 250 mg/5mL (50 mg/mL) in 470 mL; *Neurontin*® (Pfizer); (Rx) **Note:** Contains xylitol. Use with caution in dogs.

GEMCITABINE HCL

(jem-sīe-ah-ben) Gemzar®

ANTINEOPLASTIC

Prescriber Highlights

- ▶ Antineoplastic agent that may potentially be useful for treating several cancers in dogs or cats
- ▶ Very limited clinical use & research performed thus far
- ▶ Myelosuppression most likely adverse effect
- ▶ Very expensive

Uses/Indications

Very limited clinical use and research performed with this drug to date have demonstrated limited clinical efficacy. However, it potentially may be useful as a radiosensitizer for non-resectable tumors, as part of combination protocols, or as a single agent for tumors not amenable to more accepted therapies. Follow research reports for the most up-to-date information.

In humans, gemcitabine has shown some efficacy in treating pancreatic carcinoma, small-cell lung carcinoma, lymphoma, bladder and other soft tissue carcinomas.

Pharmacology/Actions

Gemcitabine exhibits cell phase specificity and acts primarily on the S phase. It also inhibits cell progression through the G1/S-phase boundary.

Gemcitabine is metabolized intracellularly to difluorodeoxycytidine monophosphate (dFdCMP) that is then converted into diphosphate (dFdCDP) and triphosphate (dFdCTP) forms, the metabolites that give the drug its activity. The diphosphate inhibits ribonucleotide reductase. The triphosphate competes with deoxycytidine triphosphate (dTCP; the “normal” nucleotide) for incorporation into DNA strands.

Pharmacokinetics

In dogs, gemcitabine exhibits first order elimination and has a terminal half-life of about 1.5–3.2 hours. Volume of distribution (steady-state) is around 1 L/kg.

In humans, gemcitabine levels achieve steady state in about 15 minutes during a 30 minute infusion. Protein binding is negligible. Volume of distribution is about 50 L/m². Less than 10% of the drug is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

Gemcitabine is contraindicated in patients hypersensitive to it. It should be used with caution in patients with diminished renal or hepatic function.

Adverse Effects

Gemcitabine may cause myelosuppression and can affect red cell, white cell, and platelet cell lines, but neutrophils and platelets appear to be most affected. Neutrophil nadirs usually occur 3–7 days post treatment. GI effects have been reported in animals receiving the drug, but are usually mild. Retinal hemorrhage could occur in animals receiving gemcitabine.

In a pilot study (Kosarek, Kissabeth et al. 2005) in 19 dogs receiving up to 675 mg/m² biweekly demonstrated “minimal and acceptable toxicity.” Another study (Turner, Hahn et al. 2006) where dogs with lymphoma were given gemcitabine as single agent therapy at 400 mg/m² weekly for 3 weeks and then off one week, showed significant decreases in neutrophils and platelets 7 days post treatment. 15 of the 21 dogs in the study required dosage reduction or delay in retreatment. Only 7 of the 21 dogs finished the initial 4 week cycle and a second cycle did not result in any objective therapeutic response.

Reproductive/Nursing Safety

In pregnant humans, gemcitabine is designated by the FDA as a category **D** drug (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is unknown whether gemcitabine is excreted in maternal milk.

Overdosage/Acute Toxicity

There is no known antidote to gemcitabine in an overdose situation. Myelosuppression should be expected. Treatment is supportive.

Drug Interactions

No specific drug interactions were noted, but toxic effects (myelosuppression, GI) could be additive when used with other drugs that also cause those effects.

Laboratory Considerations

No specific laboratory interactions or considerations noted.

Doses**■ DOGS:**

- a) For investigational use in pancreatic adenocarcinoma: Initially 300 mg/m² IV administered over 25–30 minutes weekly for 3–4 weeks, then a one week break. Follow monitoring guidelines below. Consider adding an NSAID such as deracoxib, piroxicam or meloxicam, if renal and liver health is adequate. (de Lorimier 2004b)

■ CATS:

- a) For investigational use when other standards of care, and published options have been attempted and failed: 200 mg/m² in maintenance saline over 20 minutes. Follow monitoring guidelines (below) and do not administer if less than 2,500 neutrophils or less than 80,00 platelets. May give for 3–4 weeks in a row (if tolerated) and then skip one week. (de Lorimier 2004a)

Monitoring

- CBC before each treatment
- Fundic exam weekly while on therapy
- Prior to therapy, baseline renal and hepatic function and periodically thereafter

Client Information

- Owners should understand that veterinary experience with this drug is limited and it must be considered an “investigational” treatment.

Chemistry/Synonyms

A synthetic pyrimidine nucleoside cytarabine analog antineoplastic agent, gemcitabine HCl occurs as white to off-white solid. It is soluble in water and practically insoluble in ethanol or polar organic solvents. Its chemical name is 2,2'-difluorodeoxycytidine.

Gemcitabine may also be known as: dFdC, LY-288022, *Abine*®, *Antoril*®, *Gemicite*®, or *Gemtrol*® and *Gemzar*®.

Storage/Stability/Compatibility

Store unconstituted gemcitabine at controlled room temperature (20–25°C; 68–77°F). After reconstitution with 0.9% sodium chloride injection without preservatives, the resulting solution may be stored at room temperature for up to 24 hours. Reportedly, when frozen at -20°C, the reconstituted solution is stable for 7 days. Do not refrigerate or re-crystallization may occur. Reconstituted solution should not be greater than 40 mg/mL (at least 5 mL of diluent for 200 mg vial; 25 mL diluent for 1 gram vial). Additional diluent may be added to yield concentrations as low as 0.1 mg/mL.

Gemcitabine injection is reportedly physically **incompatible** with the following medications when used via Y-site injection: acyclovir, amphotericin B, cefoperazone, cefotaxime sodium, furosemide, imipenem, methotrexate, methylprednisolone sodium succinate, mitomycin, piperacillin, and prochlorperazine.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Gemcitabine HCl lyophilized Powder for Injection: 200 mg (in 10 mL vial) and 1 g (in 50 mL vial); *Gemzar*® (Lilly); (Rx)

GEMFIBROZIL

(jem-*fi*h-broh-zil) Lipid®

ORAL ANTIHYPERLIPIDEMIC**Prescriber Highlights**

- May be useful as adjunctive therapy (with low fat diet) to treat hypertriglyceridemia in dogs or cats
- Very limited experience & no published clinical studies in dogs or cats; efficacy or safety is not established

Uses/Indications

Gemfibrozil may be useful to reduce serum triglycerides in those dogs or cats with hypertriglyceridemia and when diet modifications alone have been unsuccessful. One reference (Elliott 2005) suggests not adding drug therapy to treat hypertriglyceridemia unless the serum triglyceride concentration exceeds 500 mg/dL with associated clinical signs.

Pharmacology/Actions

Gemfibrozil inhibits lipolysis in adipose tissue and reduces hepatic uptake of plasma free fatty acids causing reduced production of triglycerides. Secondarily, gemfibrozil inhibits the synthesis of very low-density lipoprotein (VLDL) carrier apolipoprotein B, which reduces VLDL production and incorporation of long-chain fatty acids into triglycerides.

Pharmacokinetics

No pharmacokinetic data for dogs or cats was found. In humans, gemfibrozil is rapidly and completely absorbed from the GI tract. The rate and extent of absorption are greatest when administered 30 minutes before a meal. It is highly bound to plasma protein and highest concentrations of the drug are found in the liver and kidneys. In the liver, 4 major metabolites are formed in humans, which are primarily excreted in the urine. Elimination half-life is about 1.5 hours. Reductions in plasma VDL levels are noted within 5 days; peak reductions occur about 4 weeks after starting therapy.

Contraindications/Precautions/Warnings

Contraindications for using gemfibrozil in dogs or cats are not known. In humans, gemfibrozil is contraindicated in patients with severe hepatic or renal dysfunction or with known hypersensitivity to gemfibrozil.

Use with caution in dogs or cats as very limited safety data is available for this medication.

Adverse Effects

Because no clinical studies have been published regarding gemfibrozil use in dogs and cats and clinical use has been quite limited, an accurate adverse effect profile is not known. Anecdotal reports are that the drug has been well tolerated in the few patients that have received the medication, but abdominal pain, vomiting, diarrhea, and abnormal liver function tests have been reported.

In humans, the most common adverse effects reported are GI related (dyspepsia, nausea, vomiting, diarrhea, etc.) and CNS related (headache, paresthesias, somnolence, dizziness, fatigue). Other adverse effects reported include myositis, taste alterations, blurred vision, eczema and decreased libido/impotence. Rarely, hypersensitivity reactions, bone marrow depression, and increases in liver function test values (AST, ALT, Alk Phos, bilirubin) have been reported. Long-term studies in rats have demonstrated an increased

rate of benign and malignant liver tumors when doses were approximately 1.3X of the human dose.

Reproductive/Nursing Safety

Gemfibrozil administered to female rats prior to and during gestation at 0.6–2X the human dose, showed decreased fertility rates and their offspring had an increased incidence of skeletal abnormalities. When given to pregnant rabbits at 1–3X the human dose, litter sizes were decreased and at the highest dose (3X), parietal bone variations were noted. In humans, the FDA categorizes gemfibrozil as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known if gemfibrozil enters milk and safe use during nursing cannot be assured.

Overdosage/Acute Toxicity

Limited information is available. One 7-year-old child ingested up to 9 grams and recovered with supportive treatment. The reported LD50 (oral) in rats is 1414 mg/kg. Consider gut-emptying protocols for recent large oral ingestions and support as required. Monitor for dehydration and electrolyte imbalance if vomiting and/or diarrhea is severe or persists. Monitor liver function tests.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving gemfibrozil and may be of significance in veterinary patients:

- **THIAZIDE DIURETICS, BETA-BLOCKERS, ESTROGENS:** May possibly increase triglyceride concentrations
- **URSODIOL:** May reduce effectiveness of gemfibrozil
- **WARFARIN:** Gemfibrozil may potentiate anticoagulant effects

Laboratory Considerations

No specific concerns associated with gemfibrozil; see Monitoring

Doses

■ DOGS / CATS:

For hypertriglyceridemia that has not been controlled with diet alone:

- a) Dogs: 150 mg–300 mg (total dose) PO q12h; Cats: 7.5–10 mg/kg PO q12h (Jones 2003)
- b) Dogs: 200 mg (total dose) PO once daily;
Cats: 10 mg/kg PO q12h (Elliott 2005)

Monitoring

- Plasma triglycerides; realistic goal for therapy is 400 mg/dL or less
- Baseline and periodic: CBC, liver function tests
- Adverse effects
- If treatment is less effective than hoped, assure that clients have adhered to prescribed diet and dosing schedule before altering dosage

Client Information

- Clients must understand the use of this drug in animals is “investigational”; although approved for use in people, little information is known about it for use in dogs or cats
- Gemfibrozil is used in conjunction with diet modification; lack of adherence to dietary recommendations will likely negate the benefits of using this medication
- Report any significant adverse effects to the veterinarian, including changes in behavior, activity level, gastrointestinal effects

(vomiting, diarrhea, lack of appetite), yellowish eyes or mucous membranes, etc.

Chemistry/Synonyms

Gemfibrozil is a fibric acid derivative that occurs as a waxy, crystalline solid that is practically insoluble in water, but soluble in alcohol.

Gemfibrozil may also be known as: CI-719, gemfibrozilo, or gemfibrozilium; many international trade names are available.

Storage/Stability

Gemfibrozil tablets or capsules should be stored below 30°C in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Gemfibrozil Tablets: 600 mg; *Lopid*® (Parke-Davis), generic; (Rx)

Note: 300 mg capsules are available in Canada

GENTAMICIN SULFATE

(jen-ta-mye-sin) Gentocin®, Garamycin®

AMINOGLYCOSIDE ANTIBIOTIC

Prescriber Highlights

- Parenteral-aminoglycoside antibiotic that has “good” activity against a variety of bacteria, predominantly gram-negative aerobic bacilli, but also many staphylococci strains
- Because of potential adverse effects, usually reserved for serious infections when given systemically
- Adverse effect profile: Nephrotoxicity, ototoxicity, neuromuscular blockade
- Cats may be more sensitive to toxic effects
- Risk factors for nephrotoxicity: Preexisting renal disease, age (both neonatal & geriatric), fever, sepsis, & dehydration
- Usually dosed once daily

Uses/Indications

The inherent toxicity of the aminoglycosides limit their systemic (parenteral) use to the treatment of serious gram-negative infections when there is either a documented lack of susceptibility to other less toxic antibiotics or when the clinical situation dictates immediate treatment of a presumed gram-negative infection before culture and susceptibility results are reported.

Various gentamicin products are approved for parenteral use in dogs, cats, chickens, turkeys, and swine, although the injectable small animal products appear to be no longer marketed. Although routinely used parenterally in horses, gentamicin is only approved for intrauterine infusion in this species. Oral products are approved for gastrointestinal infections in swine and turkeys. For more information, refer to the Dosage section below.

Pharmacology/Actions

Gentamicin has a mechanism of action and spectrum of activity (primarily gram-negative aerobes) similar to the other aminoglycosides. Like the other aminoglycoside antibiotics, it acts on suscep-

tible bacteria presumably by irreversibly binding to the 30S ribosomal subunit thereby inhibiting protein synthesis. It is considered a bactericidal concentration-dependent antibiotic.

Gentamicin's spectrum of activity includes coverage against many aerobic gram-negative and some aerobic gram-positive bacteria, including most species of *E. coli*, *Klebsiella*, *Proteus*, *Pseudomonas*, *Salmonella*, *Enterobacter*, *Serratia*, and *Shigella*, *Mycoplasma*, and *Staphylococcus*. Several strains of *Pseudomonas aeruginosa*, *Proteus*, and *Serratia* that are resistant to gentamicin may still be treated with amikacin.

Antimicrobial activity of the aminoglycosides is enhanced in an alkaline environment.

The aminoglycoside antibiotics are inactive against fungi, viruses and most anaerobic bacteria.

Pharmacokinetics

Gentamicin, like other aminoglycosides, is not appreciably absorbed after oral or intrauterine administration, but is absorbed from topical administration (not skin or urinary bladder) when used in irrigations during surgical procedures. Patients receiving oral aminoglycosides with hemorrhagic or necrotic enteritis may absorb appreciable quantities of the drug. After IM administration to dogs and cats, peak levels occur from ½ to 1 hour later. Subcutaneous injection results in slightly delayed peak levels and with more variability than after IM injection. Bioavailability from extravascular injection (IM or SC) is greater than 90%.

After absorption, aminoglycosides are distributed primarily in the extracellular fluid. They are found in ascitic, pleural, pericardial, peritoneal, synovial and abscess fluids and high levels are found in sputum, bronchial secretions and bile. Aminoglycosides are minimally protein bound (<20%, streptomycin 35%) to plasma proteins. Aminoglycosides do not readily cross the blood-brain barrier or penetrate ocular tissue. CSF levels are unpredictable and range from 0–50% of those found in the serum. Therapeutic levels are found in bone, heart, gallbladder and lung tissues after parenteral dosing. Aminoglycosides tend to accumulate in certain tissues, such as the inner ear and kidneys, which may help explain their toxicity. Volumes of distribution have been reported to be 0.15–0.3 L/kg in adult cats and dogs, and 0.26–0.58 L/kg in horses. Volumes of distribution may be significantly larger in neonates and juvenile animals due to their higher extracellular fluid fractions. Aminoglycosides cross the placenta, but one study showed no detectable levels in foals when gentamicin was administered to mares at term. In other species, fetal concentrations range from 15–50% of those found in maternal serum.

Elimination of aminoglycosides after parenteral administration occurs almost entirely by glomerular filtration. The elimination half-lives for gentamicin have been reported to be 1.82–3.25 hours in horses, 2.2–2.7 hours in calves, 2.4 hours in sheep, 1.8 hours in cows, 1.9 hours in swine, 1 hour in rabbits, and 0.5–1.5 hours in dogs and cats. Patients with decreased renal function can have significantly prolonged half-lives. In humans with normal renal function, elimination rates can be highly variable with the aminoglycoside antibiotics.

Contraindications/Precautions/Warnings

Aminoglycosides are contraindicated in patients who are hypersensitive to them. Because these drugs are often the only effective agents in severe gram-negative infections there are no other absolute contraindications to their use. However, they should be used with extreme caution in patients with preexisting renal disease with concomitant monitoring and dosage interval adjustments made. Other risk factors for the development of toxicity include age (both neonatal and geriatric patients), fever, sepsis and dehydration.

Because aminoglycosides can cause irreversible ototoxicity, they should be used with caution in “working” dogs (e.g., “seeing-eye”, herding, dogs for the hearing impaired, etc.).

Aminoglycosides should be used with caution in patients with neuromuscular disorders (e.g., myasthenia gravis) due to their neuromuscular blocking activity.

Because aminoglycosides are eliminated primarily through renal mechanisms, they should be used cautiously, preferably with serum monitoring and dosage adjustment in neonatal or geriatric animals.

Aminoglycosides are often considered contraindicated in rabbits as they adversely affect the GI flora balance in these animals, but dosages are listed below. Use with caution.

Adverse Effects

The aminoglycosides are infamous for their nephrotoxic and ototoxic effects. The nephrotoxic (tubular necrosis) mechanisms of these drugs are not completely understood, but are probably related to interference with phospholipid metabolism in the lysosomes of proximal renal tubular cells, resulting in leakage of proteolytic enzymes into the cytoplasm. Nephrotoxicity is usually manifested by increases in: BUN, creatinine, non-protein nitrogen in the serum, and decreases in urine specific gravity and creatinine clearance. Proteinuria and cells or casts may also be seen in the urine. Nephrotoxicity is usually reversible once the drug is discontinued. While gentamicin may be more nephrotoxic than the other aminoglycosides, the incidences of nephrotoxicity with all of these agents require equal caution and monitoring.

Ototoxicity (8th cranial nerve toxicity) of the aminoglycosides can manifest by either auditory and/or vestibular clinical signs and may be irreversible. Vestibular clinical signs are more frequent with streptomycin, gentamicin, or tobramycin. Auditory clinical signs are more frequent with amikacin, neomycin, or kanamycin, but other forms can occur with any of the drugs. Cats are apparently very sensitive to the vestibular effects of the aminoglycosides.

The aminoglycosides can also cause neuromuscular blockade, facial edema, pain/inflammation at injection site, peripheral neuropathy, and hypersensitivity reactions. Rarely, GI clinical signs, hematologic and hepatic effects have been reported.

Reproductive/Nursing Safety

Aminoglycosides can cross the placenta and, while rare, may cause 8th cranial nerve toxicity or nephrotoxicity in fetuses. Because the drug should only be used in serious infections, the benefits of therapy may exceed the potential risks. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

While small amounts of gentamicin may be excreted into milk, the risk to nursing offspring appears minimal.

Overdosage/Acute Toxicity

Should an inadvertent overdosage be administered, three treatments have been recommended. **1)** Hemodialysis is very effective in reducing serum levels of the drug, but is not a viable option for most veterinary patients. **2)** Peritoneal dialysis also will reduce serum levels, but is much less effective. **3)** Complexation of drug with ticarcillin (12–20 g/day in humans) is reportedly nearly as effective as hemodialysis.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving gentamicin and may be of significance in veterinary patients:

- **BETA-LACTAM ANTIBIOTICS** (penicillins, cephalosporins): May have synergistic effects against some bacteria; some potential for inactivation of aminoglycosides *in vitro* (do not mix together) and *in vivo* (patients in renal failure)
- **CEPHALOSPORINS**: The concurrent use of aminoglycosides with cephalosporins is somewhat controversial. Potentially, cephalosporins could cause additive nephrotoxicity when used with aminoglycosides, but this interaction has only been well documented with cephaloridine and cephalothin (both no longer marketed).
- **DIURETICS, LOOP** (e.g., furosemide, torsemide) or **OSMOTIC** (e.g., mannitol): Concurrent use with loop or osmotic diuretics may increase the nephrotoxic or ototoxic potential of the aminoglycosides
- **NEPHROTOXIC DRUGS, OTHER** (e.g., cisplatin, amphotericin b, polymyxin B, or vancomycin): Potential for increased risk for nephrotoxicity
- **NEUROMUSCULAR BLOCKING AGENTS & ANESTHETICS, GENERAL**: Concomitant use with general anesthetics or neuromuscular blocking agents could potentiate neuromuscular blockade

Laboratory Considerations

- **Gentamicin serum concentrations** may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior analysis. It is recommended that if assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

Doses

Note: Most infectious disease clinicians now agree that aminoglycosides should be dosed once a day in most patients (mammals). This dosing regimen yields higher peak levels with resultant greater bacterial kill, and as aminoglycosides exhibit a “post-antibiotic effect”, surviving susceptible bacteria generally do not replicate as rapidly even when antibiotic concentrations are below MIC. Periods where levels are low may decrease the “adaptive resistance” (bacteria take up less drug in the presence of continuous exposure) that can occur. Once daily dosing may also decrease the toxicity of aminoglycosides as lower urinary concentrations may mean less-uptake into renal tubular cells. However, patients who are neutropenic (or otherwise immunosuppressed) may benefit from more frequent dosing (q8h).

■ DOGS:

For susceptible infections:

- a) For sepsis: 6 mg/kg IV once daily (Hardie 2000)
- b) 6–8 mg/kg (route not specified) once daily (q24h). Neutropenic or immunocompromised patients may still need to be dosed q8h (dose divided). (Trepanier 1999)
- c) 8 mg/kg once daily or 2–4 mg/kg q8h IV, IM or SC (Aucoin 2002b)
- d) For localized, urinary infections: First dose of 4.4 mg/kg IM, SC and then 2.2 mg/kg IM, SC once daily (q24h) for 7–10 days;
For orthopedic and soft tissue infections: 4.4–6.6 mg/kg IV, IM, SC once daily (q24h) for <7 days.
For bacteremia, sepsis: 6.6 mg/kg IV, IM, SC once daily (q24h) for <7 days.
Monitor renal function by urine sediment examination and serum urea nitrogen levels. (Greene, Hartmann et al. 2006)

- e) For Brucellosis: Gentamicin 5 mg/kg SC once daily (q24h) for 7 days; 2-courses of treatment, treating on weeks one and four; plus Minocycline at 25 mg/kg PO once daily (q24h) for 4 weeks. Eventually, doxycycline can be substituted for minocycline at the same dosage to lower cost. Infected animals may need to be treated for two or more 4-week courses. Sequential antibody tests at 3 to 6 monthly intervals are recommended to monitor treatment. Monitor renal function secondary to gentamicin therapy. (Hartmann and Greene 2005)

■ CATS:

For susceptible infections:

- a) For sepsis: 6 mg/kg IV once daily (Hardie 2000)
- b) 6–8 mg/kg (route not specified) once daily (q24h). Neutropenic or immunocompromised patients may still need to be dosed q8h (dose divided). (Trepanier 1999)
- c) 8 mg/kg once daily or 2–4 mg/kg q8h IV, IM or SC (Aucoin 2002b)
- d) For localized, urinary infections: 2.2 mg/kg IV, IM, SC once daily (q24h) for <7 days;
For bacteremia, sepsis: 4.4 mg/kg IV, IM, SC once daily (q24h) for <7 days.
Monitor renal function by urine sediment examination and serum urea nitrogen levels. (Greene, Hartmann et al. 2006)

■ FERRETS:

For susceptible infections:

- a) 5 mg/kg SC, IM q24h; use with caution or avoid use. (Morrisey and Carpenter 2004)
- b) 4–8 mg/kg IM, SC, IV divided and given 2–3 times daily. Use only when culture and sensitivity dictates. (Williams 2000)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: 5–8 mg/kg daily dose (may divide into q8h–q24h) SC, IM or IV. Increased efficacy and decreased toxicity if given once daily. If given IV, dilute into 4 mL/kg of saline and give over 20 minutes (Ivey and Morrissey 2000)
- b) Chinchillas, Gerbils, Guinea pigs, Hamsters, Mice, Rats: 2–4 mg/kg SC or IM q8–24h (Adamcak and Otten 2000)
- c) Chinchillas: 2–4 mg/kg SC, IM q8–24h (Hayes 2000)

■ CATTLE:

For susceptible infections:

- a) 4.4–6.6 mg/kg/day IM divided three times daily (Upson 1988)
- b) Intramammary: 100–150 mg q12h (Schultz 1986)

■ HORSES:

For susceptible infections:

- a) Foals: 8–10 mg/kg q18–24 hours. Monitor levels to adjust dosage or dosing interval. (Furr 1999)
- b) Adults: 6.6 mg/kg IV or IM once daily (q24h) (Foreman 1999), (Chaffin 2006a)
- c) For intrauterine infusion: 0.5–2 grams. Little science is available for recommending doses, volume infused, frequency, diluents, etc. Most intrauterine treatments are commonly performed every day or every other day for 3–7 days. (Perkins 1999)
- d) Foals: 7 mg/kg IV or IM once daily (q24h) (Giguere 2003a)

■ SWINE:

For susceptible infections:

- a) For colibacillosis in neonates: 5 mg PO or IM once (Label directions; Garacin® Pig Pump and Piglet Injection—Schering)

- b) For weanlings and other swine:
Colibacillosis: 1.1 mg/kg/day in drinking water (concentration of 25 mg/gallon) for 3 days.
Swine dysentery (*Treponema hyodysenteriae*): 2.2 mg/kg/day in drinking water (concentration of 50 mg/gallon) for 3 days (Label directions; *Garacin® Soluble Powder* and *Oral Solution*—Schering)

■ BIRDS:

For susceptible infections:

- For Pheasants and Cranes: 5 mg/kg IM three times daily for 5–10 days. For Quail, African Grey Parrots: 10 mg/kg IM three times daily. Blue and Gold Macaws: 10 mg/kg IM twice daily. Once or twice daily dosing may be effective in less serious infections. (Clubb 1986)
- For gut sterilization/gut infections: 40 mg/kg PO 1–3 times a day for 2–3 days. (Clubb 1986)
- For pneumonia (with carbenicillin or tylosin given IM): 5–10 mg/kg intratracheally once daily (Clubb 1986)
- Ratites: 5 mg/kg IM once daily; **Note:** use only as a last resort as it causes visceral gout (Jenson 1998)

■ REPTILES:

For susceptible infections:

- For bacterial gastritis in snakes: gentamicin 2.5 mg/kg IM every 72 hours with oral neomycin 15 mg/kg plus oral live lactobacillus. (Burke 1986)
- For bacterial shell diseases in turtles: 5–10 mg/kg daily in water turtles, every other day in land turtles and tortoises for 7–10 days. Used commonly with a beta-lactam antibiotic. Recommend beginning therapy with 20 mL/kg fluid injection. Maintain hydration and monitor uric acid levels when possible. (Roskopf 1986)

Monitoring (Parenteral use)

- Efficacy (cultures, clinical signs associated with infection)
- Renal toxicity; baseline urinalysis, serum creatinine/BUN. Casts in the urine are often the initial sign of impending nephrotoxicity. Frequency of monitoring during therapy is controversial. Frequency of monitoring during therapy is controversial, but daily urinalysis and serum creatinine may not be too frequent.
- Gross monitoring of vestibular or auditory toxicity is recommended
- Serum levels, if possible. Draw levels at 1, 2, and 4 hours post dose. Peak should be at least 20 mcg/mL and 4 hour sample should be less than 10 mcg/mL (Papich 2003c).

Client Information

- With appropriate training, owners may give subcutaneous injections at home, but routine monitoring of therapy for efficacy and toxicity must still be done.
- Clients should understand that the potential exists for severe toxicity (nephrotoxicity, ototoxicity) developing from this medication.

Chemistry/Synonyms

An aminoglycoside obtained from cultures of *Micromonaspora purpurea*, gentamicin sulfate occurs as a white to buff powder that is soluble in water and insoluble in alcohol. The commercial product is actually a combination of gentamicin sulfate C₁, C₂, and C₃, but all these compounds apparently have similar antimicrobial activities. Commercially available injections have a pH from 3–5.5.

Gentamicin may also be known as: gentamicin sulphate, gentamicini sulfas, NSC-82261, and Sch-9724; many trade names are available.

Storage/Stability/Compatibility

Gentamicin sulfate for injection and the oral solution should be stored at room temperature (15–30°C); freezing or temperatures above 40°C should be avoided. The soluble powder should be stored from 2–30°C. Do not store or offer medicated-drinking water in rusty containers or the drug may be destroyed.

While the manufacturer does not recommend that gentamicin be mixed with other drugs, it is reportedly physically **compatible** and stable in all commonly used intravenous solutions and with the following drugs: bleomycin sulfate, cefoxitin sodium, cimetidine HCl, clindamycin phosphate, methicillin sodium, metronidazole (with and without sodium bicarbonate), penicillin G sodium, and verapamil HCl.

The following drugs or solutions are reportedly physically **incompatible** or only compatible in specific situations with gentamicin: amphotericin B, ampicillin sodium, carbenicillin disodium, cefamandole naftate, cephalothin sodium, cephalirin sodium, dopamine HCl, furosemide, and heparin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

In vitro inactivation of aminoglycoside antibiotics by beta-lactam antibiotics is well documented. Gentamicin is very susceptible to this effect and it is recommended to avoid mixing these compounds together.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Gentamicin Sulfate Injection: 100 mg/mL in 100 mL and 250 mL vials; *Amtech® Gentamax 100* (IVX), *Gentafuse®* (Butler), *Gentamax® 100* (Phoenix Pharmaceutical), *Gentaved® 100* (Vedco), *Gentozen®* (Schering-Plough), *Legacy®* (AgriLabs); generic; (Rx). Approved for horses.

Gentamicin Sulfate Injection: 100 mg/mL (poultry only) in 100 mL vials; *Garasol® Injection* (Schering-Plough); *Amtech® Gentapoult* (IVX); (OTC) For use in day-old chickens (slaughter withdrawal = 5 weeks) and 1–3 day-old turkeys (slaughter withdrawal=9 weeks) only.

Gentamicin Sulfate Injection: 5 mg/mL in 250 mL vials; *Garacin® Piglet Injection* (Schering-Plough); (OTC). Approved for use in piglets up to 3 days of age. Slaughter (when used as labeled) = 40 days.

Gentamicin Sulfate Oral Solution: 5 mg/mL in 118 mL bottles with pump applicator; *Amtech® Gentamicin Sulfate Pig Pump Oral Solution* (IVX); (Rx); Approved for use in neonatal swine only. Slaughter withdrawal = 14 days.

Gentamicin Soluble Powder: 333.33 mg/g in 360 gram jars. Approved for use in weanling swine. Slaughter withdrawal = 10 days. *Gen-Gard® Soluble Powder* (AgriLabs); (OTC)

Gentamicin Sulfate Soluble Powder: 2 g gentamicin/30 grams of powder in 360-gram jar; *Garacin® Soluble Powder* (Schering-Plough); (OTC). Approved for use in swine. Slaughter (when used as labeled) = 10 days.

Veterinary-approved injections for chickens and turkeys plus a water additive for egg dipping may also be available. Ophthalmic, otic, and topical preparations are available with veterinary labeling.

HUMAN-APPROVED PRODUCTS (partial listing):

Gentamicin Sulfate Injection: 40 mg/mL (as sulfate) in 2 mL and 20 mL vials and 1.5 mL and 2 mL cartridge-needle units; 10 mg/mL (as sulfate) in 2 mL vials & *ADD-Vantage* 60 mg, 80 mg & 100 mg vials; 0.8 mg/mL, 0.9 mg/mL, & 1 mg/mL (as gentamicin base) in 100 mL; 1.2 mg/mL, 1.4 mg/mL & 1.6 mg/mL (as gentamicin base) in 50 mL;

Pediatric Gentamicin Sulfate (Fujisawa); Gentamicin Sulfate in 0.9% Sodium Chloride (Hospira); generic; (Rx)

Topical, otic and ophthalmic labeled products are also available.

GLIMEPIRIDE

(glye-meh-per-ide) Amaryl®

SULFONYLUREA ANTIDIABETIC AGENT

Prescriber Highlights

- ▶ Oral, once-daily, anti-hyperglycemic agent; could be useful in the adjunctive treatment of non-insulin dependent diabetes mellitus (NIDDM) in cats
- ▶ Very limited experience in cats
- ▶ Contraindicated: Patients hypersensitive to it or with diabetic ketoacidosis
- ▶ Hypoglycemia may occur
- ▶ Potentially, significant drug interactions
- ▶ Do not confuse glipizide, glimepiride & glyburide

Uses/Indications

Glimepiride may potentially be a useful adjunct in the treatment of non-insulin dependent diabetes mellitus (NIDDM) in cats. Its duration of action in humans allows it to be dosed once daily, which could be of benefit in cats. It may also have fewer side effects than glipizide in cats.

Pharmacology/Actions

Glimepiride increases pancreatic release of insulin from functioning beta cells and, with continued use, may also increase peripheral tissue sensitivity to insulin. The exact mechanism for these effects is not well understood.

Pharmacokinetics

No pharmacokinetic data for cats was located. In humans, glimepiride is completely absorbed from the GI tract. Peak levels occur in 2–3 hours; food delays the peak somewhat and lowers AUC by about 9%. Volume of distribution is 0.11 L/kg; the drug is greater than 99% bound to plasma proteins. Glimepiride is hepatically metabolized to at least two major metabolites. One of these, M1, has activity at about 1/3 that of the parent compound; clearance is 48 mL/min and elimination half-life about 9 hours. Approximately 60% of the drug (as metabolites) are excreted into the urine and the remainder in the feces. The drug has a 24-hour duration of activity in humans.

Contraindications/Precautions/Warnings

Glimepiride is contraindicated in patients hypersensitive to it or with diabetic ketoacidosis.

Adverse Effects

Hypoglycemia has been reported in about 1% of human patients taking the drug. Dizziness and asthenia have been reported; rarely, liver function impairment, dermatologic reactions, or hematologic reactions have been reported in humans.

Reproductive/Nursing Safety

In humans, the FDA categorizes glimepiride as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or*

there are no animal reproduction studies and no adequate studies in humans). In rabbits and rats, glimepiride did not cause teratogenic effects when given at high dosages. There were some intrauterine deaths when maternal hypoglycemia was induced by the drug.

Some glimepiride is excreted into maternal milk of rats. The manufacturer states to discontinue the drug in nursing, human mothers.

Overdosage/Acute Toxicity

Overdoses may result in hypoglycemia, ranging from mild to severe. Treatment consists of glucose administration and intensive monitoring. Because of the drug's long duration of activity, patients may need to be supported with glucose for a least 48 hours post-ingestion, even after apparent recovery.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glimepiride and may be of significance in veterinary patients:

- **ANTIFUNGALS, AZOLE** (ketoconazole, itraconazole, fluconazole): May increase plasma levels of glimepiride
- **BETA-BLOCKERS**: May potentiate hypoglycemic effect
- **CHLORAMPHENICOL**: May displace glimepiride from plasma proteins
- **CORTICOSTEROIDS**: May reduce efficacy
- **DIURETICS, THIAZIDE**: May reduce hypoglycemic efficacy
- **ISONIAZID**: May reduce hypoglycemic efficacy
- **NIACIN**: May reduce hypoglycemic efficacy
- **PHENOTHIAZINES**: May reduce hypoglycemic efficacy
- **PHENYTOIN**: May reduce hypoglycemic efficacy
- **SULFONAMIDES**: May displace glimepiride from plasma proteins
- **SYMPATHOMIMETIC AGENTS**: May reduce hypoglycemic efficacy
- **WARFARIN**: May displace glimepiride from plasma proteins

Laboratory Considerations

No specific laboratory interactions or considerations were noted.

Doses

■ CATS:

For treatment of NIDDM:

- a) 2 mg (total dose) per cat once daily (Bruyette 2004)
- b) 1–2 mg (total dose per cat) PO once daily (Scherk 2005c)

Monitoring

- Efficacy: Standard methods of monitoring efficacy for diabetes treatment should be followed (e.g., fasting blood glucose, appetite, attitude, body condition, PU/PD resolution and, perhaps, serum fructosamine and/or glycosylated hemoglobin levels)
- Adverse effects

Client Information

- Clients should understand the “investigational” nature of using this drug in cats and report any untoward effects to the veterinarian.

Chemistry/Synonyms

A sulfonylurea antidiabetic agent, glimepiride occurs as a white to yellowish-white, crystalline, odorless to practically odorless powder. It is practically insoluble in water.

Glimepiride may also be known as: HOE-490, Amarel®, Amaryl®, Amarylle®, Euglim®, Glimepil®, Solosa®, and Roname®.

Storage/Stability/Compatibility

Glimepiride tablets should be stored between 15–30°C (59–86°F) in well closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Glimepiride Tablets: 1 mg, 2 mg, & 4 mg; *Amaryl*® (Aventis); generic; (Rx)

GLIPIZIDE

(*glip-i-zide*) Glucotrol®

SULFONYLUREA ANTIDIABETIC AGENT**Prescriber Highlights**

- ▶ Human oral antidiabetic agent (Type II) that may be useful in cats
- ▶ Contraindications: Severe burns/trauma/infection, diabetic coma or other hypoglycemic conditions, major surgery, ketosis, ketoacidosis or other significant acidotic conditions
- ▶ Caution: Untreated adrenal or pituitary insufficiency; thyroid, renal or hepatic function impairment; prolonged vomiting; high fever; malnourishment or debilitated condition
- ▶ Adverse Effects: CATS: GI (*i.e.*, anorexia, vomiting), hypoglycemia, liver toxicity
- ▶ Drug interactions
- ▶ Do not confuse glipizide, glimepiride & glyburide

Uses/Indications

Glipizide may be of benefit in treating cats with type II diabetes if they have a population of functioning beta cells. It has been suggested that there are two situations when glipizide can be recommended, **1**) If an owner refuses to consider using insulin usually due to a fear of needles, and **2**) the cat appears to be relatively well controlled on quite small doses of insulin and the owner would strongly prefer to no longer give insulin (Feldman 2005b).

While glipizide potentially could be useful in treating canine patients with type II or III diabetes, however, by the time dogs present with hyperglycemia, they are absolutely or relatively insulinopenic and glipizide would unlikely be effective.

Pharmacology/Actions

Sulfonylureas lower blood glucose concentrations in both diabetics and non-diabetics. The exact mechanism of action is not known, but these agents are thought to exert the effect primarily by stimulating the beta cells in the pancreas to secrete additional endogenous insulin. Extrapankretic effects include enhanced tissue sensitivity of circulating insulin. Ongoing use of the sulfonylureas appears to enhance peripheral sensitivity to insulin and reduce the production of hepatic basal glucose. The mechanisms causing these effects are yet to be fully explained, however.

Pharmacokinetics

Glipizide is rapidly and practically completely absorbed after oral administration. The absolute bioavailability reported in humans ranges from 80–100%. Food will alter the rate, but not the extent,

of absorption. Glipizide is very highly bound to plasma proteins. It is primarily biotransformed in the liver to inactive metabolites that are then excreted by the kidneys. In humans, half-life is about 2–4 hours. Effects on insulin levels in cats tend to be short-lived. Effects peak in about 15 minutes and return to baseline after about 60 minutes.

Contraindications/Precautions/Warnings

Oral antidiabetic agents are considered contraindicated with the following conditions: severe burns, severe trauma, severe infection, diabetic coma or other hypoglycemic conditions, major surgery, ketosis, ketoacidosis or other significant acidotic conditions. Glipizide should only be used when its potential benefits outweigh its risks during untreated adrenal or pituitary insufficiency; thyroid, renal or hepatic function impairment; prolonged vomiting; high fever; malnourishment or debilitated condition is present.

While glipizide may initially be effective, it may become ineffective in weeks to months after starting therapy; insulin will then be required.

Some patients with type II or type III diabetes may have their disease complicated by the production of excessive amounts of cortisol or growth hormone which may antagonize insulin's effects. These causes should be ruled out before initiating oral antidiabetic therapy.

Adverse Effects

Approximately 15% of cats receiving glipizide develop gastrointestinal adverse effects (*i.e.*, anorexia, vomiting). Vomiting usually will subside in 2–5 days. If it persists or is severe, decrease dose or frequency and, if necessary, discontinue.

Some cats receiving this drug have developed hypoglycemia, but severe hypoglycemia appears to be rare. Should hypoglycemia occur, discontinue glipizide and recheck glucose in one week; may restart at a lower dose or dosing frequency if hyperglycemia is noted.

Effects on the liver have been reported. Serum hepatic enzymes should be checked every 1–2 weeks initially. Discontinue glipizide in cats with elevated enzymes if they develop lethargy, anorexia, vomiting, or if ALT exceeds 500 IU/L; should icterus occur, discontinue glipizide and restart at a lower dose once icterus resolves; discontinue use should icterus reoccur.

Other adverse effects that are possible (noted in humans) include: allergic skin reactions, and bone marrow suppression.

Glipizide does not appear to be effective in cats demonstrating insulin resistance.

Reproductive/Nursing Safety

Safe use during pregnancy has not been established. Glipizide was found to be mildly fetotoxic in rats when given at doses at 5–50 mg/kg; however, no other teratogenic effects were noted. Use in pregnancy only when benefits outweigh potential risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is unknown if glipizide enters milk.

Overdosage/Acute Toxicity

Oral LD₅₀'s are greater than 4 g/kg in all animal species tested. Profound hypoglycemia is the greatest concern after an overdose. Gut emptying protocols should be employed when warranted. Because of its shorter half-life than chlorpropamide, prolonged hypoglycemia is less likely with glipizide, but blood glucose monitoring and treatment with parenteral glucose may be required for several days. Massive overdoses may also require additional monitoring (blood gases, serum electrolytes) and supportive therapy.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glipizide and may be of significance in veterinary patients:

- **ALCOHOL:** A disulfiram-like reaction (anorexia, nausea, vomiting) has been reported in humans who have ingested alcohol within 48–72 hours of receiving glipizide
- **ANTIFUNGALS, AZOLE (ketoconazole, itraconazole, fluconazole):** May increase plasma levels of glipizide
- **BETA-BLOCKERS:** May potentiate hypoglycemic effect
- **CHLORAMPHENICOL:** May displace glipizide from plasma proteins
- **CIMETIDINE:** May potentiate hypoglycemic effect
- **CORTICOSTEROIDS:** May reduce efficacy
- **DIURETICS, THIAZIDE:** May reduce hypoglycemic efficacy
- **ISONIAZID:** May reduce hypoglycemic efficacy
- **MOA INHIBITORS:** May potentiate hypoglycemic effect
- **NIACIN:** May reduce hypoglycemic efficacy
- **PHENOTHIAZINES:** May reduce hypoglycemic efficacy
- **PHENYTOIN:** May reduce hypoglycemic efficacy
- **PROBENECID:** May potentiate hypoglycemic effect
- **SULFONAMIDES:** May displace glipizide from plasma proteins
- **SYMPATHOMIMETIC AGENTS:** May reduce hypoglycemic efficacy
- **THYROID AGENTS:** May reduce hypoglycemic effect
- **WARFARIN:** May displace glipizide from plasma proteins

Doses

■ CATS:

For diabetes mellitus:

- a) In non-ketotic cats that are relatively healthy: Initially monitor weight, urine/glucose/ketones, and several blood glucose measurements. Then give 2.5 mg PO per cat twice daily in conjunction with a meal. After 2 weeks, monitor again and if adverse reactions have not occurred, increase dose to 5 mg twice daily and re-evaluate again in 2 weeks. (Nelson 2000), (Nelson 2005)
- b) 2.5–5 mg per cat PO twice a day when combined with dietary fiber therapy. Evaluate every one to two weeks for a period of 2–3 months. If fasting blood glucose decreases to less than 200 mg/dl, continue at same dosage and reevaluate in 3–6 months. If fasting blood glucose remains greater than 200 mg/dl after 2–3 months, discontinue and institute insulin therapy (Greco 1999); (Greco 2000)
- c) If cat is generally well, weight loss is mild, not ketoacidotic, and does not have peripheral neuropathy, may try glipizide at: 2.5 mg (total dose) PO twice a day. (Daminet 2003)
- d) 5 mg per cat PO twice daily, may decrease dose if hypoglycemia occurs or increase to 7.5 mg (maximum) twice daily if not controlled. Slightly less than 50% of cats may tolerate the drug, have improved clinical signs and blood glucose levels. Response may be delayed, so it should be given for 4–8 weeks before deciding if it was efficacious (owner opinion, body weight, blood glucose determinations over a one-day period every 4 weeks.) (Feldman 2005b)

Monitoring

- Weekly exams during first month of therapy, including PE, body weight, urine glucose/ketones, and several blood glucose exams.
- Adverse effects (anorexia, vomiting, icterus), and occasional liver enzymes and CBC.

Client Information

- Clients should be informed of clinical signs to watch for that would indicate either hypoglycemia or hyperglycemia and be instructed to report these to the veterinarian.
- Compliance with dosing regimen should also be stressed.

Chemistry/Synonyms

A sulfonylurea antidiabetic agent, glipizide (also known as glydi-azinamide) occurs as a whitish powder. It is practically insoluble in water and has pK_a of 5.9.

Glipizide may also be known as: CP-28720, glipizidum, glydiazinamide, or K-4024; many international trade names are available.

Storage/Stability

Tablets should be stored in tight, light-resistant containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Glipizide Tablets: 5 mg, & 10 mg; *Glucotrol*® (Pfizer); generic (Rx)

Glipizide Extended Release Tablets: 2.5 mg, 5 mg, & 10 mg; *Glucotrol XL*® (Pfizer); generic; (Rx)

Glipizide/Metformin Hydrochloride Tablets (film-coated): 2.5 mg/250 mg or 500 mg; 5 mg/500 mg; *Metaglip*® (Bristol-Myers-Squibb); generic (Sandoz); (Rx)

GLUCAGON

(gloo-ka-gon) GlucoGen®

HORMONAL AGENT

Prescriber Highlights

- ▶ Hormone to increase blood glucose that may be useful for treating hypoglycemia in small animals & potentially fatty liver syndrome in dairy cows
- ▶ May be effective in treating beta-blocker or calcium channel overdoses
- ▶ Must be parenterally administered
- ▶ When used as CRI, must be in a setting where blood glucose can be monitored
- ▶ Unlikely to cause adverse effects

Uses/Indications

In small animals, the primary use for glucagon is to increase blood glucose in patients with excessive insulin levels, either endogenously produced (insulinoma) or exogenously administered (insulin overdose). Glucagon has potential in the treatment of fatty liver syndrome in dairy cattle.

In human medicine, glucagon is used in treating the cardiac manifestations of beta-blocker and calcium-channel blocker overdoses. One study (Kerns, D et al. 1997) in dogs, however, demonstrated insulin to be superior to glucagon in treating experimental propranolol overdoses in dogs.

Pharmacology/Actions

Glucagon's main pharmacologic activities are to increase blood glucose and relax smooth muscle of the GI tract. It primarily increases blood glucose by stimulating hepatic glycogenolysis. The mechanisms of action for its GI effects are poorly understood.

Pharmacokinetics

Glucagon must be administered parenterally; it is destroyed in the gut after oral dosing. After intravenous injection, maximum glucose levels are attained within 30 minutes; hyperglycemic effects persist up to 90 minutes after dosing. Glucagon is degraded in the plasma, liver and kidneys; in humans, plasma half-life is around 10 minutes.

Contraindications/Precautions/Warnings

Glucagon should usually not be used in patients with pheochromocytoma as catecholamines may be released leading to hypertension. When used for insulinoma, it must be in a setting where blood glucose can be closely monitored. While glucagon may be useful for blood glucose elevation in insulinoma patients, in humans its use for this is cautioned as it can increase insulin production, leading to greater hypoglycemia once the drug is discontinued.

Adverse Effects

Glucagon is usually well tolerated, but potentially nausea and vomiting could occur after administration. Hypokalemia and hypersensitivity reactions (very rare) are also possible.

Reproductive/Nursing Safety

In humans, glucagon is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) As an endogenously produced hormone, it is unlikely to cause significant risk to offspring.

It is unknown if glucagon enters maternal milk, but it is unlikely to cause harm to nursing offspring.

Overdosage/Acute Toxicity

Adverse effects seen with overdose include nausea, vomiting, diarrhea, gastric hypotonicity and, possibly, hypokalemia. Because glucagon's elimination half-life is so short, treatment may not be necessary and would be symptomatic in nature. If the patient is also receiving beta-blockers, greater increases in blood pressure and heart rate may be seen.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glucagon and may be of significance in veterinary patients:

- **ANTICOAGULANTS:** May have their effects increased when glucagon is concurrently administered; this effect may be delayed. It is suggested to monitor for bleeding and prothrombin activity if glucagon is necessary.

Laboratory Considerations

No glucagon-related laboratory interactions noted.

Doses

■ DOGS:

- a) For hypoglycemic (neuroglycopenic) crises in patients with "insulinomas": 1 mg of glucagon is reconstituted per manufacturer directions and then added to 1000 mL of 0.9% Sodium Chloride; this results in a 1000 ng/mL (nanograms/mL) solution. [Note: Some references state to not mix or dilute with saline solutions, but to use D5W only.] Initially give a 50 ng/kg bolus IV and then administer at a constant rate infusion (CRI) using a suitable pump at a rate of 10–15 ng/kg/minute. May need to increase up to 40 ng/kg/min to maintain euglycemia. (Smith 2002c)

- b) For refractory hypoglycemic patients with insulinoma: Prepare solution as in "a" above. Give at an initial infusion rate of 5 ng/kg/min and increase as needed. (Garrett 2003)

■ CATS:

- a) For hypoglycemic (neuroglycopenic) crises in patients with "insulinomas": 1 mg of glucagon is reconstituted per manufacturer directions and then added to 1000 mL of 0.9% Sodium Chloride; this results in a 1000 ng/mL solution. [Note: Some references state to not mix or dilute with saline solutions, but to use D5W only.] Initially give a 50 ng/kg bolus IV and then administer at a constant rate infusion (CRI) using a suitable pump at a rate of 10–15 ng/kg/minute. May need to increase up to 40 ng/kg/min to maintain euglycemia. (Smith 2002c)

■ CATTLE:

- a) For treatment of fatty liver in early lactation dairy cows older than 3.5 years: 5 mg glucagon in 60 mL of normal saline SC q8h (15 mg/day) for 14 days (Bobe, Ametaj et al. 2003)

Monitoring

- Blood glucose
- Serum potassium if used other than for acute treatment

Client Information

- Glucagon could potentially be used for outpatient emergency initial treatment of hypoglycemia, but oral glucose is probably more appropriate for use by clients.
- Glucagon should be used as a CRI only in a setting where blood glucose can be adequately monitored.

Chemistry/Synonyms

A hormone secreted by the α_2 cells of the pancreas, glucagon is a straight chain polypeptide that contains 29 amino acids whose sequence is consistent throughout mammalian species. It has a molecular weight of 3483. When in crystalline form it is a white- to off-white powder that is relatively insoluble in water at physiologic pH, but is soluble at pH of less than 3 and greater than 9.5. Glucagon may be expressed in terms of International Units (IU) or by weight. One IU is equivalent to one milligram of glucagon. Commercially available glucagon is now obtained via recombinant DNA sources.

Glucagon may also be known as glucagonum or HGF, and *GlucaGen*®.

Storage/Stability/Compatibility

The commercially available powder for reconstitution should be stored at room temperature between 20–25°C (68–77°F); avoid freezing and protect from light. Once reconstituted with the supplied diluent the solution should be clear with a water-like consistency and used immediately; any unused portion should be discarded. If the solution contains any gel formation or particles, it should be discarded.

To prepare glucagon for a continuous rate infusion, dilute 1 mg with the supplied diluent or sterile water; roll gently until dissolved, this may then be further diluted in D5W. May be given through a Y-tube or 3-way stopcock if a dextrose solution is running.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Glucagon powder for Injection: 1 mg (1 unit) with 1 mL diluent in vials & syringes; *GlucaGen*® Diagnostic Kit & *GlucaGen* HypoKit® (Novo Nordisk); *Glucagon Emergency Kit*® (Eli Lilly); (Rx)

GLUCOCORTICOID AGENTS, GENERAL INFORMATION

Glucocorticoid Comparison Table

DRUG	EQUIV. ANTI-INFLAMMATORY DOSE (MG)	RELATIVE ANTI-INFLAMMATORY POTENCY	RELATIVE MINERAL-CORTICOID ACTIVITY	PLASMA HALF-LIFE DOGS (MIN) [HUMANS]	DURATION OF ACTION AFTER ORAL/IV [IM]
Hydrocortisone (Cortisol)	20	1	1–2	52–57 [90]	<12 hrs
Betamethasone Sod. Succ./Sod. Phos.	0.6	25	0	[300+]	>48 hrs
Dexamethasone Sod. Succ./Sod. Phos.	0.75	30	0	119–136 [200–300+]	>48 hrs
Flumethasone	1.5	15–30	?	?	
Isoflupredone		17			
Methylprednisolone	4	5	0	91 [200]	12–36 hrs
Prednisolone	5	4	1	69–197 [115–212]	12–36 hrs
Prednisone	5	4	1	[60]	12–36 hrs
Triamcinolone Acetonide	4	5	0	[200+]	12–36 hrs [weeks]

Uses/Indications

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. **1)** Replacement of glucocorticoid activity in patients with adrenal insufficiency, **2)** as an antiinflammatory agent, and **3)** as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete. For specific dosages and indications refer to the Doses section for each glucocorticoid drug monograph.

Pharmacology/Actions

Glucocorticoids have effects on virtually every cell type and system in mammals. An overview of the effects of these agents follows:

Cardiovascular System: Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A relatively clinically insignificant positive inotropic effect can occur after glucocorticoid administration. Increased blood pressure can result from both the

drugs' vasoconstrictive properties and increased blood volume that may be produced.

Cells: Glucocorticoids inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes and the cellular response to mediators of inflammation. Glucocorticoids stabilize lysosomal membranes.

CNS/Autonomic Nervous System: Glucocorticoids can lower seizure threshold, alter mood and behavior, diminish the response to pyrogens, stimulate appetite and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.

Endocrine System: When animals are not stressed, glucocorticoids will suppress the release of ACTH from the anterior pituitary, thereby reducing or preventing the release of endogenous corticosteroids. Stress factors (e.g., renal disease, liver disease, diabetes) may sometimes nullify the suppressing aspects of exogenously administered steroids. Release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin, and luteinizing hormone (LH) may all be reduced when glucocorticoids are administered at pharmacological doses. Conversion of thyroxine (T₄) to triiodothyronine (T₃) may be reduced by glucocorticoids; and plasma levels of parathyroid hormone increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (ADH) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin-receptors and the post-receptor effects of insulin.

Hematopoietic System: Glucocorticoids can increase the numbers of circulating platelets, neutrophils and red blood cells, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes and eosinophils are seen as glucocorticoids can sequester these cells into the lungs and spleen and prompt decreased release from the bone marrow. Removal of old red blood cells becomes diminished. Glucocorticoids can cause involution of lymphoid tissue.

GI Tract and Hepatic System: Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased while fat absorption is increased. Hepatic changes can include increased fat and glycogen deposits within hepatocytes, increased serum levels of alanine aminotransferase (ALT), and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum alkaline phosphatase levels. Glucocorticoids can cause minor increases in BSP (bromosulfophthalein) retention time.

Immune System (also see Cells and Hematopoietic System): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; inhibit phagocytosis and chemotaxis; antigen processing; and diminish intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high or very high doses and there are species differences in response.

Metabolic effects: Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (e.g., abdomen) and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glycerol are increased. Protein is mobilized from most areas of the body (not the liver).

Musculoskeletal: Glucocorticoids may cause muscular weakness (also caused if there is a lack of glucocorticoids), atrophy, and os-

teoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.

Ophthalmic: Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.

Renal, Fluid, & Electrolytes: Glucocorticoids can increase potassium and calcium excretion, sodium and chloride reabsorption, and extracellular fluid volume. Hypokalemia and/or hypocalcemia rarely occur. Diuresis may develop following glucocorticoid administration.

Skin: Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended and alopecia may occur.

Contraindications/Precautions/Warnings

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison's), when administered IM in patients with idiopathic thrombocytopenia, and in patients hypersensitive to a particular compound. Use of sustained-release injectable glucocorticoids is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically, other than with "burst" therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a "stressor" (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally manifest as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU) may all be seen with short-term "burst" therapy as well as with alternate-day maintenance therapy on days when the drug is given. Adverse effects in dogs can include: dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with short-term antiinflammatory therapy occur relatively uncommonly. Adverse effects associated with immunosuppressive doses are more common and potentially more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to "Cushingoid" effects, however.

Administration of dexamethasone or triamcinolone may play a role in the development of laminitis in horses.

Reproductive/Nursing Safety

Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production,

myelin, retinal, pancreatic, and mammary development. Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy.

Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns. In humans, several studies suggest that amounts excreted in human breast milk are negligible with prednisone or prednisolone doses of 20 mg/day or less, or methylprednisolone doses less than or equal to 8 mg/day. Large doses for short periods may not harm the infant. Waiting 3–4 hours after the dose before nursing and using prednisolone rather than prednisone may result in a lower corticosteroid dose to offspring.

Overdosage/Acute Toxicity

Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glucocorticoids and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** When administered concomitantly with glucocorticoids may cause hypokalemia
- **ANTICHOLINESTERASE AGENTS** (e.g., **pyridostigmine**, **neostigmine**, etc.): In patients with myasthenia gravis, concomitant glucocorticoid with these agents may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration.
- **ASPIRIN (salicylates):** Glucocorticoids may reduce salicylate blood levels
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may also inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required.
- **CYCLOSPORINE:** Concomitant administration of may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; clinical significance of this interaction is not clear
- **DIGOXIN:** Secondary to hypokalemia, increased risk for arrhythmias
- **DIURETICS, POTASSIUM-DEPLETING (furosemide, thiazides):** When administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE:** May increase metabolism
- **ESTROGENS:** The effects of hydrocortisone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN:** Requirements may increase in patients receiving glucocorticoids
- **KETOCONAZOLE:** May decrease metabolism
- **MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDS:** Administration of other ulcerogenic drugs with glucocorticoids may increase risk

- **PHENOBARBITAL:** May increase the metabolism of glucocorticoids
- **PHENYTOIN:** May increase the metabolism of glucocorticoids
- **RIFAMPIN:** May increase the metabolism of glucocorticoids
- **VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids

Laboratory Considerations

- Glucocorticoids may increase serum **cholesterol** and **urine glucose** levels.
- Glucocorticoids may decrease serum **potassium**.
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T₃** & **T₄** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of ¹³¹I by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids.
- False-negative results of the **nitroblue tetrazolium test for systemic bacterial infections** may be induced by glucocorticoids.

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

Client Information

- Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting with veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects progress or become severe.

GLUCOSAMINE/CHONDROITIN SULFATE

(gloo-kose-a-meen/kon-droy-tin sul-fayt) Cosequin®

NUTRITIONAL SUPPLEMENT

Prescriber Highlights

- ▶ So-called nutraceutical that can be used as an adjunctive treatment for osteoarthritis or other painful conditions in horses, cats, dogs, etc; FLUTD in cats
- ▶ Well tolerated, but efficacy is uncertain
- ▶ Not a regulated drug; choose products carefully; large variation in commercially available products

Uses/Indications

These compounds may be useful in treating osteoarthritis or other painful conditions in domestic animals, but large, well-designed controlled clinical studies proving efficacy were not located. One study in dogs (McCarthy, O'Donovan et al. 2007) showed some positive effect, but this study was not placebo controlled and compared responses versus carprofen. Another placebo-controlled, blinded study in dogs (Moreau, Dupuis et al. 2003), did not demonstrate statistically significant improvement after 60 days of treatment.

These compounds potentially could be of benefit in cats with FLUTD (feline lower urinary tract disease) because of the presence of glycosaminoglycans as part of the protective layer of the urinary tract. Controlled studies have shown some positive effects in some cats, but overall did not appear to make a significant difference.

Pharmacology/Actions

Cartilage cells use glucosamine to produce glycosaminoglycans and hyaluronan. Glucosamine also regulates synthesis of collagen and proteoglycans in cartilage and has mild antiinflammatory effects due to its ability to scavenge free radicals. Chondrocytes normally produce ample quantities of glucosamine from glucose and amino acids, but this ability may diminish with age, disease, or trauma. Exogenously administered glucosamine appears to be able to be utilized by chondrocytes.

Chondroitin sulfate possesses several pharmacologic effects. It appears to inhibit destructive enzymes in joint fluid and cartilage. Thrombi formation in microvasculature may be reduced. In joint cartilage, it stimulates the production of glycosaminoglycans and proteoglycans.

While *in vitro* evidence exists, there is not solid evidence that using these compounds together improves clinical effect over either alone, but *in vivo* studies are ongoing.

Pharmacokinetics

The pharmacokinetics of these compounds are hard to evaluate due to the different salts, lack of standards, etc. Both glucosamine HCl and glucosamine sulfate are absorbed in the gut after the salt is cleaved in the stomach. There exists controversy as to whether either salt of glucosamine is superior to the other. Theoretically, if the amount of glucosamine base contained in the product is equivalent, the amount absorbed should be as well. Most clinical studies in veterinary species have been done with the HCl salt. Purified, low molecular weight chondroitin appears to be absorbed from the gut. Reported bioavailability in horses for chondroitin sulfate is about 25%; glucosamine, about 2%; bioavailability in dogs is reportedly about 5% for chondroitin sulfate and 12% for glucosamine.

Onset of any clinical efficacy may require 2–6 weeks of treatment.

Contraindications/Precautions/Warnings

No absolute contraindications were located for these compounds. As hypersensitivity reactions are a theoretical possibility, animals demonstrating prior hypersensitivity reactions to these compounds should not receive them.

In humans, glucosamine may exacerbate symptoms associated with asthma. Although this has not yet been reported in veterinary patients, caution is advised in patients with bronchoconstrictive conditions.

Adverse Effects

These products appear to be very well tolerated in dogs, cats, and horses. Adverse effects could potentially include some minor gastrointestinal effects (flatulence, stool softening). Since these products are often derived from natural sources, hypersensitivity reactions could occur.

Reproductive/Nursing Safety

No studies on the safety of these compounds in pregnant or lactating animals have been performed.

Overdosage/Acute Toxicity

Oral overdosage is unlikely to cause significant problems. The LD₅₀ for the combined compound in rats is greater than 5 g/kg. Gastrointestinal effects may result. Changes in coagulation parameters could occur, but have not been documented to date.

Products that contain manganese could lead to manganese toxicity if given in very high dosages (above label recommendations) chronically.

Drug Interactions

No clinically significant drug interactions have been reported to date. By reducing **doxorubicin** or **etoposide** inhibition of topoisomerase II, glucosamine may induce resistance to these agents. High dose chondroitin sulfate and/or glucosamine potentially could enhance the effects of **warfarin**, **heparin**, or other drugs that affect coagulation. Again, clinically significant interactions with either of these compounds have not been confirmed.

Laboratory Considerations

- High dose chondroitin and glucosamine theoretically could increase International Normalized Ratio (**INR**) in patients taking warfarin.

Doses

Note: Because of the variability in products available, it is recommended to choose a product that has been tested in the species for which it is marketed; consult the product label.

■ DOGS:

- For adjunctive treatment of chronic pain: Glucosamine/chondroitin: 13–15 mg/kg (of the chondroitin component) PO once daily (q24h). (Hardie, Lascelles et al. 2003)
- For adjunctive treatment of cancer pain: Glucosamine/chondroitin: 15–30 mg/kg (of the chondroitin component) PO once daily (q24h) for 4–6 weeks then half the dose. (Lascelles 2003)
- For adjunctive treatment of chronic pain: Glucosamine/chondroitin: 13–15 mg/kg (of the chondroitin component) PO once daily or every other day (q24–48h). (Hansen 2003b)
- Label Recommendation as a Dietary Supplement for *Cosequin*®:

For **Small Dogs** (under 25 lbs): Initially, using Regular Strength capsules for cats and small dogs: under 10 lb.: ½ to 1 capsule daily; 10–24 lb.: 2 capsules daily (1 in AM/ 1 in PM). Maintenance Administration (after initial 4–6 week period): under 10 lb. can often have their dosage reduced to ½ capsule daily or 1 capsule every other day. 10 to 24 lb. can often have their dosage reduced to 1 capsule daily.

For **Medium and Large Dogs** (>25 lbs.): Initially, using *Cosequin*®DS (double strength) tablets or capsules: 25–49 lb.: 2 capsules daily (1 in AM/ 1 in PM); 50–100 lb.: 3 capsules daily (2 in AM/ 1 in PM); over 100 lb.: 4 capsules daily (2 in AM/ 2 in PM). Maintenance Administration (after initial 4–6 week period): dogs can have their total daily dosage gradually lowered until maintenance level is reached.

Amount can be increased at any time depending on the pet's needs. Tablets can be given as a treat or crumbled and mixed with the pet's food. The capsules can be pulled apart and the contents sprinkled on the pet's food. Wet or moist food works best. As an alternative, pets can be pill or the

capsules administered by wrapping in a small piece of food. (Label recommendations; *Cosequin*®—Nutramax)

■ CATS:

- For adjunctive treatment of cancer pain: Glucosamine/chondroitin: 15–30 mg/kg (of the chondroitin component) PO once daily (q24h) for 4–6 weeks then half the dose. (Lascelles 2003)
- For adjunctive treatment of chronic pain: Glucosamine/chondroitin: 15–20 mg/kg (of the chondroitin component) PO once daily or every other day (q24–48h). (Hansen 2003b)
- Label Recommendation as a Dietary Supplement for *Cosequin*® For Cats: Initially: under 10 lb.: 1 capsule sprinkled on food daily; over 10 lb.: 2 capsules sprinkled on food daily (1 in AM/ 1 in PM). Maintenance Administration (after initial 4–6 week period): once desired response is obtained, capsules may be administered every other day.

Number of capsules can be increased at any time depending on the pet's needs. The capsules contain a flavored powder. The capsules should be opened and the contents mixed with or sprinkled over the food. Dry food may be moistened with a small amount of water so that the powder sticks. Alternatively, the contents of the capsules may be mixed with a small amount (*i.e.*, tablespoon) of wet or moist food. As an alternative, cats can be pill. (Label recommendations; *Cosequin*® For Cats—Nutramax)

■ HORSES:

- For navicular syndrome: Using *Cosequin*® Concentrated Powder labeled for horses: 16.5 grams (5 scoops) in feed twice daily. (Hanson, Brawner et al. 2001)
- Label Recommendation as a Dietary Supplement for *Cosequin*® Concentrated Powder: Initially: for horses under 600 lb., 2 scoops in AM and 2 scoops in PM; horses 600–1,200 lb., 3 scoops in AM and 3 scoops in PM; horses over 1,200 lb., 4 scoops in AM and 4 scoops in PM. The initial administration period is 2 to 4 weeks; if horse shows little or no response, extend initial amount for two more weeks.

Transition Period: Do not lower amount until horse has begun to respond. After achieving a good response, reduce total daily amount by one level scoop each week. Gradually reducing the amount will help find an individual maintenance level. Suggested Maintenance Administration: horses under 600 lb., 1 scoop daily; horses 600–1,200 lb., 1–2 scoops daily; horses over 1,200 lb., 2 scoops daily. Amount can be increased at any time.

May be top dressed on sweet feed. Add a small amount of water or molasses to get the powder to stick to dry feed. (Label and insert recommendations; *Cosequin*® Concentrated Powder—Nutramax Labs)

Monitoring

- Clinical efficacy

Client Information

- Onset of any clinical improvement may require 2–6 weeks of treatment.
- Do not switch brands from that prescribed without first contacting your veterinarian.
- Side effects are unlikely, but mild gastrointestinal upset has been reported in small animals. Should this be troublesome, contact your veterinarian.

Chemistry/Synonyms

Glucosamine is most often available as either glucosamine HCl or glucosamine sulfate. It is an amino sugar that is synthesized *in vivo* by animal cells from glucose and glutamine.

Glucosamine (HCl or Sulfate) may also be known as: chitosamine, NSC-758, 2-amino-2-deoxy-beta-D-glucopyranose, G6SD-glucosamine, glucose-6-phosphate, or amino monosaccharide.

Chondroitin sulfate is an acid mucopolysaccharide/glycosaminoglycan that is found in most cartilaginous tissues. It is a long chain compound that contains units of galactosamine and glucuronic acid.

Chondroitin sulfate may also be known as chondroitin 4-sulfate, chondroitin sulfate A, chondroitin sulfate B, chondroitin sulfate C, chondroitin sulfate sodium, CSA, sodium chondroitin sulfate, chondroitin polysulfate, CDA, CSCSC, GAG, or galactosaminoglycan sulfate.

Storage/Stability

Because of the multiple products and product formulations available, check label for storage and stability (expiration date) information. Chondroitin sulfate is an extremely hygroscopic compound and, generally, these products should be stored in tight containers at room temperature. Avoid storing in direct sunlight.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None as pharmaceuticals. Supplements are available from a wide variety of sources and dosage forms include tablets, capsules and powder in a variety of concentrations. There are specific products marketed for use in animals, including *Cosequin*®, *Restor-A-Flex*®, *OsteO-3*®, *Arthri-Nu*®, *ProMotion*®, *Seraquin*®, *Oste-O-Guard*®, *Caniflex*®, *Equi-Phar Flex*®, etc.

Glucosamine and chondroitin sulfate are considered nutritional supplements by the FDA. No standards have been accepted for potency, purity, safety or efficacy by regulatory bodies.

Bioequivalence between products cannot be assumed and independent analysis has shown a wide variation in products.

HUMAN-LABELED PRODUCTS: None as pharmaceuticals

GLUTAMINE

(gloo-ta-meen)

NUTRITIONAL

Prescriber Highlights

- ▶ Amino acid that may be useful in preventing/treating GI epithelium damage
- ▶ Little documentation for efficacy, but adverse effects unlikely

Uses/Indications

Glutamine has been used as a GI protectant and in an attempt to enhance GI healing in conditions where GI epithelium is damaged (Parvo enteritis, chemotherapy, etc.).

A study that evaluated the efficacy of glutamine supplementation in cats with methotrexate-induced enteritis found no difference between cats supplemented with glutamine and those that were not. (Marks, Cook et al. 1999)

Pharmacology/Actions

Glutamine is a conditionally essential amino acid that is produced primarily in skeletal muscle and then released into the circulation. Glutamine is required for proper function of the immune system, GI tract, kidneys, and liver. Glutamine also serves as a precursor for glutathione, glutamate, purines, pyrimidines, and other amino acids.

Glutamine's effects on the gastrointestinal tract are one of the primary areas of interest for its therapeutic use as an exogenously administered drug. When the body is under severe stress, it consumes more glutamine than it can produce and progressive muscle wasting occurs as it tries to meet glutamine requirements. There is some evidence that glutamine may have a role in intestinal cell proliferation and determination. When glutamine is depleted, intestinal epithelium can atrophy, ulcerate, or become necrotic. In patients undergoing cancer chemotherapy or radiotherapy, diminished glutamine levels in the gastrointestinal tract can cause increased GI toxicity. Supplementation of exogenous glutamine may help protect the GI from these effects.

Pharmacokinetics

Little information was located outside of what is described in the pharmacology section.

Contraindications/Precautions/Warnings

Because it is partially metabolized into ammonia and glutamate, use with caution in patients with severe hepatic insufficiency, severe behavior disorders or epilepsy.

Adverse Effects

Glutamine is well tolerated when used orally or intravenously. Potentially, it may have some CNS effects at high dosages.

Reproductive/Nursing Safety

There is insufficient data available documenting the safe use of glutamine during pregnancy or nursing.

Overdosage/Acute Toxicity

Overdosages are unlikely to be harmful. Doses of up to 40 grams per day IV have been tolerated in humans without ill effects. Because glutamine is partially metabolized to ammonia, patients with hepatic insufficiency may be adversely affected.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glutamine and may be of significance in veterinary patients:

- **ANTICONSULSANT MEDICATIONS:** Glutamine could potentially affect the efficacy of antiseizure medications (**phenobarbital**, **potassium bromide**, etc.). It is partially converted into glutamate, which can act as an excitatory neurotransmitter.
- **LACTULOSE:** Theoretically, glutamine may antagonize the effects of lactulose in patients with hepatic encephalopathy.

Laboratory Considerations

- Glutamine may increase **serum ammonia** or **glutamate** levels.

Doses

■ DOGS & CATS:

For adjunctive treatment of GI inflammatory conditions:

- a) 0.5 grams/kg PO daily (Wynn 2002)
- b) 0.5 gram/kg/day PO divided twice a day in the water or food. (Silverstein 2003)

Monitoring

- Efficacy

Client Information

- May be administered with food.

Chemistry/Synonyms

Glutamine is an aliphatic amino acid. It occurs as white crystals or crystalline powder and is soluble in water and practically insoluble in alcohol.

Glutamine may also be known as: glutamic acid, GLN, glutamate, glutamate, levoglutamide, levoglutamine, L-glutamic acid, L-glutamic acid 5-amide, l-glutamine, L-glutamine, and Q.

Storage/Stability/Compatibility

Glutamine tablets and powder should be stored in tight containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Glutamine is considered a nutrient. Glutamine may be purchased as L-glutamine 500 mg tablets, glutamine powder, or glutamic acid in 500 mg tablets, powder. Glutamic acid is rapidly degraded in the body to glutamine. Parenteral forms of glutamate may be available in other countries.

GLYBURIDE

(glye-byoor-ide) DiaBeta®, Micronase®

SULFONYLUREA ANTIDIABETIC AGENT

Prescriber Highlights

- ▶ Human oral antidiabetic agent (Type II) that may be useful in cats
- ▶ Glipizide used more often; glyburide may be useful if glipizide unavailable or if once a day dosing is important
- ▶ Contraindications: Severe burns, severe trauma, severe infection, diabetic coma or other hypoglycemic conditions, major surgery, ketosis, ketoacidosis or other significant acidotic conditions
- ▶ Caution: Untreated adrenal or pituitary insufficiency; thyroid, renal, or hepatic function impairment; prolonged vomiting; high fever; malnourishment or debilitated condition
- ▶ Adverse Effects: CATS: GI (i.e., vomiting), hypoglycemia, liver toxicity
- ▶ Drug interactions
- ▶ Do not confuse glipizide, glimepiride & glyburide

Uses/Indications

Glyburide is an alternative oral treatment for non-insulin dependent diabetes mellitus (NIDDM) in cats, particularly if glipizide is unavailable or if twice daily administration of glipizide is not tolerated (by cat or owner).

Pharmacology/Actions

Like glipizide and other oral sulfonylureas, glyburide lowers blood glucose concentrations in both diabetic and normal patients. While

it is unknown how glyburide precisely lowers glucose, it initially stimulates secretion of endogenous functional beta cells in the pancreas. It also may enhance insulin activity at post receptor sites and reduce basal hepatic glucose production that may explain its effectiveness with long-term administration.

Pharmacokinetics

Glyburide appears to be well absorbed but bioavailability data is lacking. Food apparently does not have an effect on the absorptive characteristics of the drug. Glyburide is distributed throughout the body, including into the brain and across the placenta. Glyburide is apparently completely metabolized, presumably in the liver. Metabolites are excreted in both the feces and the urine. While its elimination half-life in cats is not known, once a day dosing appears to be effective in cats with NIDDM.

Contraindications/Precautions/Warnings

Oral antidiabetic agents are considered contraindicated with the following conditions: severe burns, severe trauma, severe infection, diabetic coma or other hypoglycemic conditions, major surgery, ketosis, ketoacidosis or other significant acidotic conditions. Glyburide should only be used when its potential benefits outweigh its risks in patients with untreated adrenal or pituitary insufficiency; thyroid, renal, or hepatic function impairment; prolonged vomiting; high fever; malnourishment or in debilitated condition.

Some patients with type II diabetes may have their disease complicated by the production of excessive amounts of cortisol or growth hormone that may antagonize insulin's effects. These causes should be ruled out before initiating oral antidiabetic therapy.

Adverse Effects

Experience with glyburide is limited in veterinary medicine. Hypoglycemia, vomiting, icterus, and increased ALT (SGPT) levels are all potentially possible. Should toxicity develop, reinstitution of drug therapy may be attempted at a lower dosage after clinical signs resolve.

Other adverse effects that are possible (noted in humans) include: allergic skin reactions, arthralgia, bone marrow suppression, or cholestatic jaundice.

Glyburide may not be effective in cats demonstrating insulin resistance.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is unknown if glyburide is excreted in milk.

Overdosage/Acute Toxicity

Profound hypoglycemia is the greatest concern after an overdose. In humans, severe hypoglycemia has occurred at relatively low dosages. Gut emptying protocols should be employed when warranted. Because its half-life is longer than glipizide, prolonged hypoglycemia may occur and blood glucose monitoring and treatment with parenteral glucose may be required for several days. Massive overdoses may also require additional monitoring (blood gases, serum electrolytes) and supportive therapy.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glyburide and may be of significance in veterinary patients:

- **ALCOHOL:** A disulfiram-like reaction (anorexia, nausea, vomiting) is possible

- **ANTIFUNGALS, AZOLE (ketoconazole, itraconazole, fluconazole):** May increase plasma levels of glyburide
- **BETA-BLOCKERS:** May potentiate hypoglycemic effect
- **CHLORAMPHENICOL:** May displace glyburide from plasma proteins
- **CIMETIDINE:** May potentiate hypoglycemic effect
- **CORTICOSTEROIDS:** May reduce efficacy
- **DIURETICS, THIAZIDE:** May reduce hypoglycemic efficacy
- **ISONIAZID:** May reduce hypoglycemic efficacy
- **MOA INHIBITORS:** May potentiate hypoglycemic effect
- **NIACIN:** May reduce hypoglycemic efficacy
- **PHENOTHIAZINES:** May reduce hypoglycemic efficacy
- **PHENYTOIN:** May reduce hypoglycemic efficacy
- **PROBENECID:** May potentiate hypoglycemic effect
- **SULFONAMIDES:** May displace glyburide from plasma proteins
- **SYMPATHOMIMETIC AGENTS:** May reduce hypoglycemic efficacy
- **THYROID AGENTS:** May reduce hypoglycemic effect
- **WARFARIN:** May displace glyburide from plasma proteins

Doses

■ CATS:

For NIDDM:

- a) Initial dose at 0.625 mg (½ of a 1.25 mg tablet) PO once daily (Nelson 2000)
- b) If cat is generally well, weight loss is mild, is not ketoacidotic, and does not have peripheral neuropathy, may try glyburide at: 2.5 mg (total dose) PO twice a day (Daminet 2003)

Monitoring

- Weekly exams during first month of therapy including PE, body weight, urine glucose/ketones and several blood glucose exams.
- Adverse effects (vomiting, icterus), and occasional liver enzymes and CBC.

Client Information

- Clients should be informed of clinical signs to watch for that would indicate either hypoglycemia or hyperglycemia and be instructed to report these to the veterinarian.
- Compliance with dosing regimen should also be stressed.

Chemistry/Synonyms

An oral sulfonylurea antidiabetic agent, glyburide occurs as a white or nearly white, odorless or almost odorless, crystalline powder. As pH increases, solubility increases. At a pH of 4, solubility in water is about 4 mcg/mL and at a pH of 9, 600 mcg/mL. Glyburide has a pKa of 6.8.

Glyburide may also be known as: glibenclamide, glibenclamidum, glybenclamide, glybenzcyclamide, HB-419, and U-26452; many trade names are available.

Storage/Stability

Glyburide oral tablets should be stored in well-closed containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Glyburide Tablets: 1.25 mg, 2.5 mg, & 5 mg; micronized tablets: 1.5 mg, 3 mg, 4.5 mg and 6 mg; *Micronase®* & *Glynase® PresTab* (Pharmacia & Upjohn); *DiaBeta®* (Hoechst Marion Roussel); generic; (Rx)

Glyburide/Metformin HCl Tablets: 1.25 mg/250 mg, 2.5 mg/500 mg and 5 mg/500 mg; *Glucovance®* (Bristol-Myers Squibb); generic (PAR); (Rx)

GLYCERIN, ORAL

(gli-ser-in) Osmoglyn®

OSMOTIC AGENT

Prescriber Highlights

- Oral osmotic that reduces intraocular & CSF pressure
- **Contraindications:** Patients with known hypersensitivity, anuria (well established), severe dehydration, severe cardiac decompensation, acute pulmonary edema.
- **Caution:** Hypovolemia, cardiac disease, or diabetes
- **Adverse Effects:** Vomiting (most common)

Uses/Indications

Oral glycerin is used primarily for the short-term reduction of IOP in small animals with acute glaucoma. It may also be considered for use to reduce increased CSF pressure.

The IOP-lowering effect of glycerin may be more variable than with mannitol, but since it may be given orally, it may be more advantageous to use in certain cases.

Pharmacology/Actions

Glycerin in therapeutic oral doses increases the osmotic pressure of plasma so that water from extracellular spaces is drawn into the blood. This can decrease intraocular pressure (IOP). The amount of decrease in IOP is dependent upon the dose of glycerin, and the cause and extent of increased IOP. Glycerin also decreases extracellular water content from other tissues and can cause dehydration and decreased CSF pressure.

Pharmacokinetics

Glycerin is rapidly absorbed from the GI tract; peak serum levels generally occur within 90 minutes and maximum decreases in IOP usually occur within an hour of dosing and persist for up to 8 hours. Glycerin is distributed throughout the blood and is primarily metabolized by the liver. About 10% of the drug is excreted unchanged in the urine. Serum half-life in humans is about 30–45 minutes.

Contraindications/Precautions/Warnings

Glycerin is contraindicated in patients hypersensitive to it. It is also contraindicated in patients with well-established anuria, that are severely dehydrated, severely cardiac decompensated, or with frank or impending acute pulmonary edema.

Glycerin should be used with caution in animals when the blood:ocular barrier is not intact (hyphema, uveitis), and those with hypovolemia, cardiac disease, or diabetes. Acute urinary retention should be avoided during the preoperative period.

Adverse Effects

Vomiting after dosing is the most common adverse effect seen with glycerin use. In humans, headache, nausea, thirst, and diarrhea have also been reported.

Reproductive/Nursing Safety

The safety of this drug in pregnant animals is unknown; use only when potential benefits outweigh the risks of therapy. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

No specific information on glycerin was located for lactation safety.

Overdosage/Acute Toxicity

No specific information was located, but cardiac arrhythmias, non-ketotic hyperosmolar coma, and severe dehydration have been reported with the drug.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving glycerin and may be of significance in veterinary patients:

- **CARBONIC ANHYDRASE INHIBITORS** (e.g., **acetazolamide**, **dichlorophenamide**): Concomitant administration of carbonic anhydrase inhibitors or topical miotic agents may prolong the IOP-reducing effects of glycerin.
- **MIOTIC AGENTS, TOPICAL**: Concomitant administration topical miotic agents may prolong the IOP-reducing effects of glycerin

Doses

■ DOGS & CATS:

For acute glaucoma:

- a) 1–2 mL/kg (of 50% solution); may repeat in 8 hours if necessary; withhold water for 30–60 minutes after administration (Brooks 1986), (Brooks 1990)
- b) 1–2 g/kg PO (Herring 2003)
- c) 1–2 mL/kg (of a 90% solution) PO usually as a single dose; withhold water for 3–4 hours after administration. Author uses glycerin often because it is quicker and easier to administer than mannitol and is usually effective. (Collins 2006)

Monitoring

- IOP
- Urine output
- Hydration status

Chemistry/Synonyms

A trihydric alcohol, glycerin occurs as clear, sweet-tasting, syrupy, hygroscopic liquid that has a characteristic odor. It is miscible with water and alcohol, but not miscible in oils. Glycerin solutions are neutral to litmus.

Glycerin may also be known as: E422, glycerol, glycerol, glycerin, glycerine, and glycerolum; many trade names are available.

Storage/Stability

Glycerin oral solution should be stored in tight containers at room temperature; protect from freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None for systemic use.

HUMAN-LABELED PRODUCTS:

Glycerin Oral Liquid: 50% (0.6 g glycerin/mL) in 220 mL; *Osmoglyn*® (Alcon); (Rx)

Glycerin is also available in a topical ophthalmic solution and as suppositories or liquid for rectal laxative use. USP glycerin 90% could be used for oral use in small animals (see doses above).

Glyceryl Guaiacolate; GG—see Guaifenesin

GLYCOPYRROLATE

(glye-koe-pye-roe-late) Robinul®

ANTICHOLINERGIC (ANTIMUSCARINIC)

Prescriber Highlights

- Synthetic antimuscarinic agent similar to atropine available both orally & parenterally; used for a variety of indications (bradycardia, premed, antidote, etc.)
- Contraindicated in conditions where anticholinergic effects would be detrimental (e.g., narrow angle glaucoma, tachycardias, ileus, urinary obstruction, etc.)
- Adverse effects are dose related & anticholinergic in nature, including: dry secretions; initial bradycardia, then tachycardia; slowing of gut & urinary tract motility; mydriasis/cycloplegia
- Drug interactions

Uses/Indications

Glycopyrrolate injection is approved for use in dogs and cats. The FDA approved indication for these species is as a preanesthetic anticholinergic agent. The drug is also used to treat sinus bradycardia, sinoatrial arrest, and incomplete AV block, where anticholinergic therapy may be beneficial. When cholinergic agents such as neostigmine or pyridostigmine are used to reverse neuromuscular blockade due to non-depolarizing muscle relaxants, glycopyrrolate may be administered simultaneously to prevent the peripheral muscarinic effects of the cholinergic agent.

Pharmacology/Actions

An antimuscarinic with similar actions as atropine, glycopyrrolate is a quaternary ammonium compound and, unlike atropine, does not cross appreciably into the CNS. It, therefore, should not exhibit the same extent of CNS adverse effects that atropine possesses. For further information, refer to the atropine monograph.

Pharmacokinetics

Quaternary anticholinergic agents are not completely absorbed after oral administration, but quantitative data reporting the rate and extent of absorption of glycopyrrolate is not available. In dogs, following IV administration, the onset of action is generally within one minute. After IM or SC administration, peak effects occur approximately 30–45 minutes post injection. The vagolytic effects persist for 2–3 hours and the antisialagogue (reduced salivation) effects persist for up to 7 hours. After oral administration, the anticholinergic effects of glycopyrrolate may persist for 8–12 hours.

Little information is available regarding the distributory aspects of glycopyrrolate. Being a quaternary ammonium compound, glycopyrrolate is completely ionized; therefore, it has poor lipid solubility and does not readily penetrate into the CNS or eye.

Glycopyrrolate crosses the placenta only marginally; it is unknown if it is excreted into milk.

Glycopyrrolate is eliminated rapidly from the serum after IV administration and virtually no drug remains in the serum 30 minutes to 3 hours after dosing. Only a small amount is metabolized and the majority is eliminated unchanged in the feces and urine.

Contraindications/Precautions/Warnings

One manufacturer (Fort Dodge) of the veterinary product lists contraindications to glycopyrrolate's use in dogs and cats hypersensitive to it and that it should not be used in pregnant animals.

However, it would be prudent to refer to the recommendations listed in the atropine monograph regarding contraindications and precautions.

Adverse Effects

With the exceptions of rare CNS adverse effects and being slightly less arrhythmogenic, glycopyrrolate can be expected to have a similar adverse effect profile as atropine. The manufacturer of the veterinary product (Fort Dodge) lists only mydriasis, tachycardia, and xerostomia as adverse effects in dogs and cats at the doses they recommend. For more information, refer to the atropine monograph.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

No specific lactation safety information was found; however, it is unlikely to be excreted into milk in substantial quantities because of its quaternary structure.

Overdosage/Acute Toxicity

In dogs, the LD₅₀ for glycopyrrolate is reported to be 25 mg/kg IV. Doses of 2 mg/kg IV daily for 5 days per week for 4 weeks demonstrated no signs of toxicity. In the cat, the LD₅₀ after IM injection is 283 mg/kg. Because of its quaternary structure, it would be expected that minimal CNS effects would occur after an overdose of glycopyrrolate when compared to atropine. See the information listed in the atropine monograph for more information.

Drug Interactions

Glycopyrrolate would be expected to have a similar drug interaction profile as atropine. The following drug interactions have either been reported or are theoretical in humans or animals receiving atropine or glycopyrrolate and may be of significance in veterinary patients:

The following drugs may enhance the activity or toxicity of atropine and its derivatives:

- **AMANTADINE**
- **ANTICHOLINERGIC AGENTS** (other)
- **ANTICHOLINERGIC MUSCLE RELAXANTS**
- **ANTI-HISTAMINES** (e.g., diphenhydramine)
- **DISOPYRAMIDE**
- **MEPERIDINE**
- **PHENOTHIAZINES**
- **PROCAINAMIDE**
- **PRIMIDONE**
- **TRICYCLIC ANTIDEPRESSANTS** (e.g., amitriptyline, clomipramine)
- **AMITRAZ:** Atropine may aggravate some signs seen with amitraz toxicity; leading to hypertension and further inhibition of peristalsis
- **ANTACIDS:** May decrease PO atropine absorption; give oral atropine at least 1 hour prior to oral antacids
- **CORTICOSTEROIDS (long-term use):** may increase intraocular pressure

- **DIGOXIN (slow-dissolving):** Atropine may increase serum digoxin levels; use regular digoxin tablets or oral liquid
- **KETOCONAZOLE:** Increased gastric pH may decrease GI absorption; administer atropine 2 hours after ketoconazole
- **METOCLOPRAMIDE:** Atropine and its derivatives may antagonize the actions of metoclopramide

Doses

■ DOGS:

As an adjunct to anesthesia:

- a) 0.011 mg/kg IV, IM, or SC (Package Insert; Robinul®-V—Fort Dodge)
- b) 0.01–0.02 mg/kg SC or IM (Bellah 1988)

For adjunctive therapy of bradyarrhythmias:

- a) 0.011 mg/kg IV or IM (Russell and Rush 1995)
- b) Associated with anesthesia: 0.005–0.01 mg/kg IV (Pablo 2003a)

To reduce hypersialism:

- a) 0.01 mg/kg SC as needed (Krahwinkel 1988)

■ CATS:

As an adjunct to anesthesia:

- a) 0.011 mg/kg IM, for maximum effect give 15 minutes prior to anesthetic administration (Package Insert; Robinul®-V—Fort Dodge)

For bradyarrhythmias:

- a) 0.005–0.01 mg/kg IV or IM, 0.01–0.02 mg/kg SC (Tilley and Miller 1986)
- b) Associated with anesthesia: 0.005–0.01 mg/kg IV (Pablo 2003a)

■ FERRETS:

As a premed:

- a) 0.01 mg/kg SC or IM (Williams 2000)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: For prevention of bradycardia and to decrease airway and salivary secretions: 0.01–0.1 mg/kg IM, SC; 0.01 mg/kg IV (Ivey and Morrissey 2000)
- b) Rabbits: As adjunct to anesthesia: 0.01–0.02 mg/kg SC as needed (Huerkamp 1995)

■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

For treatment of bradyarrhythmias:

- a) 0.005–0.01 (5–10 mcg/kg) mg/kg IV (Mogg 1999)

As a bronchodilator:

- a) Initially, 2–3 mg IM two to three times daily for a 450 kg animal (Beech 1987)

To control muscarinic adverse effects associated with imidocarb therapy:

- a) 0.0025 mg/kg IV (Donnellan, Page et al. 2003)

Monitoring

- Dependent on route of administration, dose, and reason for use. See the atropine monograph for more information.

Client Information

- Parenteral glycopyrrolate administration is best performed by professional staff and where adequate cardiac monitoring is available.
- If animal is receiving glycopyrrolate tablets, allow animal free access to water and encourage drinking if dry mouth is a problem.

Chemistry/Synonyms

A synthetic quaternary ammonium antimuscarinic agent, glycopyrrolate occurs as a bitter-tasting, practically odorless, white, crystalline powder with a melting range of 193–198°C. One gram is soluble in 20 mL of water; 30 mL of alcohol. The commercially available injection is adjusted to a pH of 2–3 and contains 0.9% benzyl alcohol as a preservative.

Glycopyrrolate may also be known as: glycopyrronium bromide, AHR-504, *Acpan*®, *AmTech*®, *Gastrodyn*®, *Glycostigmin*®, and *Robinul*®.

Storage/Stability/Compatibility

Glycopyrrolate tablets should be stored in tight containers and both the injection and tablets should be stored at room temperature (15–30°C).

Glycopyrrolate is stable under ordinary conditions of light and temperature. It is most stable in solution at an acidic pH and undergoes ester hydrolysis at pH's above 6.

Glycopyrrolate injection is physically **stable** in the following IV solutions: D5W, D5/half normal saline, Ringer's injection, and normal saline. Glycopyrrolate may be administered via the tubing of an IV running lactated Ringer's, but rapid hydrolysis will occur if it is added to an IV bag of LRS. The following drugs are reportedly physically **compatible** with glycopyrrolate: atropine sulfate, benzquinamide, chlorpromazine HCl, codeine phosphate, diphenhydramine HCl, droperidol, droperidol/fentanyl, hydromorphone, hydroxyzine HCl, lidocaine HCl, meperidine HCl, meperidine HCl/promethazine HCl, morphine sulfate, neostigmine methylsulfate, oxymorphone HCl, procaine HCl, prochlorperazine HCl, promazine HCl, promethazine HCl, pyridostigmine Br, scopolamine HBr, and trimethobenzamide HCl.

The following drugs are reportedly physically **incompatible** with glycopyrrolate: chloramphenicol sodium succinate, dexamethasone sodium phosphate, diazepam, dimenhydrinate, methohexital sodium, methylprednisolone sodium succinate, pentazocine lactate, pentobarbital sodium, secobarbital sodium, sodium bicarbonate, and thiopental sodium. Other alkaline drugs (e.g., thiamylal) would also be expected to be **incompatible** with glycopyrrolate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Glycopyrrolate for Injection: 0.2 mg/mL in 20 mL vials; *Robinul*®-V (Fort Dodge), *AmTech*® *Glycopyrrolate Injectable* (IVX); (Rx). Approved for use in dogs and cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Glycopyrrolate Tablets: 1 mg and 2 mg; *Robinul*® and *Robinul Forte*® (Horizon); generic (Rising); (Rx)

Glycopyrrolate for Injection: 0.2 mg/mL in 1 mL, 2 mL, 5 mL, and 20 mL vials; *Robinul*® (Robins); generic; (Rx)

**GOLD SALTS, INJECTABLE
GOLD SODIUM THIOMALATE**

(*gold soe-dee-um thye-oh-mal-ate*) Aurothiomalate, Aurolate®, Myochrisine®

AUROTHIOGLUCOSE

(*aur-oh-thye-oh-gloo-kose*) Solganal®

INJECTABLE GOLD IMMUNOSUPPRESSIVES**Prescriber Highlights**

- Aurothioglucoese may no longer be available commercially; potentially may substitute with gold sodium thiomalate (aurothiomalate)
- Injectable administered gold; for pemphigus complex in small animals or plasmacytic stomatitis/pyodermitis in cats; may also be useful for pemphigus in goats or horses
- Can be quite toxic & expensive, intensive ongoing monitoring required
- Considered contraindicated in SLE (exacerbates), renal or hepatic disease, preexisting hematologic abnormalities, severe debilitation, or uncontrolled diabetes
- Possible teratogen
- Litany of serious adverse effects possible; pain on injection

Note: Aurothioglucoese has traditionally been the injectable gold compound used in veterinary medicine, but it may no longer be commercially available. Some now use gold sodium thiomalate (aurothiomalate) in its place. The following monograph primarily applies to aurothioglucoese, but the two drugs are thought to have similar actions, adverse effects, etc. Doses specific for gold sodium thiomalate are noted in the dosage section.

Uses/Indications

In human medicine, gold compounds are used primarily as a treatment for rheumatoid arthritis that has not adequately responded to less toxic treatment modalities. In veterinary medicine (primarily small animal medicine), its use has been generally for treating immune-mediated serious skin disorders such as pemphigus complex in dogs or cats and plasmacytic stomatitis/pyodermitis in cats. Gold salts have also been used to treat goats and horses with pemphigus.

Pharmacology/Actions

Injectable gold compounds have antiinflammatory, antirheumatic, immunomodulating, and antimicrobial (*in vitro*) effects. The exact mechanisms for these actions are not well understood. Gold is taken up by macrophages where it inhibits phagocytosis and may inhibit lysosomal enzyme activity. Gold also inhibits the release of histamine, and production of prostaglandins. While gold does have antimicrobial effects *in vitro*, it is not clinically useful for this purpose.

Pharmacokinetics

After IM injection, aurothioglucose is quite rapidly absorbed and peak serum concentrations are reached in 4–6 hours. It is distributed to several tissues (liver, kidney, spleen, bone marrow, adrenals, and lymph nodes), but highest levels are found in the synovium. In plasma, 95% is bound to plasma proteins. Gold salts may be found in the epithelial cells in the renal tubules years after dosing has ended. Plasma half-lives increase in length after multiple doses have been given. These values have ranged from 21–168 hours in humans. Approximately 70% of a dose is excreted by the kidneys, while the remaining 30% is excreted in the feces.

There appears to be no correlation with serum levels and efficacy. It usually takes from 6–12 weeks for a beneficial effect to be noted after beginning therapy.

Contraindications/Precautions/Warnings

Contraindications for chrysotherapy (gold therapy) include patients with renal or hepatic disease, SLE (lupus erythematosus, diabetes mellitus (uncontrolled), severe debilitation, and preexisting hematologic disorders.

Do not administer these compounds intravenously.

Adverse Effects

Veterinary experience with these agents is limited. Pain at the injection site is common and some animals may develop thrombocytopenia with petechia and ecchymoses. One author (Kummel 1995), reports that four pemphigus canine cases treated with aurothioglucose given immediately after cessation of azathioprine, developed a fatal toxic epidermal necrolysis. Other adverse effects noted in cats or dogs include stomatitis, hepatic necrosis or renal dysfunction.

Adverse reactions seen in people include: mucocutaneous reactions, which are fairly common (15–20%) and are characterized by rashes, (with or preceded by pruritus), and mucosal lesions (usually seen as a stomatitis). Hematologic reactions (thrombocytopenia, leukopenia, aplastic anemias), although rare in humans, can be life threatening. Renal effects are generally mild and if noted early, reversible with cessation of therapy. Proteinuria is an early sign associated with the proximal tubule damage that gold can cause. Reversible pulmonary infiltrates have been noted, but are reversible when therapy is discontinued. Enterocolitis, which may be fatal, has been reported in rare instances.

Because of the serious nature of these adverse reactions, adequate patient monitoring is essential.

Reproductive/Nursing Safety

The safety of aurothioglucose or gold sodium thiomalate has not been established during pregnancy, and these drugs should only be used when the potential benefits outweigh the risks involved. In humans, the FDA categorizes them as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Injectable gold is excreted in milk. Trace amounts appear in the serum and red blood cells of nursing offspring. As this may cause adverse effects in nursing offspring, switching to milk replacer is recommended if gold therapy is to be continued in the dam. Because gold is slowly excreted, persistence in milk will occur even after the drug is discontinued.

Overdosage/Acute Toxicity

Overdosages resulting from a too rapid increase in dosage are exhibited by rapid development of toxic signs, primarily renal (hematuria, proteinuria) and hematologic (thrombocytopenia, granulocytopenia) effects. Other clinical signs include: nausea, vomiting, diarrhea, skin lesions, and fever.

Treat with dimercaprol (BAL) to chelate the gold and treat the hematologic and renal effects supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving injectable gold compounds and may be of significance in veterinary patients:

- **CYTOTOXIC AGENTS** (including **high dose corticosteroids**): Auranofin's safety when used with these agents has not been established; use with caution
- **PENICILLAMINE** or **ANTIMALARIAL DRUGS**: Use with gold salts is not recommended due to the increased potential for hematologic or renal toxicity

Doses

Note: Dosages below are for the product aurothioglucose, unless otherwise noted; however, dosing for both drugs appear to be equivalent.

■ DOGS:

For canine pemphigus foliaceus/vulgaris:

- a) Gold sodium thiomalate: 1–5 mg IM as a test dose then 1 mg/kg IM once weekly. Need to use initially with glucocorticoids as gold therapy may take 6–8 weeks to take effect. Side effects include skin lesions, thrombocytopenia and toxic epidermal necrolysis. (Logas 2005a)
- b) Gold sodium thiomalate: 1–5 mg (1 mg for small patients; 5 mg for large patients) IM as a test dose then 1 mg/kg IM once weekly until remission, then taper to monthly. (Morris 2004)
- c) For those cases where corticosteroids and/or azathioprine are ineffective or causing unacceptable adverse effects: Discontinue azathioprine for one month and then give 1 mg/5kg of body weight IM weekly for 10 weeks and then monthly thereafter. **Note:** Before treating, the reader is advised to refer to the full reference for additional information. (Kummel 1995)
- d) 1 mg/kg IM (the paraspinal muscles work best) weekly for 6–12 weeks; then decrease to every other week and if possible, once monthly. Rarely, may be able to discontinue injections if free from clinical signs for 6 months after switching to once monthly injections. Corticosteroids must usually be used with gold therapy. (White 2000)

■ CATS:

- a) For pemphigus complex or plasmacytic/pododermatitis: Gold sodium thiomalate: 1–5 mg IM as a test dose then 1 mg/kg IM once weekly. Need to use initially with glucocorticoids as gold therapy may take 6–8 weeks to take effect. Side effects include skin lesions, thrombocytopenia and toxic epidermal necrolysis. (Logas 2005a)
- b) For pemphigus complex (rescue drug) or plasmacytic/pododermatitis: Gold sodium thiomalate: 1–5 mg (1 mg for small patients; 5 mg for large patients) IM as a test dose then 1 mg/kg IM once weekly until remission, then taper to monthly. (Morris 2004)
- c) Give animal test dose of 1 mg IM the first week and 2 mg the second week. If no adverse reactions seen (see adverse effects), give 1 mg/kg IM once weekly until either clinical im-

provement, toxic reactions occur, or weekly dosing has gone on for 20 weeks. Once remission is achieved, attempt to reduce dose and/or increase dosing interval to denote animals that have gone into remission. (Long 1986)

- d) Test dose of 1–5 mg IM, then 1 mg/kg IM weekly until remission, then monthly (Morgan 1988)
- e) First week 1 mg IM, 2nd week 2 mg IM; then 1 mg/kg once weekly IM decreasing to once per month (Kirk 1986)
- f) 1 mg/kg IM per week. Clinical response may take 6–8 weeks and combination with glucocorticoids is recommended. May be associated with renal dysfunction, drug eruptions, hepatic necrosis and thrombocytopenia. (Shaw 2003)
- g) For idiopathic pruritus when nothing else works: 1 mg/kg IM every 7 days until remission (8–20 weeks), then 1 mg/kg IM every 4 weeks (Hnilica 2003c)

■ HORSES:

- a) 1 mg/kg IM once a week decreasing to once a month (Schultz 1986)
- b) Give 20 mg IM and then 40 mg IM one week apart. If no adverse effects (stomatitis, urticaria, sloughing, blood dyscrasias), give 1 mg/kg IM weekly until observing a response (6–12 weeks). Tailor maintenance therapy to the individual, which may involve biweekly or monthly therapy. Treatment can be very expensive. Perform weekly CBC/urinalysis for the first month, then monthly if no abnormalities. (Rees 2004)

Monitoring

- Urinalysis—baseline, then weekly
- CBC—baseline, then every 2 weeks; **Note:** eosinophilia may denote impending reactions
- Renal and hepatic function tests; baseline and periodic. After the patient is on maintenance therapy, hemograms and urinalyses may be done every month or two.

Client Information

- Clients should be instructed to notify the veterinarian if pruritus, rash, or diarrhea develops, or if the animal becomes ill or depressed

Chemistry/Synonyms

A water-soluble gold salt, aurothioglucose contains approximately 50% gold. It is practically insoluble in alcohol and insoluble in vegetable oils. The commercial product is a 5% (50 mg/mL) suspension in sesame oil, 2% aluminum monostearate, and propylparaben is added as a preservative.

Gold sodium thiomalate occurs as an odorless, or practically odorless, yellow powder containing approximately 50% gold. It is very soluble in water. The injection is a light yellow to yellow solution with a pH of 5.8–6.5 and contains benzyl alcohol as a preservative.

Aurothioglucose may also be known as: 1-aurothio-D-glucopyranose, (D-glucosylthio)gold, gold thioglucose, *Aureotan*®, *Auromyose*®, *Gold-50*® and *Solganal*®.

Gold sodium thiomalate may also be known as aurothiomalate, *Aurolate*®, and *Myochrisine*®.

Storage/Stability/Compatibility

Protect these products from light and store between 15–30° C; avoid freezing. A five-year expiration date is assigned after manufacture. Do not mix with any other compound when injecting.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Gold Sodium Thiomalate Injection: 50 mg/mL in 2 mL and 10 mL vials; *Aurolate*® (Pasadena), *Myochrisine*® (Taylor), generic (Parenta); (Rx)

Aurothioglucose Injection Suspension: 50 mg/mL in 10 mL vials & multidose vials; Aurothioglucose (Parenta); *Solganal*® (Schering); (Rx) **Note:** While the above products are still listed as being available in some current human drug references, they may be discontinued.

GONADORELIN

(*goe-nad-oe-rell-in*) Cystorelin®, Fertagyl®, Factrel®

HORMONAL AGENT

Prescriber Highlights

- Hypothalamic hormone used to treat ovarian cysts & other reproductive disorders in a variety of species
- Contraindications & adverse effects: None reported
- No slaughter or milk withdrawal when used as labeled

Uses/Indications

Gonadorelin is indicated (approved) for the treatment of ovarian follicular cysts in dairy cattle. Additionally, gonadorelin has been used in cattle to reduce the time interval from calving to first ovulation and to increase the number of ovulations within the first 3 months after calving. This may be particularly important in increasing fertility in cows with retained placenta.

In dogs, gonadorelin has been used experimentally to help diagnose reproductive disorders or to identify intact animals versus castrated ones by maximally stimulating FSH and LH production. It has also been used experimentally in dogs to induce estrus through pulsatile dosing. While apparently effective, specialized administration equipment is required for this method.

Gonadorelin has been used in cats as an alternate therapy to FSH or hCG to induce estrus in cats with prolonged anestrus.

In Europe, a synthetic analogue buserelin has been used in horses to stimulate cyclic estrus. Its efficacy rates poorly when compared to an artificial light program, however.

In human medicine, gonadorelin has been used for the diagnosis of hypothalamic-pituitary dysfunction, cryptorchidism, and depression secondary to prolonged severe stress.

Pharmacology/Actions

Gonadorelin stimulates the production and the release of FSH and LH from the anterior pituitary. Secretion of endogenous GnRH from the hypothalamus is thought to be controlled by several factors, including circulating sex hormones.

Gonadorelin causes a surge-like release of FSH and LH after a single injection. In cows and ewes, this can induce ovulation, but not in estrus mares. A constant infusion of gonadorelin will initially stimulate LH and FSH release, but after a period of time, levels will return to baseline.

Pharmacokinetics

After intravenous injection in pigs, gonadorelin is rapidly distributed to extracellular fluid, with a distribution half-life of about 2 minutes. The elimination half-life of gonadorelin is approximately 13 minutes in the pig.

After intravenous injection in humans, gonadorelin reportedly has a plasma half-life of only a few minutes. Within one hour, approximately half the dose is excreted in the urine as metabolites.

Contraindications/Precautions/Warnings

None are noted on the label.

Adverse Effects

No reported adverse reactions were located for this agent. Synthetically prepared gonadorelin should not cause any hypersensitivity reactions. This may not be the case with pituitary-obtained LH preparations or hCG.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

No specific lactation safety information was listed for this drug.

Overdosage/Acute Toxicity

In doses of up to 120 micrograms/kg, no untoward effects were noted in several species of test animals. Gonadorelin is unlikely to cause significant adverse effects after inadvertent overdosage.

Drug Interactions

None were noted.

Doses

■ DOGS:

- GnRH challenge to test pituitary sufficiency or testicular steroidogenesis: 125–250 ng/kg (refer to reference for more information) (Amann 1986)
- To aid in the descent of cryptorchid testes: 50–100 micrograms SC or IV; if no response give additional dose in 4–6 days (Cox 1986)
- To increase libido in male dogs: Anecdotally, 50–100 mcg IM weekly for 4 to 6 weeks may improve libido. (Freshman 2002c)
- For cystic ovarian disease in bitches: 3.3 mcg/kg IM once daily for 3 days. An elevated progesterone level (>2 ng/mL) measured 1–2 weeks post treatment verifies success. (Purswell 1999)

■ CATS:

- To stimulate ovulation after mating: 25 micrograms IM after mating (Morgan 1988)
- For infertility, reduced libido, testis descent in male cats: 1 mcg/kg every 2–3 days (Verstegen 2000)
- To detect ovarian remnants in queens after ovariohysterectomy: 25 mcg per cat. A progesterone level (>1 ng/mL) measured 1–2 weeks post treatment verifies presence of ovarian tissue in the abdomen. (Purswell 1999)

■ FERRETS:

- 20 mcg IM; repeat in one week as necessary. Most effective 14 days after onset of estrus (Williams 2000)

■ CATTLE:

To treat of ovarian cysts in cattle:

- 100 micrograms IM or IV (Package Insert; *Cystorelin*®—Ceva)
- 100 micrograms IM per cow (Package insert; *Factrel*®—Fort Dodge)

■ SHEEP & GOATS:

- To induce ovulation outside of the breeding season in the doe: 100 micrograms injected daily for 4–5 days (Smith 1986b)

Chemistry/Synonyms

A hormone produced by the hypothalamus, gonadorelin is obtained from natural sources or is synthetically produced. It is a decapeptide that occurs as white or faintly yellowish-white powder. One gram is soluble in 25 mL of water or in 50 mL of methyl alcohol. 50 mcg of gonadorelin acetate is approximately equivalent to 31 units. The commercially available products in the United States are the diacetate decahydrate (*Cystorelin*®, others) and HCl (*Factrel*®) salts.

Gonadorelin may also be known as: follicle stimulating hormone-releasing factor, GnRH, gonadoliberin, gonadorelinum, gonadotrophin-releasing hormone, Hoe-471, LH/FSH-RF, LH/FSH-RH, LH-RF, LH-RH, luliberin, luteinising hormone-releasing factor, *Cryptocur*®, *Cystorelin*®, *Factrel*®, *Fertagyl*®, *Fertiral*®, *HRF*®, *Kryptocur*®, *LRH*®, *Luforan*®, *Luteoliberina*®, *Lutrefact*®, *Ovacyst*®, *Parlib*®, *Pulsti*®, *Relefact LH-RH*®, and *Stimu-LH*®.

Storage/Stability/Compatibility

The manufacturers recommend storing gonadorelin in the refrigerator (2–8°C). There is very little information available on the stability and compatibility of gonadorelin. Because bacterial contamination can inactivate the product, it has been recommended that multi-dose vials be used completely and as rapidly as possible.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Gonadorelin (diacetate tetrahydrate) for Injection: 50 micrograms/mL, 2 mL single-use or 10 mL multi-dose vials; *Cystorelin*® (Merial); *Fertagyl*® (Intervet); *Ovacyst*®, (RXV); (Rx). Approved for use in dairy cattle. There are no withdrawal times required for either milk or slaughter.

Gonadorelin HCl Solution for Injection: 50 mcg/mL in 2 mL single-use, and 20 mL multi-dose vials; *Factrel*® (Fort Dodge); (Rx). Approved for use in cattle. No withdrawal period required.

HUMAN-LABELED PRODUCTS:

Gonadorelin HCl Powder for Injection (lyophilized): 100 mcg/vial, 500 mcg/vial (as hydrochloride) with 2 mL sterile diluent; *Factrel*® (Wyeth-Ayerst); (Rx)

Gonadotropin, Chorionic — See Chorionic Gonadotropin

GRANISETRON HCL

(gran-iss-eh-tron) Kytril®

5-HT₃ ANTAGONIST ANTIEMETIC**Prescriber Highlights**

- ▶ 5-HT₃ receptor antagonist for the treatment of severe vomiting or emesis prophylaxis before chemotherapy
- ▶ Appears to be safe
- ▶ Relatively expensive

Uses/Indications

Granisetron is an alternative to other 5-HT₃ receptor antagonists (e.g., ondansetron or dolasetron) for the treatment of severe vomiting or prophylaxis before administering antineoplastic drugs such as cisplatin that can cause severe vomiting.

Pharmacology/Actions

Granisetron, like ondansetron or dolasetron, exerts its anti-nausea and antiemetic actions by selectively antagonizing 5-hydroxytryptamine₃ (5-HT₃; serotonin₃) receptors. These receptors are found primarily in the CNS chemoreceptor trigger zone, on vagal nerve terminals and enteric neurons in the GI tract. Chemotherapy associated vomiting in cats is believed primarily due to activation of 5-HT₃ receptors in the chemoreceptor trigger zone (CTZ), but in dogs, enteric and vagal receptors may be more important.

Pharmacokinetics

No pharmacokinetic data for dogs or cats was located. In humans, granisetron is rapidly absorbed after oral dosing and peak levels occur in about 2 hours. Oral bioavailability is only 60% due to first-pass metabolism in the liver. The presence of food can decrease AUC by 5%, but increase peak levels by 30%. Granisetron has a volume of distribution of about 3 L/kg and plasma protein binding is approximately 65%. The drug is metabolized in the liver, primarily via demethylation and oxidation and then conjugation. Less than 20% is excreted unchanged in the urine; the remainder is eliminated in the urine and feces as metabolites. Elimination half-life varies considerably, with reported values from about 1–30 hours. Cancer patients appear to have longer elimination half-lives than do healthy adults.

Contraindications/Precautions/Warnings

There are no known contraindications to using this medication in dogs or cats. In humans, granisetron is contraindicated in patients hypersensitive to it and it should not be used to treat vomiting associated with apomorphine (see Drug Interactions).

No dosage adjustments are required in elderly patients or those with impaired renal or hepatic function. Granisetron may mask the signs associated with progressive ileus and/or gastric distention; it should not replace required nasogastric suction.

Adverse Effects

Because of limited use in dogs and cats, a comprehensive adverse effect profile for granisetron is not known, however, it appears to be tolerated well.

In humans, the most common adverse effect reported is headache. Other adverse effects that may occur include abdominal pain, constipation or diarrhea, asthenia, or somnolence. Rarely, hypersensitivity reactions or cardiovascular effects (arrhythmias, chest pain, hypotension) have been reported.

Reproductive/Nursing Safety

Safety in pregnancy is not clearly established, but high dose studies in rodents and rabbits did not demonstrate overt fetal toxicity or teratogenicity. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known if granisetron enters milk, but it is probably safe to use during nursing.

Overdosage/Acute Toxicity

Limited information is available. An overdose of 38.5 mg in a person caused only a slight headache. Observation and, if required, supportive treatment are suggested.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving granisetron and may be of significance in veterinary patients:

- **APOMORPHINE**: Profound hypotension can occur
- **KETOCONAZOLE**: May inhibit the metabolism of granisetron
- **PHENOBARBITAL**: Can induce the metabolism of granisetron

Laboratory Considerations

No specific laboratory concerns associated with granisetron

Doses■ **DOGS/CATS:**

- a) Cats (with pancreatitis): 0.1–0.5 mg/kg PO or IV q12–24h. (Zoran 2006c), (Washabau 2006b)
- b) Dogs or Cats: 0.1–0.5 mg/kg PO or IV twice daily. (Washabau 2006a)

Monitoring

- Clinical efficacy

Client Information

- This drug is usually used on an inpatient basis or during outpatient visits for chemotherapy
- If used orally on an outpatient basis, have client contact veterinarian for further instructions if vomiting is not controlled or if the dose is vomited up after administering

Chemistry/Synonyms

Granisetron HCl occurs as a white or almost white powder that is freely soluble in water. Dosages are expressed in terms of the base; 1.12 mg of granisetron HCl is equivalent to 1 mg of granisetron base.

Granisetron may also be known as: granistrone, granisetrono, or BRL-43694A, *Aludal*®, *Eumetic*®, *Granicip*®, *Granitron*, *Kytril*®, *Kevatril*®, *Rigmoz*® or *Setron*®.

Storage/Stability/Compatibility

The commercially available tablets and oral solution should be stored at room temperature (15–30°C) in tight containers and protected from light. The oral solution should be stored in an up-right position. The injectable solution should be stored between 15–30°C; preferably at 25°C. Protect from light and do not freeze solution. Once the multi-dose vial is penetrated, it must be used within 30 days.

The injectable solution is **compatible** with sodium chloride 0.9%, dextrose 5% in sodium chloride 0.45% or 0.9%, and dextrose 5% in water. It is compatible with many drugs at intravenous Y-sites, but is **incompatible** with amphotericin B.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Granisetron Oral Tablets: 1 mg (1.12 mg as HCl); *Kytril*® (Roche); (Rx)

Granisetron Oral Solution: 0.2 mg/mL (0.56 mg/mL as HCl, orange flavor; contains sorbitol) in 30 mL bottles; *Kytril*® (Roche); (Rx)

Granisetron Injection: 1 mg/mL (1.12 mg/mL as HCl) in 1 mL single-dose and 4 mL multi-dose vials; *Kytril*® (Roche); (Rx)

GRISEOFULVIN (MICROSIZED) GRISEOFULVIN (ULTRAMICROSIZED)

(gri-see-oh-ful-vin) Fulvicin®

ANTIFUNGAL AGENT

Prescriber Highlights

- ▶ Fungistatic antibiotic used primarily for ringworm & other dermatophytic infections; no effect on other fungi
- ▶ Contraindications: Pregnancy, known hypersensitivity, or hepatocellular failure
- ▶ Caution: Kittens may be overly sensitive to the drug; cats with FIV
- ▶ Adverse Effects: Anorexia, vomiting, diarrhea, anemia, neutropenia, leukopenia, thrombocytopenia, depression, ataxia, hepatotoxicity, or dermatitis/photosensitivity
- ▶ Known teratogen in cats
- ▶ Only new hair & nail growth resistant to fungi after treating
- ▶ Dosing is different for microsize & ultramicrosize forms

Uses/Indications

In veterinary species, griseofulvin is approved for use in dogs and cats to treat dermatophytic fungal (see below) infections of the skin, hair and claws, and to treat ringworm (caused by *T. equinum* and *M. gypseum*) in horses. It has also been used in laboratory animals and ruminants for the same indications. The oral tablets approved for dogs and cats are no longer marketed in the USA, but human dosage forms are available.

Pharmacology/Actions

Griseofulvin acts on susceptible fungi by disrupting the structure of the cell's mitotic spindle, arresting the metaphase of cell division. Griseofulvin has activity against species of *Trichophyton*, *Microsporum* and *Epidermophyton*. Only new hair and nail growth is resistant to infection. It has no antibacterial activity and is not clinically useful against other pathogenic fungi, including *Malessezia* yeasts.

Pharmacokinetics

The microsized form of the drug is absorbed variably (25–70%); dietary fat will enhance absorption. The ultramicrosize form of the drug may be nearly 100% absorbed. Generally, the ultramicrosize form is absorbed 1.5 times as well as the microsized form for a given patient.

Griseofulvin is concentrated in skin, hair, nails, fat, skeletal muscle, and the liver, and can be found in the stratum corneum within 4 hours of dosing.

Griseofulvin is metabolized by the liver via oxidative demethylation and glucuronidation to 6-desmethylgriseofulvin, which is not active. In humans, the half-life is 9–24 hours. A serum half-life of 47 minutes has been reported for dogs. Less than 1% of the drug is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

Griseofulvin is contraindicated in patients hypersensitive to it or with hepatocellular failure. It should not be used in pregnant animals.

Because kittens may be overly sensitive to the adverse effects associated with griseofulvin, they should be monitored carefully if treatment is instituted. Cats should be tested for FIV before using griseofulvin because of the possible neutropenic or panleukopenic effects of the drug.

Adverse Effects

Griseofulvin can cause anorexia, vomiting, diarrhea, anemia, neutropenia, leukopenia, thrombocytopenia, depression, ataxia, hepatotoxicity, dermatitis/photosensitivity and toxic epidermal necrolysis. With the exception of GI clinical signs, adverse effects are uncommon at usual doses. Cats, particularly kittens, may be more susceptible to adverse effects (e.g., bone marrow depression) than other species. This could be due to this species' propensity to more slowly form glucuronide conjugates and thus metabolize the drug at a slower rate than either dogs or humans.

Reproductive/Nursing Safety

Griseofulvin is a known teratogen in cats and, probably, in dogs as well. Dosages of 35 mg/kg given to cats during the first trimester caused cleft palate and other skeletal and brain malformations in kittens. Griseofulvin may also inhibit spermatogenesis. Because dermatophytic infections are not generally life-threatening and alternative therapies are available, use of the drug should be considered contraindicated during pregnancy. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **D** (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

No lactation safety information was found.

Overdosage/Acute Toxicity

No specifics regarding griseofulvin overdosage or acute toxicity were located. It is suggested that significant overdoses be handled with gut emptying, charcoal and cathartic administration unless contraindicated. Contact a poison control center for more information.

Horses have received 100 mg/kg PO for 20 days without apparent ill effect.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving griseofulvin and may be of significance in veterinary patients:

- **ALCOHOL:** Griseofulvin may potentiate the effects of alcohol
- **ASPIRIN:** Griseofulvin may decrease salicylate levels
- **CYCLOSPORINE:** Griseofulvin may decrease cyclosporine levels
- **PHENOBARBITAL:** Phenobarbital and other barbiturates have been implicated in causing decreased griseofulvin blood concentrations, presumably by inducing hepatic microsomal enzymes and/or reducing absorption. If phenobarbital and griseofulvin are given concurrently, griseofulvin dosage adjustment may be necessary.
- **THEOPHYLLINE:** In some patients, griseofulvin may decrease theophylline half-life and levels
- **WARFARIN:** Coumarin anticoagulants may have their anticoagulant activity reduced by griseofulvin; anticoagulant adjustment may be required

Doses

Note: all doses are for microsize preparations unless otherwise indicated.

■ DOGS:

For susceptible dermatophytic infections:

- a) Microsize: 25 mg/kg q12h PO for 42–56 days; Ultramicrosize: 5–10 mg/kg PO once daily for 42 days. May need to treat longer for *Trichophyton* than for *Microsporum*. Give following a fatty meal or administration of corn oil. Continue for at least 2 weeks after resolution of signs and at least 5 months for onychomycosis. (Greene, Hartmann et al. 2006)
- b) Microsize: 50 mg/kg PO once daily with fatty meal. Used with topical therapy (see references). May double dose in resistant cases. If GI distress occurs may divide dose and give twice daily with food. Prolonged course of therapy required. Begin taking cultures after 4 weeks of treatment. Continue therapy for 2 weeks beyond clinical cure and when 2–3 negative cultures are obtained at weekly intervals. (Frank 2000)

■ CATS:

For susceptible dermatophytic infections:

- a) Microsize: 50–120 mg/kg PO; divided daily. Give with a fatty meal. Ultramicrosize: 10–15 mg/kg PO twice daily. Give for 4–6 weeks or longer, until culture is negative. (Foil 2003b)
- b) Microsize: 50 mg/kg PO once daily or 25 mg/kg PO q12h for 42–70 days; Ultramicrosize: 5–10 mg/kg PO once daily for 42 days. Give following a fatty meal or administration of corn oil. Continue for at least 2 weeks after resolution of signs and at least 5 months for onychomycosis. (Greene, Hartmann et al. 2006)
- c) For feline *M. canis*: After total body clip, griseofulvin 80–130 mg/kg PO once daily with a fatty meal or 2.5–5 mL of corn oil. Re-clip after one month and continue treatment until signs of infection have disappeared and cultures are negative. (Thoday 1986)
- d) Microsize: 50 mg/kg PO once daily with fatty meal. Used with topical therapy (see references). May double dose in resistant cases. If GI distress occurs may divide dose and give twice daily with food. Prolonged course of therapy required. Begin taking cultures after 4 weeks of treatment. Continue therapy for 2 weeks beyond clinical cure and when 2–3 negative cultures are obtained at weekly intervals. (Frank 2000)

- e) For feline eosinophilic granuloma complex: Microsize: 25 mg/kg PO twice daily with food. Give at least for one month to judge efficacy. (White 2003b)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits for advanced dermatophytosis: Ultramicrosize 6.25 mg/kg PO q12h for 4–6 weeks. Microsize: 25 mg/kg PO q12–24h for one month (Ivey and Morrissey 2000)
- b) Chinchillas: 25 mg/kg PO once daily for 30–60 days (Hayes 2000)
- c) Gerbils, Guinea pigs, Hamsters, Rats: 25 mg/kg PO q24h for 14–28 days; Mice: 25 mg/kg PO q24h for 14 days; Chinchillas: 25 mg/kg PO q24h for 28–40 days (Adamcak and Otten 2000)
- d) Guinea pigs for dermatophytosis: 25 mg/kg PO (as a suspension) once daily for 28 days. (Johnson 2006d)
- e) Chinchillas: 25 mg/kg PO once daily (q24h) for 30 days (Johnson 2006a)

■ CATTLE (and other ruminants):

For susceptible dermatophytic infections:

- a) Ultramicrosize: 10–20 mg/kg PO once daily for 1–2 weeks. 100 mg/kg PO given twice (or more) 1 week apart may also be effective. Not approved for use in food animals and can be very expensive. (Pier 1986)
- b) 20 mg/kg PO once daily for 6 weeks (Howard 1986)

■ HORSES:

For susceptible dermatophytic infections:

- a) 10 mg/kg PO once daily (Robinson 1987)
- b) 10 mg/kg PO (in feed) daily for 7 days (Brumbaugh 1987)

■ SWINE:

For susceptible dermatophytic infections:

- a) 20 mg/kg PO once daily for 6 weeks (Howard 1986)

■ BIRDS:

- a) Ratites: 35–50 mg/kg PO once daily (Jenson 1998)

Monitoring

- Clinical efficacy; culture
- Adverse effects
- CBC; before therapy and q1–3 weeks during therapy
- Liver enzymes (if indicated)

Client Information

- Clients should be instructed in procedures used to prevent reinfection (destruction of old bedding, disinfection, periodic reexaminations, hair clipping, etc.), and the importance of compliance with the dosage regimen.
- Should animal develop adverse effects other than mild GI disturbances, they should contact their veterinarian.

Chemistry/Synonyms

A fungistatic antibiotic produced by species of *Penicillium* (primarily *P. griseofulvum*), griseofulvin occurs as an odorless or nearly odorless, bitter tasting, white to creamy white powder. It is very slightly soluble in water and sparingly soluble in alcohol.

Two forms of the drug are available commercially. Microsize griseofulvin contains particles with a predominant size of 4 micrometers in diameter, while the ultramicrosize form particle size averages less than 1 micron in diameter.

Griseofulvin may also be known as: curling factor, griseofulvina, and griseofulvinum; many trade names are available.

Storage/Stability/Compatibility

Although griseofulvin is relatively thermostable, products should be stored at less than 40°C, preferably at 15–30°C. Griseofulvin suspension should be stored in tight, light-resistant containers. Microsize tablets and capsules should be stored in tight containers; the ultramicrosize tablets should be stored in well-closed containers.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Griseofulvin (Microsize) Powder: 2.5 g griseofulvin in 15 g sachets; *AmTech® Griseofulvin Powder* (IVX); (Rx). Approved for use in horses not intended for food.

HUMAN-LABELED PRODUCTS:

Griseofulvin Microsize Tablets: 500 mg; *Grifulvin V®* (Ortho); (Rx)

Griseofulvin Microsize Oral Suspension: 125 mL/5 mL in 120 mL; *Grifulvin V®* (Ortho); generic; (Rx)

Griseofulvin Ultramicrosize Tablets: 125 mg & 250 mg; *Gris-PEG®* (Pedinol); (Rx)

GUAIFENESIN

(gwy-e-fen-e-sin) GG, Guailaxin®

PARENTERAL MUSCLE RELAXANT/ORAL
EXPECTORANT

Prescriber Highlights

- ▶ An expectorant (oral) & muscle relaxant (parenteral) adjunctive to anesthesia
- ▶ Contraindications: None noted except concurrent use with physostigmine
- ▶ Adverse Effects: Mild hypotensive effect & increase in cardiac rate, thrombophlebitis possible

Uses/Indications

In veterinary medicine, guaifenesin is used to induce muscle relaxation and restraint as an adjunct to anesthesia for short procedures (30–60 minutes) in large and small animal species. There are combination oral products containing guaifenesin for treating respiratory conditions in horses.

In human medicine, guaifenesin has long been touted as an oral expectorant, but definitive proof of its efficacy is lacking.

Pharmacology/Actions

While the exact mechanism of action for the muscle relaxant effect is not known, it is believed that guaifenesin acts centrally by depressing or blocking nerve impulse transmission at the internuncial neuron level of the subcortical areas of the brain, brainstem and spinal cord. It relaxes both the laryngeal and pharyngeal muscles, thus allowing easier intubation. Guaifenesin also has mild intrinsic analgesic and sedative qualities.

Guaifenesin causes an excitement-free induction and recovery from anesthesia in horses. It produces relaxation of skeletal muscles but does not affect diaphragmatic function and has little, if any, effect on respiratory function at usual doses. Possible effects on the cardiovascular system include transient mild decreases in blood pressure and increases in cardiac rate. Gastrointestinal motility may be increased, but generally no adversity is seen with this.

Guaifenesin potentiates the activity of preanesthetic and anesthetic agents.

Pharmacokinetics

The pharmacokinetics of guaifenesin have not been thoroughly studied in most species. When administered alone to horses IV, recumbency usually occurs within 2 minutes and light (not surgical level) restraint persists for about 6 minutes. Muscle relaxation reportedly persists for 10–20 minutes after a single dose.

Guaifenesin is conjugated in the liver and excreted into the urine. A gender difference in the elimination half-life of guaifenesin in ponies has been demonstrated, with males having a $t_{1/2}$ of approximately 85 minutes, and females a $t_{1/2}$ of about 60 minutes. Guaifenesin reportedly crosses the placenta, but adverse effects in newborns of mothers who received guaifenesin have not been described.

Contraindications/Precautions/Warnings

The manufacturer states that the use of physostigmine is contraindicated with guaifenesin (see Drug Interactions).

Adverse Effects

At usual doses, side effects are transient and generally minor. A mild decrease in blood pressure and increase in cardiac rate can be seen. Thrombophlebitis has been reported after IV injection, and perivascular administration may cause some tissue reaction. Hemolysis may occur in solutions containing greater than a 5% concentration of guaifenesin, but some sources state this is insignificant at even a 15% concentration.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether guaifenesin is excreted in milk.

Overdosage/Acute Toxicity

The margin of safety is reportedly 3 times the usual dose. Clinical signs of apneustic breathing, nystagmus, hypotension, and contradictory muscle rigidity are associated with toxic levels of the drug.

There were 69 exposures to guaifenesin reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2000–2006. In these cases 59 were dogs with only 1 showing clinical signs and 8 cases were cats with only 1 showing clinical signs. The remaining 2 cases were birds which showed no clinical signs. The dog received a dosage estimated between 415 and 830 mg/kg and exhibited hypothermia, mild tremors, ataxia and vomiting. The cat received a dosage of 132 mg/kg and exhibited lethargy and anorexia.

No specific antidote is available. It is suggested that treatment be supportive until the drug is cleared to sub-toxic levels.

Drug Interactions

Drug interactions with guaifenesin are not well studied. The following drug interactions have either been reported or are theoretical in animals receiving guaifenesin and may be of significance in veterinary patients:

- **PHYSOSTIGMINE:** The manufacturer (Robins) states that physostigmine is contraindicated in horses receiving guaifenesin, but does not elucidate on the actual interaction. It may be logical to assume that other anticholinesterase agents (**neostigmine**, **pyridostigmine**, **edrophonium**) may also be contraindicated.

Doses**■ DOGS:**

- a) Guaifenesin only: 44–88 mg/kg IV; or guaifenesin 33–88 mg/kg IV with 2.2–6.6 mg/kg thiamylal or 1.1 mg/kg ketamine (Muir)
- b) 110 mg/kg IV for muscle relaxation during certain toxicoses (e.g., strychnine) or tetanus (Morgan 1988), (Bailey 1986a)
- c) For chemical restraint for ventilatory support: Combination of guaifenesin 50 mg/mL, ketamine 1 mg/mL, and xylazine 0.25 mg/mL; give 0.55 mL bolus initially followed by 2.2 mL/kg/hr thereafter (Pascoe 1986)

■ CATTLE:

- a) Guaifenesin only: 66–132 mg/kg IV; or guaifenesin 44–88 mg/kg IV with 2.2–6.6 mg/kg thiamylal or 0.66–1.1 mg/kg ketamine (Muir)
- b) 55–110 mg/kg IV (Mandsager 1988)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- a) 110 mg/kg IV, give first $\frac{1}{3}$ – $\frac{1}{2}$ of dose until horse falls gently, then give remainder unless respiratory or cardiovascular effects are observed (Package Insert; *Guaifexin*®—Robins)
- b) Guaifenesin only: 66–132 mg/kg IV; or guaifenesin 44–88 mg/kg IV with 2.2–6.6 mg/kg thiamylal (Muir)
- c) 55–110 mg/kg IV (Mandsager 1988)
- d) For anesthesia: 100 mg/kg IV combined with barbiturate in 5% dextrose. As an expectorant: 3 mg/kg PO (Robinson 1987)
- e) For field anesthesia: Sedate with xylazine (1 mg/kg IV; 2 mg/kg IM) given 5–10 minutes (longer for IM route) before induction of anesthesia with ketamine (2 mg/kg IV). Horse must be adequately sedated (head to the knees) before giving the ketamine (ketamine can cause muscle rigidity and seizures). If adequate sedation does not occur, either **1**) Redose xylazine: up to half the original dose; **2**) Add butorphanol (0.02–0.04 mg/kg IV). Butorphanol can be given with the original xylazine if you suspect that the horse will be difficult to tranquilize (e.g., high-strung Thoroughbreds) or added before the ketamine. This combination will improve induction, increase analgesia and increase recumbency time by about 5–10 minutes; **3**) Diazepam (0.03 mg/kg IV). Mix the diazepam with the ketamine. This combination will improve induction when sedation is marginal, improve muscle relaxation during anesthesia and prolong anesthesia by about 5–10 minutes; **4**) Guaifenesin (5% solution administered IV to effect) can also be used to increase sedation and muscle relaxation. (Mathews 1999)
- f) For adjunctive symptomatic treatment of strychnine poisoning: 110 mg/kg IV; repeated as necessary (Schmitz 2004)

■ SWINE:

- a) Guaifenesin only: 44–88 mg/kg IV; or guaifenesin 33–88 mg/kg IV with 2.2–6.6 mg/kg thiamylal or 1.1 mg/kg ketamine (Muir)

■ GOATS:

- a) Guaifenesin only: 66–132 mg/kg IV; or guaifenesin 44–88 mg/kg IV with 0.66–1.1 mg/kg ketamine (Muir)

Monitoring

- Level of muscle relaxation
- Cardiac and respiratory rate

Chemistry/Synonyms

Formerly known as glyceryl guaiacolate, guaifenesin occurs as a white to slightly gray, crystalline powder that may have a characteristic odor. It is nonhygroscopic and melts between 78°–82°C. One gram is soluble in 15 mL of water and soluble in alcohol, propylene glycol and glycerin.

Guaifenesin may also be known as: GG, glyceryl guaiacolate, glycerylguayacolum, guaiacol glycerol ether, guaiacyl glyceryl ether, guaifenesina, guaifenesinum, guaiphenesin, and guajacolum glycerolatum; many trade names are available.

Storage/Stability/Compatibility

Guaifenesin is stable in light and heat (less than melting point). It should be stored in well-closed containers.

When dissolved into aqueous solutions, guaifenesin may slightly precipitate out of solution when the temperature is less than 22°C (72°F). Slight warming and agitation generally resolubilizes the drug. A microwave oven has been suggested for heating and dissolving the drug. It is recommended that the solution be prepared freshly before use, but a 10% solution (in sterile water) may apparently be stored safely at room temperature for up to one week with only slight precipitation occurring.

Guaifenesin is physically **compatible** with sterile water or D5W. It is also reportedly **compatible** with ketamine, pentobarbital, thiamylal, thiopental, and xylazine.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Guaifenesin Injection 50 mg/mL in 1000 mL: *Guaifinject*® (Butler), generic, (IVX, RXV, Vedco, Phoenix Pharmaceutical); (Rx). Approved for use in horses not intended for food.

There are several oral products containing guaifenesin in combination with an antihistamine (pyrilamine) labeled for use in horses, including *Anhist*® (AHC), & *Hist-EQ*® Powder (Butler); (OTC)

There are oral products containing guaifenesin and other expectorants (potassium iodide, ammonium chloride) labeled for use in horses, cattle, and sheep, including *Spect-Aid*® (AHC), and *Spec-Tuss*® (Neogen); (OTC)

There may be veterinary oral cough syrups or tablets containing guaifenesin available labeled for use in small animals.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Guaifenesin (Glyceryl Guaiacolate) Tablets: 200 mg & 400 mg; 600 mg & 1200 mg (extended-release); *Organidin NR*® (Medpointe); *All-fen Jr*® (MCR American); *Liquibid*® (Capellon); (Rx); *Guaifenesin* (URL); *Mucinex*® (Adams); *Humibid Maximum* (Adams); generic; (OTC)

Guaifenesin Granules: 50 mg or 100 mg/packet; *Mucinex*® *Mini-Melts Children's & Junior Strength* (Adams Laboratories); (OTC)

Guaifenesin Syrup/Liquid: 100 mg/5mL in 118 mL, 237 mL & 473 mL; 200 mg/5 mL in 120 mL; *Altarussin*® (Altaire); *Mucinex Children's*® (Adams Laboratories); *Diabetic Tussin*® (Health Care Products); *Robitussin*® (Wyeth); *Siltussin DAS*® & *SA*® (Silarx); *Scot-Tussin Expectorant*® (Scot-Tussin); *Naldecon Senior EX*® (Sandoz); (OTC); *Ganidin NR*® (Cypress); *Guaifenesin NR*® (Silarx); *Organidin NR*® (Medpointe); (Rx)

No parenteral preparations are approved. There are many OTC oral expectorant/cough preparations on the market.

HALOTHANE

(ha-loe-thane) Fluothane®

GENERAL ANESTHETIC

Prescriber Highlights

- ▶ **Classic inhalant general anesthetic; still used but largely supplanted by newer agents**
- ▶ **Contraindications:** History or predilection towards malignant hyperthermia; significant hepatotoxicity after previous exposure
- ▶ **Caution in patients with hepatic function impairment, cardiac arrhythmias, increased CSF or head injury, myasthenia gravis, or pheochromocytoma**
- ▶ **Adverse Effects:** Dose related hypotension, malignant hyperthermia-stress syndrome, cardiac depression & dysrhythmias, hepatotoxicity
- ▶ **May be teratogenic; use with caution in pregnancy**
- ▶ **Drug interactions**

Uses/Indications

Halothane remains a useful general anesthetic in veterinary medicine due to its relative safety, potency, controllability, non-flammability, and comparatively low cost. However, its use has been largely supplanted by newer agents such as isoflurane and sevoflurane that have less cardiodepressant effects.

Pharmacology/Actions

While the precise mechanism that inhalant anesthetics exert their general anesthetic effect is not precisely known, they may interfere with functioning of nerve cells in the brain by acting at the lipid matrix of the membrane. Some key pharmacologic effects noted with halothane include: CNS depression, depression of body temperature regulating centers, increased cerebral blood flow, respiratory depression (pronounced in ruminants), hypotension, vasodilation, and myocardial depression.

Minimal Alveolar Concentration (MAC; %) in oxygen reported for halothane in various species: Dog = 0.76; Cat = 0.82; Horse = 0.88; Human = 0.76. Several factors may alter MAC (acid/base status, temperature, other CNS depressants on board, age, ongoing acute disease, etc.).

Pharmacokinetics

Halothane is rapidly absorbed through the lungs. About 12% of absorbed drug is metabolized by the liver to trifluoroacetic acid (only small amounts), chlorine, and bromine radicals that are excreted in the urine. The bulk of the absorbed drug is re-excreted by the lungs and eliminated with expired air. Halothane is distributed into milk.

Contraindications/Precautions/Warnings

Halothane is contraindicated in patients with a history or predilection towards malignant hyperthermia or significant hepatotoxicity after previous halothane exposure (see Adverse Effects below). It should be used with caution (benefits vs. risks) in patients with hepatic function impairment, cardiac arrhythmias, increased CSF or head injury, myasthenia gravis, or pheochromocytoma (cardiac arrhythmias due to catecholamines).

Adverse Effects

Hypotension may occur and is considered dose-related. A malignant hyperthermia-stress syndrome has been reported in pigs, horses, dogs, and cats. Halothane may cause cardiac depression and dysrhythmias. Halothane-induced hypotension may be treated by volume expansion and dobutamine. Lidocaine has been used to treat or prevent halothane-induced cardiac dysrhythmias. In humans, jaundice and a postanesthetic fatal liver necrosis have been reported rarely. The incidence of this effect in veterinary species is not known, however, halothane should be considered contraindicated for future use if unexplained fever, jaundice, or other clinical signs associated with hepatotoxicity occur.

Reproductive/Nursing Safety

Some animal studies have shown that halothane may be teratogenic; use only when benefits outweigh potential risks. In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: *C* (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving halothane and may be of significance in veterinary patients:

- **ACETAMINOPHEN:** Is not recommended for use for post-operative analgesia in patients that have received halothane anesthesia
- **ACEPROMAZINE:** Can decrease requirements of halothane by up to 40%
- **AMINOGLYCOSIDES:** Use with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur
- **LINCOSAMIDES:** Use with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur
- **NON-DEPOLARIZING NEUROMUSCULAR BLOCKING AGENTS:** Additive neuromuscular blockade may occur
- **SUCCINYLCHOLINE:** With inhalation anesthetics, may induce increased incidences of cardiac effects (bradycardia, arrhythmias, sinus arrest and apnea) and, in susceptible patients, malignant hyperthermia
- **SYMPATHOMIMETICS** (dopamine, epinephrine, norepinephrine, ephedrine, metaraminol, etc.): Because halothane sensitizes the myocardium to the effects of sympathomimetics, especially catecholamines, severe ventricular arrhythmias may result. If these drugs are needed, they should be used with caution and in significantly reduced dosages with intensive monitoring
- **D-TUBOCURARINE:** May cause significant hypotension if used with halothane

Laboratory Considerations

- Halothane may transiently increase values of **liver function tests**.

Doses

■ DOGS/CATS:

Note: Concentrations are dependent upon fresh gas flow rate; the lower the flow rate, the higher the concentration required.

- a) 3% (induction); 0.5–1.5% (maintenance) (Papich 1992)
- b) 0.5–3.5%, inhaled (Hubbell 1994)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: Using a non-rebreathing system: Induction: 2–4%, maintenance: 0.25–2% (Anderson 1994); (Adamcak and Otten 2000)

■ **BIRDS:**

- a) Using an anesthetic vaporizer, induction usually occurs in 2–4 minutes at a concentration of 2% for small birds and 2.5–3% for large birds. Maintenance can generally be maintained at concentrations of 0.5–1.5%. Recovery usually takes 3–5 minutes. Bradycardia, hypotension and hypothermia may occur, but rapidly resolve once halothane is discontinued. (Bennett 2002)

■ **HORSES:**

- a) For draft horses: Following induction, the largest ET tube that will comfortably fit (20–40 mm) should be placed and cuff inflated. In an oxygen-enriched semi-closed large animal circle system 4–5% of halothane is administered initially and is reduced as indicated by physical monitoring of neural reflexes and cardiopulmonary parameters. The goal should be the lowest concentration inhalant anesthetic that provides adequate surgical anesthesia and restraint. Most draft horses can be maintained on 2.5–3% halothane. (See reference for more information on monitoring and use.) (Geiser 1992)

Monitoring

- Respiratory and ventilatory status
- Cardiac rate/rhythm; blood pressure (particularly with “at risk” patients)
- Level of anesthesia

Chemistry/Synonyms

An inhalant general anesthetic agent, halothane occurs as a colorless, nonflammable, heavy liquid. It has a characteristic odor resembling chloroform and a sweet, burning taste. Halothane is slightly soluble in water and miscible with alcohol. At 20°C, halothane’s specific gravity is 1.872–1.877 and vapor pressure is 243 mmHg.

Halothane may also be known as: phthorothanum, *Fluothane*®, and *Ineltano*®.

Storage/Stability/Compatibility

Store halothane below 40°C in a tight, light-resistant container. Halothane stability is maintained by the addition of thymol and ammonia. The thymol does not vaporize so it may accumulate in the vaporizer causing a yellow discoloration. Do not use discolored solutions. Discolored vaporizer and wick may be cleaned with diethyl ether (all ether must be removed before reuse).

In the presence of moisture, halothane vapor can react with aluminum, brass, and lead (not copper). Rubber and some plastics are soluble in halothane leading to their rapid deterioration.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Halothane in 250 mL bottles; (Abbott); (Rx)

HCG – see Chorionic Gonadotropin

HEMOGLOBIN GLUTAMER-200 (BOVINE)

(hee-moe-gloe-bin gloo-ta-mer) Oxyglobin®

SEMI-SYNTHETIC HEMOGLOBIN REPLACER;
COLLOID

Prescriber Highlights

- Bovine source polymerized hemoglobin product for the treatment of anemias
- Contraindications: Advanced cardiac disease, renal impairment with oliguria or anuria
- Many potential adverse effects; most are not serious (see below)
- Potential drug-lab interactions

Uses/Indications

Oxyglobin® is indicated for the treatment of dogs with anemia, regardless of the cause of anemia (hemolysis, blood loss, or ineffective erythropoiesis). From a prognostic standpoint, the drug should be more valuable in dogs with regenerative anemias (versus nonregenerative anemias). It has also been used extra-label in other species as well, such as in foals for neonatal isoerythrolysis.

Its primary benefit is for the patient that is anemic and difficult to transfuse due to unavailability of blood, or when no suitable donors are identified on crossmatch. (Jandrey 2007)

Pharmacology/Actions

The bovine hemoglobin in the product is polymerized into larger molecules to increase safety, efficacy, and intravascular persistence, is shipped in a deoxygenated state and becomes oxygenated once circulated through the lungs. *Oxyglobin*® releases oxygen to tissue in a mechanism similar to endogenous hemoglobin; thereby increasing plasma and total hemoglobin concentrations, and systemic oxygen content. Because of its small size (in comparison to normal RBC’s), it may better deliver oxygen to cells supplied by severely constricted arteries.

Oxyglobin® also has colloidal properties similar to dextran 70 and hetastarch.

Pharmacokinetics

In dogs receiving 15 mL/kg: peak plasma hemoglobin concentrations increased approximately 2.5 g/dl; at 30 mL/kg, approximately 4 mg/dl. Duration of effect continues for at least 24 hours. The plasma half-life in dogs at present labeled dosages is approximately 18–43 hours and *Oxyglobin*® can be detected in plasma for 5–7 days after a single dose.

As with endogenous hemoglobin, *Oxyglobin*® is metabolized and eliminated by the reticuloendothelial system. Small amounts of unstabilized hemoglobin (<5%) may be excreted through the kidneys, causing discoloration (red) of the urine.

Contraindications/Precautions/Warnings

As safe use of *Oxyglobin*® has not been tested for the following conditions and plasma expanders are generally contraindicated in them, the product is labeled as contraindicated in dogs with advanced cardiac disease (*i.e.*, congestive heart failure) or otherwise severely impaired cardiac function or renal impairment with oliguria or anuria. The safety and efficacy of *Oxyglobin*® has not been evaluated in dogs with DIC, thrombocytopenia

with active bleeding, hemoglobinemia and hemoglobinuria, or autoagglutination.

Administration of any foreign protein has the potential to cause immunologic reactions. While low levels of IgG antibodies have been detected after multiple dosages, no anaphylactic reactions have been reported thus far. If an immediate hypersensitivity reaction occurs, infusion should be immediately discontinued and appropriate treatment administered. If a delayed type of hypersensitivity reaction occurs, immunosuppressant therapy is recommended.

Adverse Effects

The package insert lists the following frequency of adverse reactions that occurred in greater than 4% of dogs treated with *Oxyglobin*® (**Note:** first figure is % of dogs treated; in parentheses: % treated having hemolytic anemia): Discolored mucous membranes 69% (47%); discolored sclera (yellow, red, brown) 56% (48%); discolored urine (orange, red, brown) 52% (41%); discolored skin (yellow) 12% (83%); increased central venous pressure (CVP) 33% (47%); ventricular arrhythmias (AV block, tachycardia, ventricular premature contractions) 15% (78%); ecchymosis/petechiae 8% (50%); bradycardia 6% (67%); vomiting 35% (72%); diarrhea 15% (50%); anorexia 8% (25%); tachypnea 15% (50%); dyspnea 14% (71%); pulmonary edema 12% (67%); harsh lung sounds/crackles 8% (50%); pleural effusion 6% (67%); fever 17% (40%); death/euthanasia 15% (63%); peripheral edema 8% (25%); hemoglobinuria 6% (67%); dehydration 6% (33%).

Adverse reactions occurring in 4% of the dogs treated with *Oxyglobin*® include: coughing, disseminated intravascular coagulopathy, melena, nasal discharge/crusts (red), peritoneal effusion, respiratory arrest, and weight loss (5–7% body weight). Adverse reactions occurring in less than 2% of the dogs treated with *Oxyglobin*® included: abdominal discomfort on palpation, acidosis, cardiac arrest, cardiovascular volume overload (by echocardiography), collapse, cystitis, dark stool, discolored soft stool (red-brown) and tongue (purple), focal hyperemic areas on gums, forelimb cellulitis/lameness, hematemeses or hemoptysis (unable to differentiate), hypernatremia, hypotension, hypoxemia, lack of neurologic responses, left forebrain signs, nystagmus, pancreatitis, pendulous abdomen, polyuria, pulmonary thromboembolism, ptosis, reddened pinnae with papules/head shaking, reduction in heart rate, thrombocytopenia (worsening), and venous thrombosis.

Small amounts of unstabilized hemoglobin (<5%) may be excreted through the kidneys, resulting in transient discoloration (red) of the urine following the infusion. This discoloration of the urine should not be interpreted as due to intravascular hemolysis and has no effect on renal function.

In clinical use, *Oxyglobin*® has not been demonstrated to affect platelet function or impair coagulation.

Increases in aspartate aminotransferase (AST) and alanine aminotransferase (ALT) not associated with histopathologic changes in the liver, increase in serum total protein, and hemoglobinuria may also be seen.

Reproductive/Nursing Safety

Safe use in breeding dogs and pregnant or lactating bitches has not been determined.

Overdosage/Acute Toxicity

The clinical signs associated with *Oxyglobin*® administered at 1, 2, and 3 times the recommended dose twice, 3 days apart include yellow-orange discoloration of skin, ear canals, pinnae, mucous membranes (gums), and sclera, red-dark-green-black discoloration of feces, brown-black discoloration of urine, red spotting of skin and/or lips (less common), decreased appetite and thirst, vomiting, diarrhea, and decreased skin elasticity. The frequency and/or in-

tensity of these signs increased with repeated and increasing doses. Healthy dogs administered 3X overdoses twice, all survived.

Overdosage or an excessively rapid administration rate (*i.e.*, >10 mL/kg/hr) may result in circulatory overload.

Drug Interactions

Other than concerns with compatibility, (no specific drug interactions have been noted).

Laboratory Considerations

- The presence of *Oxyglobin*® in serum may cause artifactual increases or decreases in the results of serum chemistry tests, depending on the type of analyzer and reagents used. May cause false increases in **AST**, or **creatinine**. May cause false decreases in **LDH**. May cause unacceptable interference with **GGT**, **albumin**, or **bilirubin**.
- There is reportedly no interference with directly measured hemoglobin tests, but due to the dilutional effects of *Oxyglobin*®, PCV and RBC count are not accurate measures of the degree of anemia for 24 hours following administration. **Prothrombin time** (PT) and **activated partial thromboplastin time** (aPTT) determined using methods that are mechanical, magnetic and light scattering are accurate, but optical methods are not reliable while *Oxyglobin*® is present.
- **Urine dipstick** measurements (*i.e.*, pH, glucose, ketones, protein) are inaccurate while gross discoloration of the urine is present.

Doses

■ DOGS:

- a) For labeled indications: One-time dose of 10–30 mL/kg IV at a rate of up to 10 mL/kg/hr.
May be warmed to 37°C prior to administration. Blood transfusions are not contraindicated in dogs which receive *Oxyglobin*® nor is *Oxyglobin*® contraindicated in dogs which have previously received a blood transfusion. There is no need for typing or crossmatching before use. Should be administered using aseptic technique via a standard intravenous infusion set and catheter through a central or peripheral vein at a rate of 10 mL/kg/hr. Do not administer with other fluids or drugs via the same infusion set. Do not add medications or other solutions to the bag. Do not combine the contents of more than one bag. (Package Insert; *Oxyglobin*®—Biopure)
- b) For resuscitation of trauma patients in shock with or without hemorrhage: Empirically, 3–5 mL/kg with concurrent crystalloid at ½ to 2 times maintenance. (Gfeller 2002)
- c) To provide a “bridge” until immunosuppressive drugs take effect in dogs with IMHA with a transfusion reaction: 7–10 mL/kg q12h can maintain hemoglobin levels above 3.5 g/dl; higher doses 30 mL/kg may provide oxygen carrying support for 48–72 hours. (Macintire 2006c)

Monitoring

- Hgb; clinical signs of adequate tissue oxygenation
- Signs of circulatory overload (CVP)
- Other adverse effects (see above)

Client Information

- Clients should be informed of the cost/risk/benefit profile for this agent before use.

Chemistry/Synonyms

Oxyglobin® is a sterile, clear, dark purple solution containing 13 g/dl purified, polymerized hemoglobin of bovine origin in a modified lactated Ringer's solution. It has an osmolality of 300 mOsm/kg and

a pH of 7.8. Less than 5% of the hemoglobin are as unstabilized tetramers, and approximately 50% have a molecular weight between 65 and 130 kD, with no more than 10% having a molecular weight >500 kD. The product contains less than the detectable level of 3.5 mcg/mL free-glutaraldehyde and 0.05 EU/mL, endotoxin.

Storage/Stability/Compatibility

The product remains stable at room temperature or refrigerated (2°–30°C) for up to 3 years; expiration date is printed on the bag. Outdated product is not returnable. Do not freeze. It must remain in its over wrap during storage; once removed, it should be used within 24 hours. The foil over wrap serves as an oxygen barrier, protecting the hemoglobin from conversion to methemoglobin.

The manufacturer states that *Oxyglobin*® is physically **compatible** with any other IV fluid, but should not be mixed with other solutions or medications in the bag; other intravenous solutions and medications may be administered via a separate site and line, however.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Hemoglobin Glutamer-200 (bovine) in 60 mL and 125 mL ready to use infusion bags; *Oxyglobin*® (Biopure); (Rx). Approved for use in dogs.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. It is prohibited to be at racing premises. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None in USA at present

HEPARIN SODIUM HEPARIN CALCIUM

(*hep-ah-rin*)

ANTICOAGULANT

Prescriber Highlights

- ▶ Parenteral anticoagulant used primarily for treatment of DIC (use controversial) & thromboembolic disease
- ▶ Contraindications: Known hypersensitivity, severe thrombocytopenia, or uncontrollable bleeding (caused by something other than DIC)
- ▶ Adverse Effects: Most common are bleeding & thrombocytopenia
- ▶ Protamine may reverse effects
- ▶ Intensive monitoring required

Uses/Indications

Heparin's primary uses in small animal medicine has included treatment of Disseminated Intravascular Coagulation (DIC) and prophylaxis of thromboembolic disease. In horses, it has been used in the treatment of DIC and as prophylactic therapy for laminitis (unproven efficacy).

Use for treating DIC has become increasingly controversial. The most recent evidence suggests that heparin not be used during DIC in patients with concurrent inflammatory processes.

Pharmacology/Actions

Heparin acts on coagulation factors in both the intrinsic and extrinsic coagulation pathways. Low concentrations of heparin when combined with antithrombin III inactivate factor X_a and prevent the conversion of prothrombin to thrombin. In higher doses, heparin inactivates thrombin, blocks the conversion of fibrinogen to fibrin and when combined with antithrombin III inactivates factors IX, X, XI, XII. By inhibiting the activation of factor XIII (fibrin stabilizing factor), heparin prevents the formation of stable fibrin clots. While heparin will inhibit the reactions that lead to clotting, it does not significantly change the concentrations of clotting factors. Heparin does not lyse clots, but it can prevent the growth of existing clots.

Heparin causes increased release of lipoprotein lipase, thereby increasing the clearance of circulating lipids and boosting plasma levels of free fatty acids.

Pharmacokinetics

Heparin is not absorbed by the gut if administered orally; it must be given parenterally to be effective. Anticoagulant activity begins immediately after direct IV bolus injection, but may take up to one hour after deep SC injection. When heparin is given by continuous IV infusion, an initial bolus must be administered for full anticoagulant activity to begin.

Heparin is extensively protein bound, primarily to fibrinogen, low-density lipoproteins and globulins. It does not appreciably cross the placenta or enter milk.

Heparin's metabolic fate is not completely understood. The drug is apparently partially metabolized by the liver and also inactivated by the reticuloendothelial system. Serum half-lives in humans averages 1–2 hours.

In healthy dogs, bioavailability after subcutaneous injection is about 50%. When 200 units/kg were administered to healthy dogs SC, plasma heparin concentrations were in the therapeutic range between 1 and 6 hours after administration. (Diquelou, Barbaste et al. 2005)

Contraindications/Precautions/Warnings

Heparin is contraindicated in patients hypersensitive to it, having severe thrombocytopenia or uncontrollable bleeding (caused by something other than DIC). One author (Green 1989) states that with DIC "heparin should not be given to actively bleeding patients that have severe factor depletion and thrombocytopenia, as fatal hemorrhage may result."

Use for treating DIC has become increasingly controversial. The most recent evidence suggests that heparin should not be used during DIC in patients with concurrent inflammatory processes. Until further evidence suggests practices to the contrary, heparin should be used with extreme caution in both human and veterinary patients with dysfunctional interactions between inflammatory and hemostatic systems and the endothelium. (Bateman 2005a)

Do not administer IM as heparin may cause hematoma formation. Hematomas, pain, and irritation may occur after deep SC dosing.

Dogs with renal insufficiency may have lower plasma levels and faster elimination rates of heparin; dosage adjustment may be required.

Adverse Effects

Bleeding and thrombocytopenia are the most common adverse effects associated with heparin therapy. Because heparin is derived from bovine or porcine tissues, hypersensitivity reactions may be possible. Less commonly encountered adverse effects that have been reported in animals and/or humans include vasospastic reactions

(after several days of therapy), osteoporosis and diminished renal function (after long-term, high-dose therapy), rebound hyperlipidemia, hyperkalemia, alopecia, suppressed aldosterone synthesis and priapism. In horses, high IV dosages of heparin may cause agglutination of red cells and a decrease in hematocrits.

Reproductive/Nursing Safety

While heparin does not cross the placenta and is generally felt to be the anticoagulant of choice during pregnancy, its safe use in pregnancy has not been firmly established and pregnancy outcomes may be unfavorable. It should be used cautiously and only when clearly necessary. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Heparin is not excreted into milk.

Overdosage/Acute Toxicity

Overdosage of heparin is associated with bleeding. Clinical signs that could be seen before frank bleeding occurs include hematuria, tarry stools, petechiae, bruising, etc. Protamine can reverse heparin's effects; see the Protamine monograph for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving heparin and may be of significance in veterinary patients:

- **ASPIRIN**: May increase the risk for hemorrhage
- **DEXTRAN**: May increase the risk for hemorrhage
- **NSAIDS**: May increase the risk for hemorrhage
- **WARFARIN**: May increase the risk for hemorrhage
- The following drugs may partially counteract heparin's anticoagulant effects: **ANTIHISTAMINES**, **NITROGLYCERIN** (IV), **PROPYLENE GLYCOL**, **DIGOXIN**, and **TETRACYCLINES**.

Laboratory Considerations

- Unless heparin is administered by continuous infusion, it can alter prothrombin time, (PT), which can be misleading in patients also receiving a coumarin or an indanedione anticoagulant.
- Heparin can interfere with the results of the **BSP** (sulfobromophthalein, bromosulfophthalein) test by changing the color intensity of the dye and shifting the absorption peak from 580 nm to 595 nm.
- Heparin can cause falsely elevated values of serum **thyroxine** if using competitive protein binding methods of determination. Radioimmunoassay (RIA) and protein bound iodine methods are apparently unaffected by heparin.
- When heparin is used as an anticoagulant *in vitro* (e.g., in **blood collection containers**), white cell counts should be performed within 2 hours of collection. Do not use heparinized blood for platelet counts, erythrocyte sedimentation rates, erythrocyte fragmentation tests, or for any tests involving complement or isoagglutinins. Errors in blood gas determinations for CO₂ pressure, bicarbonate concentration, or base excess may occur if heparin encompasses 10% or more of the blood sample.

Doses

■ DOGS & CATS:

For adjunctive treatment of DIC (See Contraindications/Warnings above): **Note**: Heparin therapy may be only one aspect of successful treatment of DIC. Alleviation of the precipitating causes, administration of fluids, blood, aspirin, and diligent monitoring of coagulation tests (aPTT, PT), fibrin degradation products, and

fibrinogen may all be important factors in the treatment of DIC. Doses of heparin are controversial; dosage ranges and methods may vary widely depending on the clinician/author.

- a) 75 Units/kg SC three times daily (Wingfield and Van Pelt 1989)
- b) Add 5,000 U of heparin/500 mL warmed whole blood 30 minutes before transfusion. Alternatively, give 10–150 U/kg SC q12h. Heparin must be tapered over 48 hours or a “rebound effect” may occur. (Feldman 1985)
- c) After pH has been corrected and perfusion maximized, transfuse heparinized whole fresh blood or plasma (75 U/kg heparin) one time. Then begin mini-dose heparin therapy at 5–10 U/kg/hour by continuous IV infusion or 75 U/kg SC q8h. Continue without interruption until DIC has completely disappeared. With these doses, bleeding risk is negligible and aPTT monitoring not necessary, although thrombocytopenia may develop. (Slappendel 1989)
- d) Before administering heparin, provide sufficient fresh whole blood to maintain platelet counts above 30,000/microliter and fibrinogen levels over 50 mg/dl. Then give heparin at 50–100 U/kg SC q6h. Alternatively, dose heparin sufficiently to increase aPTT to 1.5–2 times normal (may be more effective in patients susceptible to thromboembolization). (Green 1989)

For adjunctive treatment of thromboembolic disease:

- a) For feline arterial thromboembolism: 250–300 U/kg SC q8h. First dose is administered IV to cats showing signs of shock. Monitoring aPTT (1.5–2.5 fold) and ACT (15–20 sec) should be regarded as rough guidelines only, as these may still result in heparin levels below the recommended therapeutic range. (Smith 2004)
- b) Dogs: 200–500 U/kg subcutaneously every 8 hours; target aPTT to 1.5–2 times pretreatment value (Brooks 2000)
- c) For maintenance therapy for arterial thromboembolic disease in cats: 250–300 Units/kg SC every 8 hours for the initial in-hospital therapy. (Lunsford and Mackin 2007)
- d) For maintenance therapy for pulmonary thromboembolism in small animals: 200–500 Units/kg SC every 8 hours and then adjusted to reach a target aPTT of 1.5–2 times the (pre)treatment values or an anti-factor Xa activity between 0.35–0.7 U/mL. Warfarin is also given concurrently. (Lunsford and Mackin 2007)
- e) For canine arterial thrombosis and thromboembolism: Keep dog in a quiet and warm place; give analgesics if necessary. Give heparin initially at 220 U/kg IV. Correct dehydration and dilute blood by administering electrolyte solutions. Dextran products may be helpful. Follow-up doses of heparin should be started low and increased until aPTT is 2–2.5 times normal. After 3–5 days of therapy, gradually reduce heparin over 48–72 hours while dog is put on oral anticoagulant therapy (see warfarin monograph). (Suter 1989)

To prevent clots forming when performing closed chest lavage with pyothorax:

- a) Add 1000 U of heparin per liter of lavage fluid (warm normal saline). This fluid is instilled at 20 mL/kg twice daily for 5–7 days. Antibiotics (often penicillin) or enzymes (e.g., streptokinase) may also be added to fluid. (Berkwitt and Berzon 1988)

For adjunctive therapy of acute complicated or severe pancreatitis in dogs:

- a) 50–75 U/kg SC twice a day to three times a day; may reduce thromboembolic tendencies, but efficacy is unknown and heparin is not indicated in all cases (Bunch 1988)

For detection of lipoprotein lipase activity (heparin stimulation test):

- a) Measure serum lipids just before and 15 minutes after heparin at 100 U/kg IV. Lack of increase in lipolytic activity is suggestive of lipoprotein lipase deficiency. (Kay, Kruth, and Twedt 1988)

■ HORSES:

For adjunctive treatment of DIC:

Note: Heparin therapy may be only one aspect of successful treatment of DIC. Alleviation of the precipitating causes, administration of fluids, blood, aspirin, and diligent monitoring of coagulation tests (APTT, PT), fibrin degradation products, and fibrinogen may all be important factors in the treatment of DIC.

- a) 80–100 U/kg IV q4–6h (may be added to fluids and given as a slow drip). Low grade DIC may be treated with 25–40 U/kg SC 2–3 times a day. (Byars 1987)

As adjunctive therapy in endotoxemic shock:

- a) 40 Units/kg IV or SC 2–3 times a day may prevent the development of microthrombi; additional studies are required to confirm positive benefits (Semrad and Moore 1987)

As adjunctive therapy in the prevention of laminitis:

- a) 25–100 Units/kg subcutaneously 3 times daily. Higher doses used when a thrombotic event is underway, lower dosages should have fewer adverse effects and still have antithrombotic activity. Ideally, APTT and ACT should be monitored. Targets are 1.5–2.5 times baseline for APTT and 1.2–1.4 times baseline for ACT. (Brumbaugh, Lopez et al. 1999)

Monitoring

Note: The frequency of monitoring is controversial and is dependent on several factors, including heparin dose, patient's condition, concomitant problems, etc. Because of the high incidence of hemorrhage associated with heparin use, frequent monitoring of aPTT is essential early in therapy (particularly using higher dosages) and in critically ill animals.

- While whole blood clotting time (WBCT), partial thromboplastin time (PTT), and activated partial thromboplastin times (aPTT) may all be used to monitor therapy, APTT is most often recommended;
- Platelet counts and hematocrit (PCV) should be done periodically;
- Occult blood in stool and urine; other observations for bleeding;
- Clinical efficacy

Client Information

- Because of the intense monitoring necessary with heparin's use and the serious nature of the disease states in which it is used, this drug should be utilized only by professionals familiar with it, preferably in an inpatient setting.

Chemistry/Synonyms

Heparin is an anionic, heterogeneous sulfated glycosaminoglycan molecule with an average molecular weight of 12,000 that is found naturally in mast cells. It is available commercially as either sodium or calcium salts and is obtained from either porcine intestinal mucosa (both calcium and sodium salts) or from bovine lung tissue (sodium salt only). Heparin sodium and calcium occur as white

or pale-colored, amorphous, hygroscopic powders having a faint odor. Both are soluble in water and practically insoluble in alcohol; the commercial injections have a pH of 5–7.5. Heparin potency is expressed in terms of USP Heparin units and values are obtained by comparing against a standard reference from the USP. The USP requires that potencies be not less than 120 units/mg on a dried basis for heparin derived from lung tissue, and 140 units/mg when derived from all other tissue sources.

Heparin sodium may also be as: heparinum natricum, sodium heparin, and soluble heparin; many trade names are available.

Storage/Stability/Compatibility

Heparin solutions should be stored at room temperature (15–30°C) and not frozen. Avoid excessive exposure to heat.

Heparin sodium is reportedly physically **compatible** with the following intravenous solutions and drugs: amino acids 4.25%-dextrose 25%, dextrose-Ringer's combinations, dextrose-lactated Ringer's solutions, fat emulsion 10%, Ringer's injection, Normosol R, aminophylline, amphotericin B with or without hydrocortisone sodium phosphate, ascorbic acid injection, bleomycin sulfate, calcium gluconate, cephapirin sodium, chloramphenicol sodium succinate, clindamycin phosphate, dimenhydrinate, dopamine HCl, erythromycin gluceptate, isoproterenol HCl, lidocaine HCl, methylprednisolone sodium succinate, metronidazole with sodium succinate, nafcillin sodium, norepinephrine bitartrate, potassium chloride, prednisolone sodium succinate, promazine HCl, sodium bicarbonate, verapamil HCl, and vitamin B-complex with or without vitamin C.

Heparin **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: dextrose-saline combinations, dextrose in water, lactated Ringer's injection, saline solutions, ampicillin sodium, cephalothin sodium, dobutamine HCl, hydrocortisone sodium succinate, methicillin sodium, oxytetracycline HCl, penicillin G sodium/potassium, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Heparin sodium is reported physically **incompatible** when mixed with the following solutions or drugs: sodium lactate 1/6 M, amikacin sulfate, chlorpromazine HCl, codeine phosphate, cytarabine, daunorubicin HCl, diazepam, doxorubicin HCl, droperidol HCl with and without fentanyl citrate, erythromycin lactobionate, gentamicin sulfate, hyaluronidase, kanamycin sulfate, levorphanol bitartrate, meperidine HCl, methadone HCl, morphine sulfate, pentazocine lactate, phenytoin sodium, polymyxin B sulfate, streptomycin sulfate, and vancomycin HCl.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Heparin Sodium Injection: 1000 U/mL, 2000 U/mL, 2500 U/mL, 5000 U/mL, 10,000 U/mL, 20,000 U/mL, & 40,000 U/mL in 0.5, 1, 2, 4, 5, 10, and 30 mL amps, vials and multi-dose vials (depending on concentration and manufacturer); generic; (Rx).

Heparin Unit-Dose Sodium Injection: 1000 U/dose, 2500 U/dose, 5000 U/dose, 7500 U/dose, 10,000 U/dose and 20,000 U/dose in 1, 10, and 30 mL *Dosette* vials, 0.5 mL & 1 mL *Tubex*, 0.5, 1, 4 and 10 mL vials, and 1 mL fill in 2 mL *Carpject* (depending on concentration and manufacturer); generic; (Rx)

Heparin Sodium and 0.9% Sodium Chloride Injection: 1000 and 2000 units in 500 mL and 1000 mL, respectively; in *Viaflex* (Baxter Healthcare); (Rx)

Heparin Sodium and 0.45% Sodium Chloride Injection: 12,500 and 25,000 units in 250 mL (12,500 only) and 500 mL; (Abbott); (Rx)

Heparin Sodium Lock Flush Solution— (IV use) Injection: 1 unit/mL in 1, 2, 2.5, 5 & 10 mL syringes; 10 U/mL and 100 U/mL in 1, 2, 5, 10 mL (regular and preservative free), 30 mL and 50 mL vials; 1 (regular and preservative free) and 2 mL *Dosette* vials; 1, 2.5 mL *Dosette* cartridge needle units; 1 mL amps; 1, 2, 2.5, 3, and 5 mL disposable syringes; *Hep-Lock®* and *Hep-Loc® U/P* (Elkins-Sinn); *Hepflush-10®* (American Pharmaceutical Partners); *Heparin I.V. Flush* (Medefil); generic; (Rx)

HETASTARCH

(het-a-starch)

COLLOID VOLUME EXPANDER

Prescriber Highlights

- ▶ Volume expander used to treat hypovolemia where colloidal therapy required
- ▶ Contraindications: Severe heart failure, severe bleeding disorders, & patients in oliguric or anuric renal failure
- ▶ Caution: Thrombocytopenia, patients undergoing CNS surgery; liver disease
- ▶ May cause volume overload: Use with caution in patients with renal dysfunction, congestive heart failure, or pulmonary edema
- ▶ Adverse Effects: Coagulopathies possible; too rapid administration to small animals (especially cats) may cause nausea/vomiting; hypersensitivity reactions possible but very rare

Uses/Indications

In hypovolemic patients where total protein is less than 3.5 g/dl and crystalloid therapy is likely to reduce this level further, colloid therapy (plasma, dextran or hetastarch) should be considered as part of intravascular volume restoration. It is often used when colloid therapy is required and blood products are unavailable, or time is of the essence and the wait for crossmatching is unacceptable. Because of the expense, hetastarch is generally used only in small animals.

Pharmacology/Actions

Hetastarch acts as a plasma volume expander by increasing the oncotic pressure within the intravascular space similarly to either dextran or albumin. Maximum volume expansion occurs within a few minutes of the completion of infusion. Duration of effect is variable, but may persist for 24 hours or more. When added to whole blood in humans, hetastarch causes an increase in erythrocyte sedimentation rate.

Pharmacokinetics

Lower molecular weight molecules, (less than 50,000) are rapidly excreted by the kidneys; larger molecules are slowly degraded enzymatically to a size where they then can be excreted. About 40% of a dose is excreted in the first 24 hours after infusion. After about 2 weeks, practically all of the drug is excreted.

Contraindications/Precautions/Warnings

In humans, hetastarch is contraindicated in patients with severe heart failure, severe bleeding disorders and patients in oliguric or anuric renal failure.

It is believed that significant bleeding can occur if hetastarch is used in animals with compromised coagulation systems. For example, use in patients with von Willebrand's disease could significantly increase the risk for bleeding.

Because of the danger of volume overload, use of hetastarch for the treatment of shock not accompanied by hypovolemia may be hazardous. As it has no oxygen carrying capacity, hetastarch is not a replacement for whole blood or red blood cells.

Because of its effect on platelets, hetastarch should be used with caution in patients with thrombocytopenia and with extreme caution in patients undergoing CNS surgery. Because of its effects on indirect serum bilirubin levels, hetastarch should be used with caution in patients with liver disease.

Because of the threat of volume overload, hetastarch should be used in caution in patients with renal dysfunction, congestive heart failure or pulmonary edema.

Adverse Effects

Hetastarch can affect platelet function and clotting tests can be transiently prolonged. It is less antigenic than dextran, but can cause sensitivity reactions and interfere with antigen-antibody testing. Anaphylactic reactions and coagulopathies are considered to occur rarely, however.

When given via rapid infusion to cats, hetastarch may cause signs of nausea and vomiting; if administered over 15–30 minutes, these signs are eliminated. At recommended dosages, hetastarch may cause minor changes in clotting times and platelet counts due to direct (precipitation of factor VIII) and dilutional causes. Clinically these effects are usually insignificant, but patients with preexisting coagulopathies may be predisposed to further bleeding.

In humans, increases in serum indirect bilirubin have occurred occasionally. No effect on other liver function tests were noted and the increases subsided over several days. Serum amylase levels may be falsely elevated for several days after hetastarch is administered. While clinically insignificant, the changes may preclude using serum amylase to diagnosis or monitor patients with acute pancreatitis.

Circulatory overload leading to pulmonary edema is possible, particularly when large dosages are administered to patients with diminished renal function. Do not give intramuscularly as bleeding, bruising, or hematomas may occur.

Reproductive/Nursing Safety

Hetastarch's safety during pregnancy has not been established, but no untoward effects have apparently been reported. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether hetastarch is excreted in milk, but it is unlikely to pose much risk to offspring.

Overdosage/Acute Toxicity

Overdosage could result in volume overload in susceptible patients. Dose and monitor fluid status carefully.

Drug Interactions

Hetastarch apparently has no drug interactions that are clinically significant.

Doses**■ DOGS/CATS:**

For use as a plasma volume expander in shock: **Note:** Rate of administration is determined by individual patient requirements (*i.e.*, blood volume, indication, and patient response); adequate monitoring for successful treatment of shock is mandatory. The following dosages are NOT “Give and forget”; they should be used as general guidelines for treatment.

- Shock bolus (resuscitation): 10–20 mL/kg in dogs and 5–10 mL/kg in cats. (Petrollini 2003)
- Shock bolus (resuscitation): 10–20 mL/kg in dogs and 5–10 mL/kg in cats.

As an infusion: Dogs: 1–2 mL/kg/hr; not to exceed 20 mL/kg in a 24 hour period; Cats: 1–2 mL/kg/hr; not to exceed 10 mL/kg in a 24 hour period (Hopper 2006c)

- Dogs: 20 mL/kg /day; cats: 10/mL/kg/day. Rate of administration depends on the condition treated. For emergent situations, it can be given as a slow bolus over 15–30 minutes. For supporting colloid oncotic pressure in hypoalbuminemic patients, it can be given as a 24-hour infusion with low-rate crystalloid infusion. (Martin 2004)
- For shock resuscitation, standard dose is 20 mL/kg. The dose is given as an IV bolus (slower in the cat). When used for colloid oncotic support the dose is given over 24 hours. Rapid administration to cats can cause nausea and vomiting. Patients may have elevations in prothrombin time and activated partial thromboplastin time without evidence of bleeding. (Barton 2002a)

■ HORSES:

- Adult horses: 8–10 mL/kg/day. Foals who require rapid volume support: 3–5 mL/kg in addition to crystalloids. May also be used in horses that are hypo-oncotic, but well hydrated at: 0.5–1 mL/kg per hour, up to 10 mL/kg/day. (Magdesian 2004)

Monitoring

- Other than the regular monitoring performed in patients that would require volume expansion therapy, there is no inordinate monitoring required specific to hetastarch therapy, but consider monitoring coagulation parameters particularly in high risk patients or when using high dosages of hetastarch

Client Information

- As hetastarch is used in an in-patient setting only, the two factors to consider when communicating with clients are the drug's cost and the reasons for using colloid therapy.

Chemistry/Synonyms

A synthetic polymer derived from a waxy starch, hetastarch is composed primarily of amylopectin. To avoid degradation by serum amylase, hydroxyethyl ether groups are added to the glucose units. It has an average molecular weight of 450,000, but ranges in size from about MW 10,000–1,000,000. Hetastarch occurs as a white powder. It is very soluble in water and insoluble in alcohol.

The commercially available colloidal solution appears as a clear, pale yellow to amber solution. In 500 mL of the commercial preparation containing hetastarch 6% and 0.9% sodium chloride, there are 77 mEq of sodium and chloride. It has an osmolality of 310 mOsm/L and a pH of about 5.5.

The product in lactated electrolyte solution (*Hextend*®) contains 143 mEq/L of sodium, 124 mEq/L of chloride, 28 mEq/L of lactate, 5 mEq/L of calcium, 3 mEq/L of potassium, 0.9 mEq/L of magnesium, and 0.99 grams/L of dextrose. These values approximate what is found in human plasma.

Hetastarch may also be known by the following synonyms: etherified starches, HES, and hydroxyethyl starch; many trade names are available.

Storage/Stability/Compatibility

Hetastarch 6% in 0.9% NaCl or lactated electrolyte should be stored at temperatures less than 40°C; freezing should be avoided. Exposure to temperature extremes may result in formation of a crystalline precipitate or a color change to a turbid deep brown. Do not use should this occur.

The following drugs are reported **compatible** at Y-sites with hetastarch: cimetidine, diltiazem, enalaprilat. For *Hextend*®: Do not administer simultaneously with blood through the same administration set as there is a risk of coagulation.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Hetastarch Injection: 6% (6 g/100 mL) in 0.9% sodium chloride in 500 mL IV infusion bottles & single-dose containers; *Hespan*® (B.Braun Medical); 6% *Hetastarch* (Hospira); (Rx)

Hetastarch Injection: 6% (6 g/100 mL) in lactated electrolyte in 500 mL IV infusion single-dose containers; *Hextend*® (Hospira), generic; (Rx)

HYALURONATE SODIUM SODIUM HYALURONATE

(hy-al-yoo-ron-nate) Hyalovet®, Hyvisc®, Legend®

MUCOPOLYSACCHARIDE**Prescriber Highlights**

- ▶ Parenteral, high viscosity mucopolysaccharide used for synovitis
- ▶ Contraindications: None on label
- ▶ Adverse Effects: Local reactions possible
- ▶ Different products have different dosages, etc; check label before using

Uses/Indications

Hyaluronate sodium (HS) is useful in the treatment of synovitis not associated with severe degenerative joint disease. It may be helpful to treat secondary synovitis in conditions where full thickness cartilage loss exists.

The choice of a high molecular weight product (MW >1x10⁶) versus a low molecular weight one is quite controversial. One author (Nixon 1992) states that “. . . low molecular weight products (which tend to be less expensive) can be equally efficacious in ameliorating signs of joint disease. When synovial adhesions and pannus are to be avoided (as in most surgeries for carpal and fetlock fracture fragment removal), higher molecular weight preparations are recommended because they inhibit proliferation of synovial fibroblasts.”

Pharmacology/Actions

Hyaluronate sodium (HS) is found naturally in the connective tissue of both man and animals and is identical chemically regardless of species. Highest concentrations found naturally are in the synovial fluid, vitreous of the eye and umbilical cord. Surfaces of articular cartilage are covered with a thin layer of a protein-hyaluronate complex; hyaluronate is also found in synovial fluid and the cartilage matrix. The net effects in joints include a cushioning effect, reduction of protein and cellular influx into the joint, and a lubricating effect. Hyaluronate has a direct antiinflammatory effect in joints by scavenging free radicals and suppressing prostaglandins.

Pharmacokinetics

No specific information located.

Contraindications/Precautions/Warnings

No contraindications to HS's use are noted on the label. HS should not be used as a substitute for adequate diagnosis; radiographic examinations should be performed to rule out serious fractures. Do not perform intra-articular injections through skin that has been recently fired or blistered, or that has excessive scurf and counterirritants on it.

Adverse Effects

Some patients may develop local reactions manifested by heat, swelling, and/or effusion. Effects generally subside within 24–48 hours; some animals may require up to 96 hours for resolution. No treatment for this effect is recommended. When used in combination with other drugs, incidence of flares may actually be higher. No systemic adverse effects have been noted.

Reproductive/Nursing Safety

While HS is unlikely to cause problems, safe use in breeding animals has not been established and most manufacturers caution against its use in these animals.

Overdosage/Acute Toxicity

Acute toxicology studies performed in horses have demonstrated no systemic toxicity associated with overdoses.

Drug Interactions/Laboratory Considerations

None were noted.

Doses

■ HORSES:

- a) Because of the differences in the commercially available products, see each individual product's label for specific dosing information.

■ DOGS:

- a) For the adjunctive treatment of synovitis (rather than the presence of a damaged articular cartilage): Using a high molecular weight compound: 3–5 mg intra-articularly using sterile technique at weekly intervals. Long-term effects are not achieved. (Bloomberg 1992)

Client Information

- HS should be administered by a veterinarian only, using aseptic technique.

Chemistry/Synonyms

Hyaluronate sodium (HS) is the sodium salt of hyaluronic acid which is a naturally occurring high-viscosity mucopolysaccharide.

Hyaluronate sodium may also be known as: hyaluronic acid, and natrii hyaluronas; many trade names are available.

Storage/Stability

Store at room temperature or refrigerate depending on the product used—check label; do not freeze. Protect from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Hyaluronate Sodium: (average MW of 500,000–730,000) 20 mg/mL in 2 mL disposable syringes; *Hyalovet*® (Fort Dodge); (Rx). Approved for use in horses not intended for food.

Hyaluronate Sodium Injection: 2 mL vial for IA administration; 4 mL, & 20 mL vials for IV administration; *Legend*® (Bayer); (Rx). Approved for use in horses not intended for food.

Hyaluronate Sodium Injection: 11 mg/mL in 2 mL syringes; *Hyvisc*® (Boehringer Ingelheim); (Rx). Approved for use in horses not intended for food.

Hyaluronate Sodium: 10 mg/mL (MW 3.5×10^6) in 2 mL disposable syringes; *Hylartin*® V (Pfizer); (Rx). Approved for use in horses not intended for food.

Hyaluronate Sodium: 10 mg/mL (Avg. MW >1 mm Daltons) 2 mL, 6 mL, 10 mL in 2 mL vials; *Hycor*® (Neogen); (Rx). Approved for use in horses, dogs, cats in surgical procedures.

There may also be hyaluronate products in oral supplements.

HUMAN-LABELED PRODUCTS: None

HYDRALAZINE HCL

(hye-dral-a-zeen) Apresoline®

VASODILATOR

Prescriber Highlights

- ▶ Vasodilator drug used primarily for hypertension or adjunctive treatment of heart failure
- ▶ Contraindications: Known hypersensitivity, coronary artery disease, hypovolemia or preexisting hypotension
- ▶ Caution: Severe renal disease, intracerebral bleeding, preexisting autoimmune diseases
- ▶ Adverse Effects: Hypotension, reflex tachycardia, sodium/water retention (if not given concurrently with a diuretic), or GI distress (vomiting, diarrhea)
- ▶ Drug interactions

Uses/Indications

Primary use of hydralazine in veterinary medicine is as an afterload reducer for the adjunctive treatment in CHF in small animals, particularly if mitral valve insufficiency is the primary cause. It is also useful in dogs and cats with large septal defects or severe aortic regurgitation. Hydralazine is usually used in cases where enalapril is not effective in clinical improving dogs with mitral insufficiency. It is used to treat systemic hypertension, particularly in combination with other drugs (e.g., beta-blockers) to offset hydralazine's tendency to cause reflex tachycardia and fluid retention.

Pharmacology/Actions

Hydralazine acts upon vascular smooth muscle and reduces peripheral resistance and blood pressure. It is believed that hydralazine alters cellular calcium metabolism in smooth muscle, thereby interfering with calcium movements and preventing the initiation

and maintenance of the contractile state. Hydralazine has more effect on arterioles than on veins.

In patients with CHF, hydralazine significantly increases cardiac output, and decreases systemic vascular resistance. Cardiac rate may be slightly increased or unchanged, while blood pressure, pulmonary venous pressure, and right atrial pressure may be decreased or unchanged.

When used to treat hypertensive patients (without CHF), increased heart rate, cardiac output and stroke volume can be noted. The renin-angiotensin system can be activated with a resultant increase in sodium and water retention if not given with diuretics or sympathetic blocking drugs.

Parenteral hydralazine administration can cause respiratory stimulation.

Pharmacokinetics

In dogs, hydralazine is rapidly absorbed after oral administration with an onset of action within one hour and peak effects at 3–5 hours. There is a high first-pass effect after oral administration. The presence of food may enhance the bioavailability of hydralazine tablets.

Hydralazine is widely distributed in body tissues. In humans, approximately 85% of the drug in the blood is bound to plasma proteins. Hydralazine crosses the placenta and very small amounts are excreted into the milk.

Hydralazine is extensively metabolized in the liver and approximately 15% is excreted unchanged in the urine. The half-life in humans is usually 2–4 hours, but may be as long as 8 hours.

Specific pharmacokinetic parameters for this drug in veterinary species are limited, but the duration of action of hydralazine in dogs after oral administration is reportedly 11–13 hours. Vasodilating effects occur within one hour and peak within 3 hours of dosing. Food decreases oral bioavailability in dogs by about 63%. At lower doses there is relatively high first pass effect, but this is apparently a saturable process as bioavailability increases with dose. N-acetylation is a primary enzymatic pathway for hydralazine metabolism and this pathway is mostly absent in dogs leading to concerns for increased risks for toxicity.

Contraindications/Precautions/Warnings

Hydralazine is contraindicated in patients hypersensitive to it and those with coronary artery disease. The drug is listed as contraindicated in human patients with mitral valvular rheumatic disease, but it has been recommended for use in small animal patients with mitral valve insufficiency. It is recommended not to use the drug in patients with hypovolemia or preexisting hypotension.

Hydralazine should be used with caution in patients with severe renal disease or intracerebral bleeding. In humans, a syndrome resembling systemic lupus erythematosus (SLE) has been documented after hydralazine use. While this syndrome has not been documented in veterinary patients, the drug should be used with caution in patients with preexisting autoimmune diseases.

Adverse Effects

The most prevalent adverse effects seen in small animals include: hypotension, reflex tachycardia, sodium/water retention (if not given concurrently with a diuretic), and GI distress (vomiting, diarrhea). Initially, transient weakness and lethargy can occur, but usually resolve in 3–4 days. Other adverse effects documented in humans that could occur include: an SLE-like syndrome, lacrimation, conjunctivitis, peripheral neuritis, blood dyscrasias, urinary retention, constipation, and hypersensitivity reactions.

Tachycardias may be treated with concomitant digitalis treatment or a beta-blocker (Caution: beta-blockers may reduce cardiac performance).

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Hydralazine is excreted in milk. According to the American Academy of Pediatrics, hydralazine is compatible with breastfeeding, but exercise caution.

Overdosage /Acute Toxicity

Overdoses may be characterized by severe hypotension, tachycardia or other arrhythmias, skin flushing, and myocardial ischemia. Cardiovascular system support is the primary treatment modality. Evacuate gastric contents and administer activated charcoal using standard precautionary measures if the ingestion was recent and cardiovascular status has been stabilized. Treat shock using volume expanders without using pressor agents if possible. If a pressor agent is required to maintain blood pressure, the use of a minimally arrhythmogenic agent (e.g., phenylephrine or methoxamine) is recommended. Digitalis agents may be required. Monitor blood pressure and renal function diligently.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydralazine and may be of significance in veterinary patients:

- **ACE-INHIBITORS:** May cause additive hypotensive effect; usually used for therapeutic advantage
- **BETA-BLOCKERS:** May cause additive hypotensive effect; usually used for therapeutic advantage
- **DIAZOXIDE:** Potentially could cause profound hypotension
- **DIURETICS:** May cause additive hypotensive effect; usually used for therapeutic advantage
- **FUROSEMIDE:** Hydralazine may increase furosemide's renal effects
- **MAO INHIBITORS:** May cause additive hypotensive effect
- **SYMPATHOMIMETICS** (e.g., **epinephrine**): Hydralazine may cause decreased pressor effect and may cause additive tachycardia

Doses

Because of the sodium/water retention associated with this drug it should be given concurrently with a diuretic. Many clinicians recommend adding a venous dilating agent (e.g., nitroglycerin ointment) to reduce preload.

■ DOGS:

For adjunctive therapy in treatment of heart failure:

- a) Effective dose is 0.5–3 mg/kg PO q12h. Dose must be titrated, starting with a low dose and titrating upwards.

In dogs *not receiving ACE inhibitors*: Get initial baseline assessment (mucous membrane color, capillary refill time, murmur intensity, cardiac size on radiographs, and severity of pulmonary edema). Starting dose is 1 mg/kg PO q12h and repeat assessments made in 12–48 hours. If no response identified, increase dosage to 2 mg/kg q12h. Repeat assessments as above and increase to 3 mg/kg PO q12h If no response. Can be titrated with or without blood pressure monitoring. If BP cannot be monitored titration is performed more slowly and clinical and radiographic signs are monitored.

If blood pressure measurement available, dosage titration can be made more rapidly than above: Measure baseline blood pressure. Administer 1 mg/kg PO. Repeat BP in 1–2 hours and if it has decreased by at least 15 mmHg, administer q12h from then on. If response inadequate, give another 1 mg/kg and repeat BP measurement in 1–2 hours. This may be repeated until a cumulative dose of 3 mg/kg has been given within a 12 hour period. The resulting cumulative dose becomes the dosage to be given q12h.

For dogs with acute, fulminant heart failure due to severe mitral regurgitation and not receiving ACE inhibitors: 2 mg/kg along with IV furosemide. May cause hypotension, but the risks of not effectively treating fulminant pulmonary edema outweigh the risks of treatment.

For dogs receiving ACE inhibitors: Give hydralazine with caution as severe hypotension may occur if dosage not titrated carefully. Begin dosing at 0.5 mg/kg with blood pressure monitoring and increase in 0.5 mg/kg increments until a response is identified to a maximum of 3 mg/kg. Consider referral. (Kittleson 2000), (Kittleson 2007)

- b) When an ACEI is not well tolerated or affordable: hydralazine at 0.5–2 mg/kg PO q12h with either nitroglycerin ointment (½ to 1.5 inches q8–12h cutaneously), or isosorbide dinitrate (0.5–2 mg/kg PO q8h) (Ware and Keene 2000)

For treatment of systemic hypertension:

- a) 0.5–2 mg/kg PO two to three times daily (Morgan 1988)
- b) 0.5–2 mg/kg PO q12h (Stepian 2006a)

■ CATS:

For adjunctive therapy in treatment of heart failure:

- a) See (a) above “For adjunctive therapy in treatment of heart failure in dogs:”, but start titration at 2.5 mg (total dose) and if necessary, increase up to 10 mg. (Kittleson 1985b)

For treatment of systemic hypertension:

- a) 2.5 mg PO twice daily (Morgan 1988)
- b) 2.5 mg (total dose) PO q12–24h (Stepian 2006a)

■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

For adjunctive therapy in treatment of heart failure (afterload reducer):

- a) 0.5 mg/kg IV; for long-term therapy use 0.5–1.5 mg/kg PO q12h (Mogg 1999)

Monitoring

- Baseline thoracic radiographs
- Mucous membrane color
- Serum electrolytes
- If possible, arterial blood pressure and venous PO₂
- Because blood dyscrasias are a possibility, an occasional CBC should be considered.

Client Information

- Compliance with directions is necessary to maximize the benefits from this drug.
- Notify veterinarian if the animal's condition deteriorates or if it becomes lethargic, weak or depressed, (signs of hypotension).

Chemistry/Synonyms

A phthalazine-derivative antihypertensive and vasodilating agent, hydralazine HCl occurs as an odorless, white to off-white crystalline powder with a melting point between 270–280°C and a pK_a of 7.3. One gram is soluble in approximately 25 mL of water or 500 mL of alcohol. The commercially available injection has a pH of 3.4–4.

Hydralazine may also be known as: apressinum, hydralazini, hydrallazine, idralazina, *Alphapress*®, *Apresolin*®, *Apresolina*®, *Bionobal*®, *Cesoline*®, *Hidral*®, *Hydrapres*®, *Hyperex*®, *Hyperphen*®, *Ipolina*®, *Nepresol*®, *Novo-Hylazin*®, *Nu-Hydral*®, *Rolazine*®, *Slow-Apresoline*®, and *Supres*®.

Storage/Stability/Compatibility

Hydralazine tablets should be stored in tight, light resistant containers at room temperature. The injectable product should be stored at room temperature; avoid refrigeration or freezing.

When mixed with most infusion solutions a color change can occur which does not necessarily indicate a loss in potency (if occurred over 8–12 hours).

Hydralazine is reported to be physically **compatible** with the following infusion solutions/drugs: dextrose-Ringer's combinations, dextrose-saline combinations, Ringer's injection, lactated Ringer's injection, sodium chloride solutions, and dobutamine HCl.

Hydralazine is reported to be physically **incompatible** when mixed with 10% dextrose or fructose and is reported to be physically **incompatible** when mixed with the following drugs: aminophylline, ampicillin sodium, chlorothiazide sodium, edetate calcium disodium, hydrocortisone sodium succinate, mephentermine sulfate, methohexital sodium, phenobarbital sodium, and verapamil HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Hydralazine HCl Tablets: 10 mg, 25 mg, 50 mg and 100 mg; *Apresoline*® (Novartis); generic; (Rx)

Hydralazine Injection: 20 mg/mL in 1 mL vials; generic; (Solopak); (Rx)

HYDROCHLOROTHIAZIDE

(hye-droe-klor-oh-thye-a-zide) HydroDIURIL®

THIAZIDE DIURETIC

Prescriber Highlights

- ▶ Thiazide diuretic used for nephrogenic diabetes insipidus, hypertension, calcium oxalate uroliths, hypoglycemia, & diuretic for heart failure
- ▶ Contraindications: Hypersensitivity; pregnancy (relative contraindication)
- ▶ Extreme Caution/Avoid: Severe renal disease, preexisting electrolyte/water balance abnormalities, impaired hepatic function, hyperuricemia, SLE, diabetes mellitus
- ▶ Adverse Effects: Hypokalemia, hypochloremic alkalosis, other electrolyte imbalances, hyperuricemia, GI effects
- ▶ Many possible drug interactions; lab test interactions

Uses/Indications

In veterinary medicine, furosemide has largely supplanted the use of thiazides as a general diuretic (edema treatment). Thiazides are still used for the treatment of systemic hypertension, nephrogenic diabetes insipidus, and to help prevent the recurrence of calcium oxalate uroliths in dogs.

Pharmacology/Actions

Thiazide diuretics act by interfering with the transport of sodium ions across renal tubular epithelium possibly by altering the metabolism of tubular cells. The principle site of action is at the cortical diluting segment of the nephron. Enhanced excretion of sodium, chloride, and water results. Thiazides increase the excretion of potassium, magnesium, phosphate, iodide, and bromide and decrease the glomerular filtration rate (GFR). Plasma renin and resulting aldosterone levels are increased which contribute to the hypokalemic effects of the thiazides. Bicarbonate excretion is increased, but effects on urine pH are usually minimal. Thiazides initially have a hypercalciuric effect, although with continued therapy calcium excretion this is significantly decreased. Uric acid excretion is decreased by the thiazides. Thiazides can cause or exacerbate hyperglycemia in diabetic patients or induce diabetes mellitus in prediabetic patients.

The antihypertensive effects of thiazides are well known and these agents are used extensively in human medicine for treating essential hypertension. The exact mechanism for this effect has not been established.

Thiazides paradoxically reduce urine output in patients with diabetes insipidus (DI). They have been used as adjunctive therapy in patients with neurogenic DI and are the only drug therapy for nephrogenic DI.

Pharmacokinetics

The pharmacokinetics of the thiazides have apparently not been studied in domestic animals. In humans, hydrochlorothiazide is about 65–75% absorbed after oral administration. The onset of diuretic activity occurs in 2 hours; peaks at 4–6 hours. The serum half-life is approximately 5.6–14.8 hours and the duration of activity is 6–12 hours. The drug is apparently not metabolized and is excreted unchanged into the urine. Like all thiazides, the antihypertensive effects of hydrochlorothiazide may take several days to occur.

Contraindications/Precautions/Warnings

Thiazides are contraindicated in patients hypersensitive to any one of these agents or to sulfonamides, and in patients with anuria. In humans, their use is inappropriate during pregnancy in women who are otherwise healthy and have only mild edema.

Thiazides should be used with extreme caution, if at all, in patients with severe renal disease or with preexisting electrolyte or water balance abnormalities, impaired hepatic function (may precipitate hepatic coma), hyperuricemia, lupus (SLE), or diabetes mellitus. Patients with conditions that may lead to electrolyte or water balance abnormalities (e.g., vomiting, diarrhea, etc.) should be monitored carefully.

Adverse Effects

Hypokalemia is one of the most common adverse effects associated with the thiazides but rarely causes clinical signs or progresses, however, monitoring of potassium is recommended with chronic therapy.

Hypochloremic alkalosis (with hypokalemia) may develop, especially if there are other causes of potassium and chloride loss (e.g., vomiting, diarrhea, potassium-losing nephropathies, etc.) or the patient has cirrhotic liver disease. Dilutional hyponatremia and

hypomagnesemia may occur. Hyperparathyroid-like effects of hypercalcemia and hypophosphatemia have been reported in humans, but have not led to effects such as nephrolithiasis, bone resorption, or peptic ulceration.

Hyperuricemia can occur, but is usually asymptomatic.

Other possible adverse effects include: GI reactions (vomiting, diarrhea, etc.), hypersensitivity/dermatologic reactions, GU reactions (polyuria), hematologic toxicity, hyperglycemia, hyperlipidemias, and orthostatic hypotension.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), thiazides are categorized as in class: **C** (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Thiazides may appear in milk and there have been case reports of newborn human infants developing thrombocytopenia when their mothers received thiazides.

Overdosage/Acute Toxicity

Acute overdosage may cause electrolyte and water balance problems, CNS effects (lethargy to coma and seizures), and GI effects (hypermotility, GI distress). Transient increases in BUN have been reported.

Treatment consists of emptying the gut after recent oral ingestion using standard protocols. Avoid giving concomitant cathartics as they may exacerbate the fluid and electrolyte imbalances that may ensue. Monitor and treat electrolyte and water balance abnormalities supportively. Additionally, monitor respiratory, CNS, and cardiovascular status; treat supportively and symptomatically if required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydrochlorothiazide and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Use with thiazides can lead to an increased risk for severe hypokalemia
- **CORTICOSTEROIDS, CORTICOTROPIN:** Use with thiazides can lead to an increased risk for severe hypokalemia
- **DIAZOXIDE:** Increased risk for hyperglycemia, hyperuricemia, and hypotension
- **DIGOXIN:** Thiazide-induced hypokalemia, hypomagnesemia, and/or hypercalcemia may increase the likelihood of digitalis toxicity
- **INSULIN:** Thiazides may increase insulin requirements
- **LITHIUM:** Thiazides can increase serum lithium concentrations
- **METHENAMINE:** Thiazides can alkalize urine and reduce methenamine effectiveness
- **NSAIDS:** Thiazides may increase risk for renal toxicity and NSAIDs may reduce diuretic actions of thiazides
- **NEUROMUSCULAR BLOCKING AGENTS:** Tubocurarine or other non-depolarizing neuromuscular blocking agents response or duration of effect may be increased
- **PROBENECID:** Blocks thiazide-induced uric acid retention (used to therapeutic advantage)

- **QUINIDINE:** Half-life may be prolonged by thiazides (thiazides can alkalinize the urine)
- **VITAMIN D or CALCIUM SALTS:** Hypercalcemia may be exacerbated if thiazides are concurrently administered

Laboratory Considerations

- **AMYLASE:** Thiazides can increase serum amylase values in asymptomatic patients and those in the developmental stages of acute pancreatitis (humans)
- **CORTISOL:** Thiazides can decrease the renal excretion of cortisol
- **ESTROGEN, URINARY:** Hydrochlorothiazide may falsely decrease total urinary estrogen when using a spectrophotometric assay
- **HISTAMINE:** Thiazides may cause false-negative results when testing for pheochromocytoma
- **PARATHYROID-FUNCTION TESTS:** Thiazides may elevate serum calcium; recommend to discontinue thiazides prior to testing
- **PHENOLSULFONPHTHALEIN (PSP):** Thiazides can compete for secretion at proximal renal tubules
- **PHENTOLAMINE TEST:** Thiazides may give false-negative results
- **PROTEIN-BOUND IODINE:** Thiazides may decrease values
- **TRIIODOTHYRONINE RESIN UPTAKE TEST:** Thiazides may slightly reduce uptake
- **TYRAMINE:** Thiazides can cause false-negative results

Doses

■ DOGS:

For treatment of nephrogenic diabetes insipidus:

- a) 0.5–1 mg/kg PO twice daily (Morgan 1988)
- b) 2.5–5 mg/kg PO twice daily (Nichols 1989)

For treatment of systemic hypertension:

- a) 1 mg/kg PO q12–24h; may combine with spironolactone (1–2 mg/kg PO q12 hours) to reduce potassium loss (Brown and Henik 2000)

For treatment of recurrent calcium oxalate uroliths with renal hypercalcuria:

- a) 2 mg/kg q12h PO **Note:** Do not use in patients with absorptive (intestinal) hypercalcuria as hypercalcemia may result (Polzin and Osborne 1985)
- b) 2.2 mg/kg PO q12h; repeat urinalysis q2–4 weeks and monitor serum electrolytes within several weeks of initial dose and within 2 weeks of dosage adjustment (Lulich, Osborne et al. 2000)
- c) 2–4 mg/kg PO q12h (Bartges 2006b)

As a diuretic:

- a) For heart failure In combination with furosemide in patients who have become refractory to furosemide alone: 2–4 mg/kg PO q12h (Kittleson 2000), (Kittleson 2006a)
- b) For ascites secondary to right-sided heart failure; In addition to furosemide (4–6 mg/kg PO q8h), spironolactone (1–2 mg/kg PO q12h), ACE inhibitors, dietary sodium restriction, etc consider: hydrochlorothiazide at 2 mg/kg initially on an every other day bases; monitor electrolytes and renal function. (Connolly 2006)

For treatment of hypoglycemia (with diazoxide):

- a) 2–4 mg/kg PO twice daily (Morgan 1988)

■ CATS:

For treatment of systemic hypertension:

- a) 1 mg/kg PO q12–24h; may combine with spironolactone (1–2 mg/kg PO q12 hours) to reduce potassium loss (Brown and Henik 2000)

- b) 2–4 mg/kg PO q12h. Not effective as a single agent in cats, and may be contraindicated (e.g., chronic renal failure). Possibly helpful acutely with retinal detachment. (Sparkes 2003b)

As a diuretic for heart failure:

- a) In combination with furosemide in patients who have become refractory to furosemide alone: 1–2 mg/kg PO q12h (Kittleson 2000), (Kittleson 2006a)

Client Information

- Clients should contact veterinarian if clinical signs of water or electrolyte imbalance occur. Clinical signs such as excessive thirst, lethargy, lassitude, restlessness, oliguria, GI distress, or tachycardia may indicate electrolyte or water balance problem.

Chemistry/Synonyms

Hydrochlorothiazide occurs as a practically odorless, slightly bitter-tasting, white, or practically white, crystalline powder with pK_as of 7.9 and 9.2. It is slightly soluble in water and soluble in alcohol.

Hydrochlorothiazide may also be known as: hidroclorotiazida, and hydrochlorothiazidum; many trade names are available.

Storage/Stability

Hydrochlorothiazide capsules and tablets should be stored at room temperature in well-closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None. An oral bolus product containing trichlormethiazide and dexamethasone (*Naquasone*®—Schering-Plough) is available for treating udder edema in dairy cattle.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Hydrochlorothiazide Tablets: 25 mg, 50 mg, 100 mg; *HydroDIURIL*® (Merck); *Hydro-Par*® (Parmed); *Ezide*® (Econo Med); generic; (Rx)

Hydrochlorothiazide Capsules: 12.5 mg; *Microzide*® Capsules (Watson); generic; (Rx)

Fixed dose combinations of hydrochlorothiazide with: hydralazine, amiloride, propranolol, triamterene, captopril, reserpine, enalapril, guanethidine, metoprolol, spironolactone, timolol, methyldopa or labetalol are also available.

HYDROCODONE BITARTRATE

(hye-droe-koe-done) Tussigon®, Hycodan®

OPIATE

Prescriber Highlights

- ▶ Opiate agonist used primarily as an antitussive in dogs
- ▶ Contraindications: Hypersensitivity to narcotic analgesic, patients receiving monoamine oxidase inhibitors (MAOIs; Selegiline?), diarrhea caused by a toxic ingestion
- ▶ Caution: Patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), head injuries or increased intracranial pressure, acute abdominal conditions, & geriatric or severely debilitated patients
- ▶ Use extreme caution in patients suffering from respiratory diseases when respiratory secretions are increased or when liquids are nebulized into the respiratory tract
- ▶ Adverse Effects: Sedation, constipation (with chronic therapy), vomiting, or other GI disturbances
- ▶ May mask the clinical signs (cough) of respiratory disease
- ▶ Combination product is a C-III controlled substance

Uses/Indications

Used principally in canine medicine as an antitussive for cough secondary to conditions such as collapsing trachea, bronchitis, or canine upper respiratory infection complex (C-URI, "kennel cough", canine infectious tracheobronchitis). Its use is generally reserved for harsh, dry, non-productive coughs. Hydrocodone may be useful in treating opioid-related behavior problems in dogs and cats (lick granuloma, stereotypies) by providing an exogenous source of opioid, thereby reducing the need for the self-stimulating behavior.

Pharmacology/Actions

While hydrocodone exhibits the characteristics of other opiate agonists, it tends to have a slightly greater antitussive effect than codeine (on a weight basis). The mechanism of this effect is thought to be as a result of direct suppression of the cough reflex on the cough center in the medulla. Hydrocodone tends to have a drying effect on respiratory mucosa and the viscosity of respiratory secretions may be increased; the addition of homatropine MBr (in *Hycodan*® and others) may enhance this effect. Hydrocodone may also be more sedating than codeine, but it is not more constipating.

Pharmacokinetics

In humans, hydrocodone is well absorbed after oral administration and has a serum half-life of about 3.8 hours; antitussive effect usually lasts 4–6 hours in adults.

There does not appear to be any pharmacokinetic data published in dogs. The antitussive action generally persists for 6–12 hours.

Contraindications/Precautions/Warnings

Hydrocodone is contraindicated in cases where the patient is hypersensitive to narcotic analgesics, and those with diarrhea caused by a toxic ingestion (until the toxin is eliminated from the GI tract). All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), and geriatric or severely debilitated patients.

Hydrocodone should be used with caution in patients with head injuries or increased intracranial pressure and acute abdominal conditions as it may obscure the diagnosis or clinical course of these conditions. It should be used with extreme caution in patients

suffering from respiratory diseases when respiratory secretions are increased or when liquids are nebulized into the respiratory tract.

Adverse Effects

Side effects that may be encountered with hydrocodone therapy in dogs include sedation, constipation (with chronic therapy), vomiting or other GI disturbances.

Hydrocodone may mask the clinical signs (cough) of respiratory disease and should not take the place of appropriate specific treatments for the underlying cause of coughs.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*).

It is unknown if hydrocodone enters milk; use with caution.

Overdosage/Acute Toxicity

The initial concern with a very large overdose of *Hycodan*® (or equivalent) would be the CNS, cardiovascular and respiratory depression secondary to the opiate effects.

There were 21 exposures to hydrocodone bitartrate reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.as-pca.org) during 2001–2006. In these cases 18 were dogs and 3 were cats. No clinical signs were reported in these cases.

If the ingestion was recent, emptying the gut using standard protocols should be performed and treatment with naloxone instituted as necessary. The homatropine ingredient may give rise to anticholinergic effects that may complicate the clinical picture, but its relatively low toxicity may not require any treatment. For further information on handling opiate or anticholinergic overdoses, refer to the meperidine and atropine monographs, respectively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydrocodone and may be of significance in veterinary patients:

- **ACEPROMAZINE:** Acepromazine and hydrocodone may cause additive hypotension in dogs with collapsing trachea
- **ANTICHOLINERGIC DRUGS:** May cause additive anticholinergic effects
- **ANTIDEPRESSANTS, TRICYCLIC & MOA INHIBITORS:** Use with hydrocodone may potentiate the adverse effects associated with the antidepressant
- **CNS DEPRESSANTS, OTHER:** Other CNS depressants (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.) may cause increased CNS or respiratory depression when used with hydrocodone.

Doses

■ DOGS:

- a) 0.22 mg/kg PO q6–12h; goal is to suppress coughing without causing excessive sedation (Johnson 2000)
- b) For collapsing trachea: 0.25 mg/kg PO two to four times a day (Prueter 1988b)
- c) For cough: ¼ to 1 tablet (5 mg) once to 4 times daily in small and medium sized dogs. For lick granulomas: 5–10 mg (1–2 tablets) per 20 kg of body weight PO three times daily (Trepanier 1999)
- d) For adjunctive treatment of opioid-related stereotypies, lick granuloma: 0.22–0.25 mg/kg PO q8–12h. Supplies exogenous opioids to decrease the need for self-stimulation. (Siebert 2003c)

■ CATS:

- For adjunctive treatment of opioid-related stereotypies: 1.25–5 mg per cat PO q12h. Supplies exogenous opioids to decrease the need for self-stimulation. (Siebert 2003c)

Monitoring

- Clinical efficacy
- Adverse effects

Chemistry/Synonyms

A phenanthrene-derivative opiate agonist, hydrocodone bitartrate occurs as fine, white crystals or crystalline powder. One gram is soluble in about 16 mL of water; it is slightly soluble in alcohol.

Hydrocodone bitartrate may also be as: hydrocodone tartrate, dihydrocodeinone acid tartrate, hydrocodone acid tartrate, hydrocodoni bitartras, hydrocone bitartrate, *Biocodone*®, *Dicodid*®, *Hydrokon*®, and *Robidone*®.

Storage/Stability/Compatibility

Products should be protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Hydrocodone Bitartrate 5 mg, Homatropine MBr 1.5 mg Tablets: *Tussigon*® (Daniels); *Hycodan*® (Endo); (Rx, C-III)

Hydrocodone Bitartrate Syrup: 5 mg, Homatropine MBr 1.5 mg (per 5 mL) in 473 mL and 3.8 L; *Hycodan*® Syrup (Endo); *Hydromet*® Syrup (Alpharma); *Hydromide*® Syrup (Major); *Hydropane*® Syrup (Watson); (Rx, C-III)

The products listed above are the ones most commonly used in small animal medicine. Other oral tablets and liquids with hydrocodone are available in combination with decongestants (pseudoephedrine, phenylephrine, or phenylpropanolamine), antihistamines (chlorpheniramine), analgesics (acetaminophen, ibuprofen or aspirin) or expectorants (guaifenesin). In the USA, there are no hydrocodone products available as a sole ingredient. All commercially available products containing hydrocodone are Class-III controlled substances.

HYDROCORTISONE HYDROCORTISONE SODIUM SUCCINATE

(hye-droe-kor-ti-zone) Cortef®, Solu-Cortef®

GLUCOCORTICOID

Prescriber Highlights

- ▶ “Benchmark” injectable, oral, & topical glucocorticoid (depending on salt)
- ▶ Has both mineralocorticoid & glucocorticoid activity
- ▶ If using for therapy, goal is to use as much as is required & as little as possible, for as short an amount of time as possible
- ▶ Primary adverse effects are “Cushingoid” in nature with sustained use
- ▶ Many potential drug & lab interactions

Uses/Indications

Because of its rapid effect and relatively high mineralocorticoid effect, hydrocortisone sodium succinate (*Solu-Cortef*®) is the most commonly used form of this medication when an acute glucocorticoid/mineralocorticoid effect is desired (e.g., acute adrenal insufficiency). Corticosteroids have not been shown beneficial in treating hypovolemic shock, but low dose glucocorticoids probably reduce mortality associated with septic shock.

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. 1) Replacement of glucocorticoid activity in patients with adrenal insufficiency, 2) as an antiinflammatory agent, and 3) as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete.

Pharmacology/Actions

Glucocorticoids have effects on virtually every cell type and system in mammals. An overview of the effects of these agents follows:

Cardiovascular System: Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A relatively clinically insignificant positive inotropic effect can occur after glucocorticoid administration. Increased blood pressure can result from both the drugs’ vasoconstrictive properties and increased blood volume that may be produced.

Cells: Glucocorticoids inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes, and the cellular response to mediators of inflammation. Glucocorticoids stabilize lysosomal membranes.

CNS/Autonomic Nervous System: Glucocorticoids can lower seizure threshold, alter mood and behavior, diminish the response to pyrogens, stimulate appetite, and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.

Endocrine System: When animals are not stressed, glucocorticoids will suppress the release of ACTH from the anterior pituitary, thereby reducing or preventing the release of endogenous corticosteroids. Stress factors (e.g., renal disease, liver disease, diabetes) may sometimes nullify the suppressing aspects of exogenously administered steroids. Release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin, and luteinizing hormone (LH) may all be reduced when glucocorticoids are administered at pharmacological doses. Conversion of thyroxine (T₄) to triiodothyronine (T₃) may be reduced by glucocorticoids; and plasma levels of parathyroid hormone increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (ADH) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin-receptors and the post-receptor effects of insulin.

Hematopoietic System: Glucocorticoids can increase the numbers of circulating platelets, neutrophils, and red blood cells, but platelet aggregation is inhibited. Decreased amounts of lymphocytes (peripheral), monocytes, and eosinophils are seen as glucocorticoids can sequester these cells into the lungs and spleen and prompt de-

creased release from the bone marrow. Removal of old red blood cells is diminished. Glucocorticoids can cause involution of lymphoid tissue.

GI Tract and Hepatic System: Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption are decreased while fat absorption is increased. Hepatic changes can include increased fat and glycogen deposits within hepatocytes, increased serum levels of alanine aminotransferase (ALT), and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum alkaline phosphatase levels. Glucocorticoids can cause minor increases in BSP (bromosulfophthalein) retention time.

Immune System (also see Cells and Hematopoietic System): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; inhibit phagocytosis and chemotaxis; antigen processing; and diminish intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high or very high doses and there are species differences in response.

Metabolic effects: Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (e.g., abdomen) and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glycerol are increased. Protein is mobilized from most areas of the body (not the liver).

Musculoskeletal: Glucocorticoids may cause muscular weakness (also caused if there is a lack of glucocorticoids), atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion, and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.

Ophthalmic: Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.

Renal, Fluid, & Electrolytes: Glucocorticoids can increase potassium and calcium excretion; sodium and chloride reabsorption and extracellular fluid volume. Hypokalemia and/or hypocalcemia occur rarely. Diuresis may occur following glucocorticoid administration.

Skin: Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended and alopecia may occur.

Pharmacokinetics

In humans, hydrocortisone is readily absorbed after oral administration. Hydrocortisone sodium succinate is administered parenterally, and absorption is rapid after IM administration.

Contraindications/Precautions/Warnings

Systemic use of glucocorticoids are generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison's), when administered IM in patients with idiopathic thrombocytopenia, and in patients hypersensitive to a particular compound. Use of sustained-release injectable glucocorticoids is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically other than with "burst" therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a "stressor" (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally manifest as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU), may all be seen with short-term "burst" therapy as well as with alternate-day maintenance therapy on days when drug is given. Adverse effects in dogs can include: dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and potentially more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term, high dose therapy can lead to "Cushingoid" effects.

Reproductive/Nursing Safety

Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreatic, and mammary development. Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns.

Overdosage/Acute Toxicity

Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydrocortisone and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Administered concomitantly with glucocorticoids may cause hypokalemia; in humans, there have been cases of CHF and cardiac enlargement reported after using hydrocortisone to treat Amphotericin B adverse effects
- **ANTICHOLINESTERASE AGENTS** (e.g., **pyridostigmine**, **neostigmine**, etc.): In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration
- **ASPIRIN:** Glucocorticoids may reduce salicylate blood levels
- **BARBITURATES:** May increase the metabolism of glucocorticoids and decrease flumethasone blood levels
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required
- **CYCLOSPORINE:** Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear
- **DIURETICS, POTASSIUM-DEPLETING** (e.g., **spironolactone**, **triamterene**): Administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE:** May reduce hydrocortisone blood levels
- **ESTROGENS:** The effects of hydrocortisone and, possibly, other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN:** Insulin requirements may increase in patients receiving glucocorticoids
- **KETOCONAZOLE and other AZOLE ANTIFUNGALS:** May decrease the metabolism of glucocorticoids and increase hydrocortisone blood levels; ketoconazole may induce adrenal insufficiency when glucocorticoids are withdrawn by inhibiting adrenal corticosteroid synthesis
- **MACROLIDE ANTIBIOTICS** (**erythromycin**, **clarithromycin**): May decrease the metabolism of glucocorticoids and increase hydrocortisone blood levels
- **MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDs:** Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration
- **PHENOBARBITAL:** May increase the metabolism of glucocorticoids and decrease hydrocortisone blood levels
- **RIFAMPIN:** May increase the metabolism of glucocorticoids and decrease hydrocortisone blood levels
- **VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoids
- **WARFARIN:** Hydrocortisone may affect INR's; monitor

Laboratory Considerations

- Glucocorticoids may increase **serum cholesterol**
- Glucocorticoids may increase **urine glucose** levels
- Glucocorticoids may decrease **serum potassium**

- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce T_3 & T_4 values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of I^{131} by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids
- False-negative results of the **nitroblue tetrazolium** test for systemic bacterial infections may be induced by glucocorticoids
- Glucocorticoids may cause **neutrophilia** within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation
- Glucocorticoids can cause **lymphopenia** which can persist for weeks after drug discontinuation in dogs

Doses

■ DOGS:

For adjunctive therapy for adrenocortical insufficiency:

- a) For acute hypoadrenocortical crisis: Hydrocortisone sodium succinate/phosphate 0.5–0.625 mg/kg/hr as an IV infusion. (Mooney 2003)
- b) For glucocorticoid “coverage” in animals that have iatrogenic secondary adrenocortical insufficiency and/or HPA suppression: Animals exhibiting mild to moderate signs of glucocorticoid deficiency: 0.2–0.5 mg/kg PO every day.

For animals with HPA suppression undergoing a “stress” factor: Hydrocortisone sodium succinate 4–5 mg/kg just before and after stressful events (e.g., major surgery). Continue with lower dosages until at least 3rd post-operative day. Access to a water-soluble form of glucocorticoid should be available should animal “collapse.” (Kemppainen 1986)

- c) For adrenalectomy in patients with hyperadrenocorticism: Soluble salt of hydrocortisone 4–5 mg/kg IV either 1 hour prior to surgery or at the time of anesthesia induction. May also be added to IV fluids and infused during surgery. Repeat dosage at end of procedure; may give IM or IV. Glucocorticoid supplementation must be maintained using an oral product (initially prednisolone 0.5 mg/kg twice daily, cortisone acetate 2.5 mg/kg twice daily, or dexamethasone 0.1 mg/kg once daily). Slowly taper to maintenance levels (prednisolone 0.2 mg/kg once a day, or cortisone acetate 0.5 mg/kg twice daily) over 7–10 days. Should complications develop during the taper, reinstate doses at 5 times the maintenance dose. Most dogs can stop exogenous steroid therapy in about 2 months (based on an ACTH stimulation test). (Peterson 1986)

For adjunctive therapy of septic shock:

- a) 0.08 mg/kg/hr IV. Low-dose hydrocortisone infusions can reduce the time that vasopressors are required and lead to earlier resolution of sepsis-induced organ dysfunction. (Crowe 2002)

For glucocorticoid (antiinflammatory) activity:

- a) 5 mg/kg PO every 12 hours; 5 mg/kg (salt not specified) IV or IM once daily (Jenkins 1985)
- b) 4.4 mg/kg PO q12h (Kirk 1989)

■ CATS:

For glucocorticoid (antiinflammatory) activity:

- a) 5 mg/kg PO, IV or IM every 12 hours (Davis 1985)
- b) 4.4 mg/kg PO q12h (Kirk 1989)

For adjunctive therapy of septic shock:

- a) 0.08 mg/kg/hr IV. Low-dose hydrocortisone infusions can reduce the time that vasopressors are required and lead to earlier resolution of sepsis-induced organ dysfunction. (Crowe 2002)

■ CATTLE:

For adjunctive treatment of photosensitization reactions:

- a) 100–600 mg (salt not specified) in 1000 mL of 10% dextrose saline IV or SC. (Black 1986)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

As a glucocorticoid:

- a) Hydrocortisone sodium succinate: 1–4 mg/kg as an IV infusion (Robinson 1987)

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

Client Information

- Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting with the veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects become severe or progress.

Chemistry/Synonyms

Also known as compound F or cortisol, hydrocortisone is secreted by the adrenal gland. Hydrocortisone occurs as an odorless, white to practically white, crystalline powder. It is very slightly soluble in water and sparingly soluble in alcohol. Hydrocortisone is administered orally.

Hydrocortisone sodium succinate occurs as an odorless, white to nearly white, hygroscopic, amorphous solid. It is very soluble in both water and alcohol. Hydrocortisone sodium succinate injection is administered via IM or IV routes.

Hydrocortisone may also be known as: antiinflammatory hormone, compound F, cortisol, hydrocortisonum, 17-hydroxycorticosterone, and NSC-10483; many trade names are available.

Storage/Stability/Compatibility

Hydrocortisone tablets should be stored in well-closed containers. The cypionate oral suspension should be stored in tight, light resistant containers. All products should be stored at room temperature (15–30°C); avoid freezing the suspensions or solutions. After reconstituting solutions, only use products that are clear. Discard unused solutions after 3 days.

Hydrocortisone sodium succinate is reportedly physically **compatible** with the following solutions and drugs: dextrose-Ringer's injection combinations, dextrose-Ringer's lactate injection combinations, dextrose-saline combinations, dextrose injections, Ringer's injection, lactated Ringer's injection, sodium chloride injections, amikacin sulfate, aminophylline, amphotericin B (limited quantities), calcium chloride/gluconate, cephalothin sodium (not in combination with aminophylline), cephalirin sodium, chloramphenicol sodium succinate, clindamycin phosphate, corticotropin, daunorubicin HCl, dopamine HCl, erythromycin gluceptate, erythromycin lactobionate, lidocaine HCl, mephentermine sulfate, metronidazole with sodium bicarbonate, netilmicin sodium, penicillin G potassium/sodium, piperacillin sodium, polymyxin B sulfate, potassium chloride, prochlorperazine edisylate, sodium bicarbonate, thiopental sodium, vancomycin HCl, verapamil HCl, and vitamin B-complex with C.

Hydrocortisone sodium succinate is reportedly physically **incompatible** when mixed with the following solutions and drugs: ampicillin sodium, bleomycin sulfate, colistimethate sodium, dimenhydrinate, diphenhydramine HCl, doxorubicin HCl, ephedrine sulfate, heparin sodium, hydralazine HCl, metaraminol bitartrate, methicillin sodium, nafcillin sodium, oxytetracycline HCl, pentobarbital sodium, phenobarbital sodium, promethazine HCl, secobarbital sodium, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Hydrocortisone sodium succinate is reportedly physically **incompatible** when mixed with the following solutions and drugs: ampicillin sodium, bleomycin sulfate, colistimethate sodium, dimenhydrinate, diphenhydramine HCl, doxorubicin HCl, ephedrine sulfate, heparin sodium, hydralazine HCl, metaraminol bitartrate, methicillin sodium, nafcillin sodium, oxytetracycline HCl, pentobarbital sodium, phenobarbital sodium, promethazine HCl, secobarbital sodium, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

There are no products containing hydrocortisone (or its salts) known for systemic use. There are a variety of hydrocortisone veterinary products for topical use. A 10 ppb tolerance has been established for hydrocortisone (as the succinate or acetate) in milk.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Hydrocortisone Tablets: 5 mg, 10 mg, 20 mg; *Cortef*® (Upjohn); generic; (Rx)

Hydrocortisone Sodium Succinate Injection: 100 mg/vial, 250 mg/vial, 500 mg/vial, 1000 mg/vial (as sodium succinate) in 2 mL, 4 mL and 8 mL *Univials*, flitop vials, *Act-O-Vials* and vials; *Solu-Cortef*® (Upjohn); *A-Hydrocort*® (Abbott); (Rx)

There are many OTC and Rx topical and anorectal products available in a variety of dosage forms.

HYDROGEN PEROXIDE 3% (ORAL)

(*hye-droe-jen per-oks-ide*)

ORAL EMETIC, TOPICAL ANTISEPTIC

Also see the Decontamination information in the appendix

Prescriber Highlights

- Topical antiseptic that is used orally as an emetic in dogs & sometimes cats particularly when clients cannot transport the patient to a veterinary hospital in a timely manner
- Many contraindications to use (for emesis)

Uses/Indications

Hydrogen peroxide 3% solution can be used as an orally administered emetic in dogs and cats. It is best reserved for those cases when animals cannot be transported to a veterinary hospital in a timely way and immediate emesis is required. Apomorphine for dogs and cats (apomorphine is somewhat controversial for cats), or xylazine for cats are generally preferred emetic agents to be administered in a veterinary practice.

Pharmacology/Actions

Orally administered hydrogen peroxide solution (3%) induces a vomiting reflex via direct irritant effects of the oropharynx and gastric lining. After administering PO to dogs or cats, emesis usually ensues within 10 minutes.

Pharmacokinetics

No pharmacokinetic information located.

Contraindications/Precautions/Warnings

Do not induce emesis in those dogs or cats that are already vomiting, severely lethargic, comatose, debilitated (e.g., respiratory distress, decreased swallowing reflex, bradycardia, etc.), seizing or hyperactive, have had recent abdominal surgery or with megaesophagus. Emesis is generally contraindicated after ingestions of corrosives/caustics (e.g., acids, alkalis), sharp objects, or bagged illicit drugs. Emesis is usually contraindicated after ingestion of a hydrocarbon or petroleum distillate.

Use caution when attempting to induce emesis in a dog that has ingested a compound that can cause seizures or CNS depression as CNS status may rapidly deteriorate.

Before inducing emesis, obtain a complete history of the ingestion and ensure that vital signs are stable.

Administration and emesis generally must occur within 4 hours (some say 2 hours or 6 hours maximum) of the toxic ingestion.

Do not use emetics in rodents or rabbits.

If home administration of hydrogen peroxide is necessary, be sure that clients use only the 3% medical grade solution and not another more concentrated hydrogen peroxide product.

Because aspiration and/or bradycardia are possible, animals should be closely observed after administration. Suctioning, respiratory and cardiovascular support (e.g., atropine) should be available. Do not allow animal to re-ingest vomitus.

Successful induction of emesis does not ensure that stomach contents have been emptied and significant quantities of the ingested drug/toxin may remain or already been absorbed.

Adverse Effects

Aspiration of hydrogen peroxide solution during administration or stomach contents after inducing emesis is possible. Inducing emesis in animals with cardiovascular compromise may cause a vasovagal (bradycardic) response. Gastric ulceration in cats and gastric-dilatation-volvulus in dogs have been reported.

Reproductive/Nursing Safety

No specific information was located. While orally administered 3% hydrogen peroxide is unlikely to cause reproductive harm, weigh the risks to the dam and offspring of the ingested toxin versus the risks associated with inducing emesis.

Overdosage/Acute Toxicity

Hydrogen peroxide 3% solution is relatively non-toxic (see Adverse Effects) after oral ingestion. Hydrogen peroxide in concentrations of 10% or greater can be very corrosive (severe burns to oral/gastric mucosa) and induce oxygent emboli after oral ingestion.

Drug Interactions

■ **ACETYLCYSTEINE (oral):** Hydrogen peroxide can oxidize acetylcysteine in the gut and although clinical significance is unclear, alternative emetics (e.g., apomorphine, xylazine) are preferred for acetaminophen overdoses

■ **ANTIEMETICS (e.g., ondansetron, maropitant, etc.):** Preadministration or ingestion of these products may negate the emetic effects of hydrogen peroxide

Laboratory Considerations

No specific concerns were noted.

Doses

■ DOGS/CATS:

As an emetic:

- 1–2 mL/kg PO up to 2–3 times (Rudloff 2006b)
- 1–5 mL/kg PO; generally not to exceed 50 mL for dogs and 10 mL for cats; may repeat one time if after 10 minutes emesis does not occur. Inducing emesis is most effective if administered after a small meal. (Peterson 2006c)
- 0.25–0.5 mL/kg PO; may repeat once after 5–15 minutes if vomiting has not occurred. (Cote 2005)

Monitoring

- Efficacy (emesis, signs associated with toxicity of the substance ingested, blood levels of toxicants if applicable)
- Heart rate/respiration rate & auscultation after emesis

Client Information

- Use only under the direct instructions of a veterinarian or a poison control center
- Only use hydrogen peroxide 3%; stronger concentrations can be very toxic
- Carefully administer; do not allow patient to “inhale” the liquid
- Observe animal after administration, do not allow them to re-ingest the vomited material (vomit)
- Save all vomitus for the veterinarian to examine

Chemistry/Synonyms

Hydrogen peroxide 3% solution is a clear, colorless liquid containing 2.5–3.5% w/v hydrogen peroxide. Up to 0.05% of the liquid may contain preservatives.

Hydrogen peroxide 3% solution may also be known as dilute hydrogen peroxide solution, hydrogen peroxide solution 10-volume (**Note:** NOT 10%), or hydrogen peroxide topical solution.

Storage/Stability

Store 3% solutions in airtight containers at room temperature and protected from light.

Hydrogen peroxide 3% can deteriorate with time; outdated or improperly stored products may not be effective as an emetic.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None as an oral emetic

HUMAN-LABELED PRODUCTS:

None as an oral emetic. Hydrogen Peroxide 3% Solution is readily available over-the-counter from a variety of manufacturers. It is usually sold in pint bottles.

HYDROMORPHONE

(hye-droe-mor-fone) Dilaudid®

OPIATE AGONIST

Prescriber Highlights

- ▶ **Injectable opiate sedative/restraining agent, analgesic, & preanesthetic similar to oxymorphone**
- ▶ **Less expensive than oxymorphone on a per mL basis, but has shorter duration of action**
- ▶ **Contraindications:** Hypersensitivity to it, diarrhea caused by a toxic ingestion, prior to GI obstructive surgery (may cause vomiting)
- ▶ **Extreme caution:** Respiratory disease or acute respiratory dysfunction
- ▶ **Caution:** Hypothyroidism, severe renal insufficiency (acute uremia), adrenocortical insufficiency, geriatric or severely debilitated patients, head injuries or increased intracranial pressure & acute abdominal conditions (e.g., colic)
- ▶ **Adverse Effects:** CNS depression, respiratory depression, & bradycardia; decreased GI motility with resultant constipation possible
- ▶ **CATS:** Ataxia, hyperesthesia, hyperthermia, & behavioral changes (without concomitant tranquilization)
- ▶ **Drug-drug; drug-lab interactions**
- ▶ **C-II controlled substance**

Uses/Indications

Like oxymorphone, hydromorphone is used in dogs and cats as a sedative/restraining agent, analgesic and preanesthetic. It may also be useful in other species, but little data or experience is available. Because of expense and availability issues with oxymorphone, hydromorphone is rapidly replacing it in veterinary medicine. In dogs and cats, hydromorphone is generally less sedating than morphine, usually causes minimal histamine release after IV administration, and rarely causes vasodilation and hypotension.

Pharmacology/Actions

Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle.

The morphine-like agonists (morphine, meperidine, oxymorphone, hydromorphone) have primary activity at the μ receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include: CNS: euphoria, sedation, and confusion. Cardiovascular: bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. Urinary: Increased bladder sphincter tone can induce urinary retention.

Various species may exhibit contradictory effects from these agents. For example, horses, cattle, swine, and cats may develop excitement and dogs may defecate after morphine injections. These effects are in contrast to the expected effects of sedation and consti-

pation. Dogs and humans may develop miosis, while other species (especially cats) may develop mydriasis.

Hydromorphone is approximately 5 times more potent an analgesic on a per weight basis when compared to morphine and approximately equal in potency to oxymorphone. At the usual doses employed, hydromorphone alone has good sedative qualities in the dog. Respiratory depression can occur especially in debilitated, neonatal, or geriatric patients. Bradycardia, as well as a slight decrease in cardiac contractility and blood pressure, may be seen. Like oxymorphone, hydromorphone does initially increase the respiratory rate (panting in dogs) while actual oxygenation may be decreased and blood CO₂ levels may increase by 10 mmHg or more. Gut motility is decreased with resultant increases in stomach emptying times. Unlike either morphine or meperidine, hydromorphone may only infrequently cause mild histamine release in dogs or cats after IV injection.

Pharmacokinetics

Hydromorphone is absorbed when given by IV, IM, SC, and rectal routes. The onset of analgesic efficacy occurs within 15–30 minutes, depending on route of administration.

The drug is metabolized in the liver, primarily by glucuronidation. Because cats are deficient in this metabolic pathway, half-lives in cats are probably prolonged. The glucuronidated metabolite is excreted by the kidney.

Contraindications/Precautions/Warnings

All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), and geriatric or severely debilitated patients. Hydromorphone is contraindicated in patients hypersensitive to narcotic analgesics, and those with diarrhea caused by a toxic ingestion (until the toxin is eliminated from the GI tract). All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), and geriatric or severely debilitated patients.

Because it may cause vomiting, hydromorphone use should be considered contraindicated as a preanesthetic med in animals with suspected gastric dilation, volvulus, or intestinal obstruction.

Hydromorphone should be used with extreme caution in patients with head injuries, increased intracranial pressure, and acute abdominal conditions (e.g., colic) as it may obscure the diagnosis or clinical course of these conditions. It should be used with extreme caution in patients suffering from respiratory disease or acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation).

Hydromorphone can cause bradycardia and therefore should be used cautiously in patients with preexisting bradyarrhythmias.

Neonatal, debilitated, or geriatric patients may be more susceptible to the effects of hydromorphone and may require lower dosages. Patients with severe hepatic disease may have prolonged duration of action of the drug. If used in cats at high dosages, the drug has been recommended to be given along with a tranquilizing agent, as hydromorphone can produce bizarre behavioral changes in this species. This also is true in cats for the other opiate agents, such as morphine.

Opiate analgesics are contraindicated in patients who have been stung by the scorpion species *Centruroides sculpturatus* Ewing and *C. gertschi* Stahnke as it may potentiate these venoms.

Adverse Effects

Hydromorphone has a similar adverse effect profile to oxymorphone or morphine in dogs and cats. CNS depression may be greater than desired, particularly when treating moderate to severe pain. Dose related respiratory depression is possible, and more

likely during general anesthesia. Panting (may occur more often than with oxymorphone) and cough suppression (may be of benefit) may occur. Cats may be prone to developing hyperthermia. Secondary to enhanced vagal tone, hydromorphone can cause bradycardia. This apparently occurs on par with morphine or oxymorphone. Hydromorphone may cause histamine release which, while generally clinically insignificant, may be significant in critically ill animals. Vomiting and defecation can occur after dosing; use caution when using as a preanesthetic. Constipation is possible with chronic dosing.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Most opiates are excreted into milk, but effects on nursing offspring may not be significant.

Overdosage/Acute Toxicity

Massive overdoses may produce profound respiratory and/or CNS depression in most species. Other effects may include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated, and animals should be closely observed as naloxone's effects may diminish before sub-toxic levels of oxymorphone are attained. Mechanical respiratory support should be considered in cases of severe respiratory depression.

In susceptible patients, moderate overdoses may require naloxone and supportive treatment as well.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydromorphone and may be of significance in veterinary patients:

- **BUTORPHANOL, NALBUPHINE:** Potentially could antagonize opiate effects
- **CNS DEPRESSANTS, OTHER:** Additive CNS effects possible
- **DIURETICS:** Opiates may decrease efficacy in CHF patients
- **MONOAMINE OXIDASE INHIBITORS** (e.g., **amitraz** and potentially, **selegiline**): Severe and unpredictable opiate potentiation may be seen; not recommended (in humans) if MAO inhibitor has been used within 14 days
- **MUSCLE RELAXANTS, SKELETAL:** Hydromorphone may enhance effects
- **PHENOTHIAZINES:** Some phenothiazines may antagonize analgesic effects and increase risk for hypotension
- **TRICYCLIC ANTIDEPRESSANTS** (**clomipramine**, **amitriptyline**, etc.): Hydromorphone may exacerbate the effects of tricyclic antidepressants
- **WARFARIN:** Opiates may potentiate anticoagulant activity

Laboratory Considerations

- As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

Doses

■ DOGS:

- a) As an analgesic: 0.05–0.2 mg/kg IM, IV or SC q2–6 hours (Wagner 2002)
- b) For cancer pain: 0.08–0.2 mg/kg IV, IM, or SC (Lester and Gaynor 2000)

- c) For moderate to severe pain: 0.08–0.3+ mg/kg IV, IM or SC q2–6 hours (Mathews 2000)
- d) As an analgesic: 0.05–0.2 mg/kg IV, IM, SC q2–4h (Hansen 2003b), (Hardie 2006)
- e) As an analgesic: 0.2–0.6 mg/kg PO q6–8h; For perioperative pain: 0.1–0.2 mg/kg IV, IM, SC q2–4h (Pascoc 2006)

- f) As a premed prior to moderately painful procedures: 0.1 mg/kg; may be combined with acepromazine (0.02–0.05 mg/kg) in young, healthy patients. As a sedative/restraint agent for fractious or aggressive dogs: 0.1–0.2 mg/kg mixed with acepromazine (0.05 mg/kg) IM. Maximal effect usually reached in about 15 minutes, but an additional wait of another 15 minutes may be necessary in some dogs.

As an alternate induction method (especially in critical patients): hydromorphone 0.05–0.2 mg/kg IV, slowly to effect followed by diazepam 0.02 mg/kg IV (do not mix two drugs together). Endotracheal intubation may be possible after administration, if not, delivery of an inhalant by facemask will give a greater depth of anesthesia. Positive pressure ventilation likely will be necessary. If bradycardia requires treatment, use either glycopyrrolate (0.01–0.02 mg/kg IV) or atropine (0.02–0.04 mg/kg IV). (Pettifer and Dyson 2000)

■ CATS:

- a) As an analgesic: 0.05–0.1 mg/kg IM, IV or SC q2–6 hours (Wagner 2002)
- b) For cancer pain: 0.08–0.2 mg/kg IV, IM, or SC (Lester and Gaynor 2000)
- c) As an analgesic: 0.02–0.05 mg/kg IV, IM, SC q2–4h (Hansen 2003b), (Hardie 2006)
- d) For moderate to severe pain: 0.08–0.3+ mg/kg IV, IM or SC q2–6 hours (Mathews 2000)
- e) As a premed prior to moderately painful procedures: 0.1 mg/kg; may be combined with acepromazine (0.05–0.2 mg/kg) in young, healthy patients.

As an alternate induction method (especially in critical patients): hydromorphone 0.05–0.2 mg/kg IV, slowly to effect followed by diazepam 0.02 mg/kg IV (do not mix two drugs together). Endotracheal intubation may be possible after administration, if not, delivery of an inhalant by facemask will give a greater depth of anesthesia. Positive pressure ventilation likely will be necessary. If bradycardia requires treatment, use either glycopyrrolate (0.01–0.02 mg/kg IV) or atropine (0.02–0.04 mg/kg IV). (Pettifer and Dyson 2000)

■ FERRETS:

- a) As a pre-op: 0.05–0.1 mg/kg IV; as a CRI post-op: 0.05 mg/kg IV loading dose, then 0.05–0.1 mg/kg/hr (Lichtenberger 2006a)

■ SMALL MAMMALS:

- a) Rabbits: 0.05–0.1 mg/kg IV; as a CRI post-op: 0.05 mg/kg IV loading dose, then 0.05–0.1 mg/kg/hr (Lichtenberger 2006a)

Monitoring

- Respiratory rate/depth (pulse oximetry highly recommended)
- CNS level of depression/excitation
- Blood pressure (especially with IV use)
- Cardiac rate
- Analgesic efficacy

Client Information

- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision

Chemistry/Synonyms

A semi-synthetic phenanthrene-derivative opiate related to morphine, hydromorphone HCl occurs as white, fine, crystalline powder. It is freely soluble in water. The commercial injection has a pH of 4–5.5.

Hydromorphone may also be known as: dihydromorphinone hydrochloride, *Dolonovag*®, *Hydal*®, *HydroStat IR*®, *Hydromorph*®, *Opidol*®, *Palladon*®, *Palladone*®, and *Sophidone*®.

Storage/Stability/Compatibility

The injection should be stored at room temperature and protected from light. A slight yellowish tint to the solution may occur, but does not indicate loss of potency. The injection remains stable for at least 24 hours when mixed with commonly used IV fluids if protected from light.

Hydromorphone tablets should be stored at room temperature in tight, light resistant containers. The suppositories should be kept in the refrigerator.

Hydromorphone injection is **compatible** in commonly used IV fluids (for 24 hours when protected from light at 25°C) and with midazolam, ondansetron, potassium chloride, and heparin sodium. Hydromorphone injection mixed in the same syringe with atropine and medetomidine (*Domitor*®) for use as a preop in dogs prior to sevoflurane or propofol anesthesia has been described (Ko 2005). Hydromorphone is **incompatible** with sodium bicarbonate, or thiopental.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Hydromorphone HCl Injection: 1 mg/mL in 1 mL amps & syringes, 2 mg/mL in 1 mL amps, 1 mL syringes, 1 mL amps and 20 mL vials & multidose vials; 4 mg/mL in 1 mL amps & syringes; and 10 mg/mL in 1 mL, 5 mL, single-dose vials & amps and 50 mL single-dose vials; *Dilaudid*® and *Dilaudid-HP*® (Abbott); generic; (Rx, C-II)

Hydromorphone HCl Powder for Injection, lyophilized: 250 mg (10 mg/mL after reconstitution) in single-dose vials; *Dilaudid-HP*® (Abbott); (Rx, C-II)

Hydromorphone HCl Tablets: 2 mg, 4 mg, and 8 mg; *Dilaudid*® (Abbott); generic; (Rx, C-II)

Hydromorphone HCl Capsules (extended-release): 12 mg, 16 mg, 24 mg, & 32 mg; *Palladone*® (Purdue Pharma); (Rx, C-II)

Hydromorphone HCl Oral Solution: 1 mg/1 mL in 4 mL UD and 8 mL UD patient cups; 250 mL & 473 mL; *Dilaudid-5*® (Abbott); generic; (Rx, C-II)

Hydromorphone Suppositories: 3 mg; Hydromorphone HCl (Padlock); *Dilaudid*® (Abbott); (Rx, C-II)

Hydroxyethyl Starch — See Hetastarch

HYDROXYUREA

(hye-drox-ee-yor-ee-a) Hydrea®, Droxia®, Mylocel®

ANTINEOPLASTIC**Prescriber Highlights**

- Antineoplastic used for treatment of polycythemia vera, mastocytomas, & leukemias in dogs & cats
- Caution: Anemia, bone marrow depression, history of urate stones, infection, impaired renal function, or in patients who have received previous chemotherapy or radiotherapy
- Adverse Effects: GI effects, stomatitis, sloughing of nails, alopecia, & dysuria; most serious are bone marrow depression & pulmonary fibrosis
- Proven teratogen

Uses/Indications

Hydroxyurea may be useful in the treatment of polycythemia vera, mastocytomas, and leukemias in dogs and cats. It is often used to treat dogs with chronic myelogenous leukemia no longer responsive to busulfan. Hydroxyurea, potentially, may be of benefit in the treatment of feline hypereosinophilic syndrome and in the adjunctive treatment of canine meningiomas. It can also be used in dogs for the adjunctive medical treatment (to reduce hematocrit) of right to left shunting patent ductus arteriosus or tetralogy of Fallot.

Pharmacology/Actions

While the exact mechanism of action for hydroxyurea has not been determined, it appears to interfere with DNA synthesis without interfering with RNA or protein synthesis. Hydroxyurea apparently inhibits thymidine incorporation into DNA and may directly damage DNA. It is an S-phase inhibitor, but may also arrest cells at the G₁-S border.

Hydroxyurea inhibits urease, but is less potent than acetohydroxamic acid. Hydroxyurea can stimulate production of fetal hemoglobin.

Pharmacokinetics

Hydroxyurea is well absorbed after oral administration and crosses the blood-brain barrier. Approximately 50% of an absorbed dose is excreted unchanged in the urine and about 50% is metabolized in the liver and then excreted in the urine.

Contraindications/Precautions/Warnings

Risk versus benefit should be considered before using hydroxyurea in patients with the following conditions: anemia, bone marrow depression, history of urate stones, current infection, impaired renal function, or in patients who have received previous chemotherapy or radiotherapy.

Adverse Effects

Potential adverse effects include GI effects (anorexia, vomiting, diarrhea), stomatitis, sloughing of nails, alopecia, and dysuria. The most serious adverse effects associated with hydroxyurea are bone marrow depression (anemia, thrombocytopenia, leukopenia) and pulmonary fibrosis. If myelotoxicity occurs, it is recommended to halt therapy until values return to normal. Methemoglobinemia has been reported in cats given high dosages (>500 mg).

Reproductive/Nursing Safety

Hydroxyurea is a teratogen. Use only during pregnancy when the benefits to the mother outweigh the risks to the offspring. Hydroxyurea can suppress gonadal function; arrest of spermatogenesis has been noted in dogs. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Although hydroxyurea distribution into milk has not been documented, nursing puppies or kittens should receive milk replacer when the dam is receiving hydroxyurea.

Overdosage/Acute Toxicity

Cats given hydroxyurea in doses greater than 500 mg (total) may develop methemoglobinemia. Because of the potential toxicity of the drug, overdoses should be treated aggressively with gut emptying protocols employed when possible. For further information, refer to an animal poison control center.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydroxyurea and may be of significance in veterinary patients:

- **BONE MARROW DEPRESSANT DRUGS, OTHER** (e.g., other antineoplastic, chloramphenicol, flucytosine, amphotericin B, or colchicine): Other bone marrow depressant drugs may cause additive myelosuppression when used with hydroxyurea

Laboratory Considerations

- Hydroxyurea may raise serum **uric acid** levels; drugs such as allopurinol may be required to control hyperuricemia

Doses

For more information on using hydroxyurea as part of chemotherapy protocols, refer to the protocols found in the appendix or other dosages/protocols found in numerous references, including: *Withrow and MacEwen's Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

■ DOGS:

For polycythemia vera; chronic myelogenous leukemia:

- a) 50 mg/kg 3 times per week (Jacobs, Lumsden et al. 1992)

For polycythemia vera:

- a) Initially at 20–25 mg/kg PO twice daily; once the hematocrit is below 60% give every other day. (Vail and Thamm 2005)
- b) 30 mg/kg once daily for one week, then 15 mg/kg once daily until remission; then taper to lowest effective frequency by monitoring hematocrit (Raskin 1994)
- c) 50–80 mg/kg PO every 3 days (Kitchell and Dhaliwal 2000)

For chronic myelogenous leukemia:

- a) 50 mg/kg PO q24h for 1–2 weeks, then every other day (Couto 2003)

■ CATS:

For polycythemia vera; chronic myelogenous leukemia:

- a) 25 mg/kg 3 times per week (Jacobs, Lumsden et al. 1992)

For polycythemia vera:

- a) Initially at 10–15 mg/kg PO twice daily; once the hematocrit is below 60% give every other day. (Vail and Thamm 2005)

- b) 30 mg/kg once daily for one week, then 15 mg/kg once daily until remission; then taper to lowest effective frequency by monitoring hematocrit. Cats must be monitored more frequently than dogs as they have a greater risk of developing bone marrow toxicity. (Raskin 1994)

Monitoring

- CBC with platelets at least every 1–2 weeks until stable; then every 3 months
- BUN/Serum Creatinine; initially before starting treatment and then every 3–4 months

Chemistry/Synonyms

Structurally similar to urea and acetohydroxamic acid, hydroxyurea occurs as white, crystalline powder that is freely soluble in water. It is moisture labile.

Hydroxyurea may also be known as: hydroxycarbamide, hydroxycarbamidum, NSC-32065, SQ-1089, WR-83799, *Dacrodil*®, *Droxiurea*®, *Hydrea*®, *Droxia*®, *Hydrine*®, *Litalir*®, *Medroxyurea*®, *Neodrea*®, *Onco-Carbide*®, *Oxeron*®, and *Syrea*®.

Storage/Stability

Capsules should be stored in tight containers at room temperature. Avoid excessive heat.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Hydroxyurea Capsules: 200 mg, 300 mg, 400 mg and 500 mg; *Hydrea*® (Bristol-Myers Squibb); *Droxia*® (Bristol-Myers Squibb Oncology); generic; (Rx)

HYDROXYZINE HCL HYDROXYZINE PAMOATE

(hye-drox-i-zeen) Atarax®, Vistaril®

ANTIHISTAMINE

Prescriber Highlights

- Used principally for antihistaminic, antipruritic, & sedative/tranquilization qualities, often in atopic patients
- Contraindications: Hypersensitivity to the drug
- Caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyeloduodenal obstruction
- Adverse Effects: Sedation most likely; DOGS (rarely): Tremors, seizures; CATS: Polydipsia, depression, or behavioral changes.

Uses/Indications

Hydroxyzine is used principally for its antihistaminic, antipruritic, and sedative/tranquilization qualities, often in atopic patients.

Pharmacology/Actions

Like other H₁-receptor antihistamines, hydroxyzine acts by competing with histamine for sites on H₁-receptor sites on effector cells. Antihistamines do not block histamine release, but can antagonize its effects. In addition to its antihistaminic effects, hydroxyzine pos-

sesses anticholinergic, sedative, tranquilizing, antispasmodic, local anesthetic, mild bronchodilative, and antiemetic activities.

Pharmacokinetics

Hydroxyzine is rapidly and well absorbed after oral administration. Effects generally persist for 6–8 hours in dogs and up to 12 hours in cats. Hydroxyzine is apparently metabolized in liver.

Contraindications/Precautions/Warnings

Hydroxyzine is contraindicated in patients hypersensitive to it. It should be used with caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyloduodenal obstruction.

Adverse Effects

The most likely adverse effect associated with hydroxyzine is sedation. In dogs, this is usually mild and transient. Occasionally antihistamines can cause a hyperexcitability reaction. Dogs have reportedly developed fine rapid tremors, whole body tremors and, rarely, seizures while receiving this drug. Cats may develop polydipsia, depression, or behavioral changes while on this medication.

Reproductive/Nursing Safety

At doses substantially greater than those used therapeutically, hydroxyzine has been shown to be teratogenic in lab animals. Use during pregnancy (particularly during the first trimester) only when the benefits outweigh the risks. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is unknown if hydroxyzine enters maternal milk; cetirizine a metabolite of hydroxyzine, has been detected in milk.

Overdosage/Acute Toxicity

There is limited information available. There are no specific antidotes available. Overdoses would be expected to cause increased sedation and perhaps, hypotension. Gut emptying protocols should be considered with large or unknown quantity overdoses. Supportive and symptomatic treatment is recommended if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hydroxyzine and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS:** Additive anticholinergic effects may occur when hydroxyzine is used concomitantly with other anticholinergic agents
- **CNS DEPRESSANT DRUGS, OTHER:** Additive CNS depression may be seen if combining hydroxyzine with other CNS depressant medications, such as barbiturates, tranquilizers, etc
- **EPINEPHRINE:** Hydroxyzine may inhibit or reverse the vasopressor effects of epinephrine; use norepinephrine or metaraminol instead

Laboratory Considerations

- False increases have been reported in **17-hydroxycorticosteroid** urine values after hydroxyzine use
- Because antihistamines can decrease the wheal and flair response to skin **allergen testing**, antihistamines should be discontinued from 3–7 days (depending on the antihistamine used and the reference) before intradermal skin tests

Doses

■ DOGS:

As an antipruritic/antihistamine:

- a) 2.2 mg/kg PO three times daily (q8h) (Gershwin 1992), (Paradis and Scott 1992), (White 2007)
- b) For flea allergy dermatitis: 2 mg/kg q8h PO (Griffen 1994)

■ CATS:

As an antipruritic/antihistamine:

- a) For pruritus: 1–2 mg/kg or 5–10 mg/cat PO q8–12h (Messinger 2000)
- b) For pruritus: 5–10 mg (total dose) or 2.2 mg/kg PO q8–12h (Hnilica 2003c)

For frequently recurrent idiopathic lower urinary tract disease:

- a) 5–10 mg (total dose) per cat PO q12h (Lane 2002a)

■ FERRETS:

- a) 2 mg/kg PO 3 times daily (Williams 2000)

■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

- a) 0.5–1 mg/kg IM or PO twice daily (Robinson 1992)
- b) Using the pamoate salt: 0.67 mg/kg PO twice daily (Duran 1992)

■ BIRDS:

For pruritus associated with allergies, feather picking, or self-mutilation:

- a) 2 mg/kg q8h PO or 1.5–2 mg per 4 oz of drinking water daily; adjust dose to minimize drowsiness and maximize effect (Hillyer 1994)
- b) 2 mg/kg PO q12h (Siebert 2003b)

Monitoring

- Efficacy
- Adverse effects

Client Information

- May cause drowsiness and impede working dogs' abilities

Chemistry/Synonyms

A piperazine-derivative antihistamine, hydroxyzine HCl occurs as a white, odorless powder. It is very soluble in water and freely soluble in alcohol. Hydroxyzine pamoate occurs as a light yellow, practically odorless powder. It is practically insoluble in water or alcohol.

Hydroxyzine may also be known as: hydroxyzine embonate, hydroxyzine pamoate, hydroxyzine HCl, hydroxyzini HCl, *Vistaril*®, *Atarax*® or *Masmoran*®.

Storage/Stability/Compatibility

Hydroxyzine oral products should be stored at room temperature in tight, light-resistant containers. Avoid freezing all liquid products.

The HCl injection has been reported to be physically **compatible** with the following drugs when mixed in syringes: atropine sulfate, benzquinamide HCl, butorphanol tartrate, chlorpromazine HCl, cimetidine HCl, codeine phosphate, diphenhydramine HCl, doxapram HCl, droperidol, fentanyl citrate, glycopyrrolate, hydromorphone HCl, lidocaine HCl, meperidine HCl, methotrimeprazine, metoclopramide HCl, midazolam HCl, morphine sulfate, oxymorphone HCl, pentazocine lactate, procaine HCl, prochlorperazine edisylate, promazine HCl, promethazine HCl, and scopolamine HBr. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Hydroxyzine HCl Oral Tablets: 10 mg, 25 mg, & 50 mg; generic; (Rx)

Hydroxyzine HCl Oral Solution: 10 mg/5 mL in 16 mL, 118 mL, 120 mL and 473 mL, gal and UD 5, 12.5 and 25 mL; *Atarax*® (Roerig); (Rx); generic; (Rx)

Hydroxyzine HCl Injection: 25 mg/mL in 1 mL and 2 mL vials; 50 mg/mL in 1 mL, 2 mL and 10 mL vials; generic; (Rx)

Hydroxyzine Pamoate Capsules (equivalent to hydroxyzine HCl): 50 mg, & 100 mg; *Vistaril*® (Pfizer); generic; (Rx)

Hydroxyzine Pamoate Suspension (equivalent to hydroxyzine HCl): 25 mg/5 mL (as pamoate) in 120 mL & 473 mL; *Vistaril*® (Pfizer); (Rx)

HYOSCYAMINE SULFATE

(hye-oh-sye-ah-meen or hye-ah-ska-meen) Levsin®

ORAL AND INJECTABLE ANTICHOLINERGIC

Prescriber Highlights

- ▶ Anticholinergic that may be useful for treating hypermotile GI conditions such as irritable bowel syndrome or bradycardia in dogs
- ▶ Limited use in veterinary medicine
- ▶ Adverse effects can include mydriasis, xerostomia, constipation, urinary retention, & xerophthalmia

Uses/Indications

Although not commonly used in veterinary medicine, hyoscyamine may be useful as an alternative to other anticholinergic drugs such as glycopyrrolate for treating bradycardia or hypermotile GI conditions such as irritable bowel syndrome in dogs. It, potentially, could be useful for treating hypersalivation, urinary spasms, vomiting, or reducing secretions peri-operatively, but little is known regarding safety and efficacy in animals when used for these conditions.

In humans, hyoscyamine is used primarily for its effects in reducing GI tract motility or to decrease pharyngeal, bronchial and tracheal secretions.

Pharmacology/Actions

Hyoscyamine is an anticholinergic agent similar to atropine, but more potent both in central and peripheral effects. It inhibits acetylcholine at tissues innervated by postganglionic nerves and smooth muscles that respond to acetylcholine but do not have cholinergic innervation. It does not have action on autonomic ganglia. Pharmacologic effects include dose-related reductions in secretions, gastrointestinal and urinary tract motility, mydriasis, and increased heart rate.

Pharmacokinetics

No pharmacokinetic data was located for veterinary species. In humans, hyoscyamine is rapidly and nearly completely absorbed after oral or sublingual administration. Extended release oral dos-

age forms may have somewhat reduced oral bioavailability. It is distributed throughout the body, enters the CNS and crosses the placenta. Hyoscyamine is partially hydrolyzed in the liver to tropic acid and tropine. The majority of the drug is excreted unchanged in the urine. Elimination half-life is about 3.5 hours; about 7 hours for the sustained-release product, *Levsinex*®. Average duration of action in humans is approximately 4–6 hours.

Contraindications/Precautions/Warnings

Hyoscyamine is contraindicated in patients hypersensitive to it. Patients sensitive to one belladonna alkaloid or derivative may be sensitive to another.

Use with caution in patients with renal dysfunction as hyoscyamine elimination may be reduced. Use of anticholinergics should be carefully considered in patients with tachyarrhythmias, cardiac valve disease or congestive heart failure. Patients with myasthenia gravis may have their condition aggravated with concurrent use of hyoscyamine. Other contraindications for using hyoscyamine in humans include: glaucoma (narrow or wide angle), intestinal obstruction, toxic megacolon, intestinal atony, severe ulcerative colitis, obstructive uropathy, or acute hemorrhage.

Adverse Effects

Adverse effects can include mydriasis, xerostomia, constipation, urinary retention, and xerophthalmia. Higher dosages may cause CNS effects (somnolence or excitement) or tachycardia.

Reproductive/Nursing Safety

There is limited information available on the drug's use during pregnancy. While hyoscyamine crosses the placenta, reproductive studies in animals have not been performed. Two limited studies (322 & 281 pregnancies) in humans have been published evaluating hyoscyamine safety during pregnancy. One study showed no increase in congenital malformations, but the other showed a slight increase above normally expected malformations in infants. In humans, the FDA categorizes hyoscyamine as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Only traces of hyoscyamine are detected in milk. While no problems have been reported and risk to offspring cannot be ruled out, it is probably safe to use in nursing patients.

Overdosage/Acute Toxicity

The LD50 for hyoscyamine in rats is 375 mg/kg. Significant overdosage in animals may be serious and contacting an animal poison control center is advised. Toxicity is exhibited by intensified and prolonged anticholinergic effects; signs include: increased heart rate, CNS effects (behavior changes, depression, seizures), urinary retention, decreased gut sounds/motility, and mydriasis. Protocols to decrease oral absorption should be considered if overdose was recent. Severe anticholinergic effects can be treated with physostigmine or neostigmine, but it is suggested to do so only under the guidance of an animal poison control center. In humans, delirium or excitement has been treated with small doses of short-acting barbiturates or benzodiazepines. Hyoscyamine can be removed by hemodialysis.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving hyoscyamine and may be of significance in veterinary patients:

- **ANTACIDS containing magnesium, aluminum or calcium salts:** May interfere with hyoscyamine absorption

- **ANTICHOLINERGICS, OTHER** (atropine, glycopyrrolate, etc.): Additive actions and adverse effects can occur
- **ANTIHISTAMINES, FIRST GENERATION** (e.g., diphenhydramine): Additive actions and adverse effects can occur
- **PROKINETIC AGENTS** (e.g., cisapride, metoclopramide): Hyoscyamine may counteract their effects

Laboratory Considerations

No specific concerns noted with hyoscyamine

Doses

■ DOGS:

Note: The following dosages are assumed to be for the immediate release oral dosage forms. Potentially, the extended release tablets or capsules could be effective and reduce dosing frequency, particularly in larger dogs, but no data is available for using them.

- For irritable bowel syndrome: 0.003–0.006 mg/kg PO two to three times a day (Leib 2005)
- For long-term management of symptomatic patients with sinus node disease: 0.003–0.006 mg/kg PO q8h (Smith 2005)

Monitoring

- Clinical efficacy
- Adverse effects (e.g., heart rate, bowel or urinary elimination difficulties)

Client Information

- Contact the veterinarian if patient has difficulty urinating or defecating, dry eyes, difficulty swallowing, or demonstrates changes in behavior or activity

Chemistry/Synonyms

Hyoscyamine sulfate is a tertiary amine that occurs as white, odorless, crystals or crystalline powder. One gram is soluble in 0.5 mL of water or in 1 mL of alcohol. It is practically insoluble in ether.

Hyoscyamine may also be known as: daturin, duboisine, tropine-L-tropate. International trade names include: *Egazil Duretter*® and *Neo-Allospasmin*®.

Storage/Stability/Compatibility

Unless otherwise advised by the manufacturer, hyoscyamine sulfate oral products should be stored at room temperature, in tight containers, and protected from light. The injectable product should be stored at room temperature and protected from freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None as single ingredient products.

HUMAN-LABELED PRODUCTS:

Hyoscyamine Tablets: 0.125 mg, & 0.15 mg; *Anaspaz*® (Ascher), *ED-SPAZ*® (Edwards), *Levsin*® (Schwarz), *Cystospaz*® (PolyMedica), generic; (Rx)

Hyoscyamine Orally Disintegrating Tablets: 0.125 mg, & 0.25 mg; *Neosol*® (Breckenridge), *NuLev*® (Schwarz), *Symax FasTab*® (Capellon), *Mar-Spas*® (Marnel); (Rx)

Hyoscyamine Sublingual Tablets: 0.125 mg; *Levsin-SL*® (Schwarz), *Symax-SL*® (Capellon); (Rx)

Hyoscyamine Extended/Sustained-Release Tablets: 0.375 mg; *Levbid*® (Schwarz), *Symax-SR*®, generic; (Rx)

Hyoscyamine Extended/Timed-Release Capsules: 0.375 mg; *Levsinex*® (Schwarz), generic; (Rx)

Hyoscyamine Oral Solution: 0.125 mg/mL in 15 mL btl; *Levsin Drops*® (Schwarz), generic; (Rx)

Hyoscyamine Oral Elixir: 0.025 mg/mL (0.125mg/5mL) in pint bottles; *Levsin*® (Schwarz), generic; (Rx)

Hyoscyamine Oral Spray: 0.125 mg/spray in 30 mL btl; *IB-Stat*® (InKline); (Rx)

Hyoscyamine Injection: 0.05 mg/mL in 1 mL ampules and 10 mL multi-dose vials; *Levsin*® (Schwarz); (Rx)

IBAFLOXACIN

(ih-bah-floks-ah-sin) Ibaflin®

ORAL FLUOROQUINOLONE ANTIBIOTIC

Prescriber Highlights

- Oral fluoroquinolone used in dogs & cats primarily in Europe (not available in USA); oral dosage form is a gel in a “dial” syringe
- Similar to other veterinary fluoroquinolones, but may not be as effective against *Pseudomonas*
- Adverse effects can include diarrhea/soft feces, vomiting, dullness, anorexia & salivation
- No indication of causing ocular toxicity in cats

Uses/Indications

Ibafloxacin is used in dogs and cats to treat infections susceptible to it. It is labeled (in the UK) for treating dogs with dermal infections (superficial and deep pyoderma, wounds, abscesses) and in cats for treating dermal infections (soft tissue infections—wounds, abscesses) and upper respiratory tract infections caused by susceptible bacteria. Ibafloxacin may also be useful in treating urinary tract infections in dogs.

Pharmacology/Actions

Ibafloxacin is a bactericidal fluoroquinolone antibiotic and acts by inhibiting bacterial DNA-gyrase (a type-II topoisomerase), preventing DNA supercoiling and synthesis. It has a similar spectrum of activity as other veterinary commercially available agents (*Enterobacteriaceae*, *Staphylococcus* spp), but is not very effective against *Pseudomonas* spp, *Streptococcus* spp. or *Proteus mirabilis*.

Ibafloxacin's primary metabolites, 8-hydroxy-ibafloxacin and 7-hydroxy-ibafloxacin, are also active (but less so than ibafloxacin) and contribute to the drug's overall efficacy.

Pharmacokinetics

In dogs, oral bioavailability is about 70–80% with peak levels occurring around 1.5 hours after dosing. At 15 mg/kg, C_{max} was 6 mcg/mL; volume of distribution at steady state was 1.1 L/kg. Ibafloxacin is presumably metabolized in the liver to at least two metabolites, 8-hydroxy-ibafloxacin and 7-hydroxy-ibafloxacin. Both metabolites have been shown to be active, but less so than the parent compound. Elimination occurs in both the urine and feces as unchanged drug and glucuronidated metabolites. Total clearance is 8.7 mL/min/kg and elimination half-life, 5.2 hours.

In cats, ibafloxacin is rapidly absorbed after oral dosing. After dosing with food, peak levels occur in about 2–3 hours. Food slightly delays absorption, but peak levels are doubled and AUC increased when compared to fasted administration. Cats appear to metabolize and eliminate ibafloxacin in a similar manner as dogs; with repeated dosing, cats, unlike dogs, apparently show significant

increases over time in both AUC and Cmax of the parent drug and active metabolites.

Contraindications/Precautions/Warnings

The label (UK) states that for the majority of breeds, use is contraindicated in dogs less than 8 months of age and in giant breeds less than 18 months old. It is contraindicated in cats less than 8 months old. It is also contraindicated in dogs or cats with known quinolone hypersensitivity. It is stated that the product should only be used based upon susceptibility testing.

Adverse Effects

Adverse effects reported in dogs and cats include diarrhea, soft feces, vomiting, dullness, anorexia and salivation. These reportedly are mild and transient and occur with low frequency. No reports of ibafloxacin-associated ocular toxicity in cats were found.

In dogs, other fluoroquinolones have, in rare incidences, caused elevated hepatic enzymes, ataxia, seizures, depression, lethargy, or nervousness; these could potentially also occur with ibafloxacin.

Reproductive/Nursing Safety

The label (UK) states that ibafloxacin can be used during pregnancy in dogs, but that safety has not been established in pregnant cats or in lactating dogs and cats.

After dosing to goats, ibafloxacin was detected in milk only in scant quantities.

Overdosage/Acute Toxicity

Specific information not located for ibafloxacin. It is unlikely an acute overdose of ibafloxacin would result in signs more serious than anorexia or vomiting, but the adverse effects noted above could occur. If the overdose occurs in cats, ophthalmic monitoring is recommended. In dogs doses of 75 mg/kg/day (5X) were apparently well tolerated; cats receiving up to 75 mg/kg/day demonstrated salivation and vomiting.

Drug Interactions

Drug interactions associated with other fluoroquinolones would also be expected with ibafloxacin. The label states that ibafloxacin should not be used with **NSAIDs** in dogs with a history of seizures.

Other drug interactions with oral fluoroquinolones include:

- **ANTACIDS or SUPPLEMENTS CONTAINING CATIONS (iron, zinc, magnesium, aluminum, calcium):** May bind to ibafloxacin and prevent its absorption
- **CYCLOSPORINE:** Fluoroquinolones may exacerbate the nephrotoxicity of cyclosporine (used systemically)
- **NITROFURANTOIN:** May antagonize the antimicrobial activity of the fluoroquinolones; concomitant use is not recommended
- **SUCRALFATE:** May inhibit absorption of ibafloxacin, separate doses of these drugs by at least 2 hours
- **THEOPHYLLINE:** Ibafoxacin may increase theophylline blood levels

Laboratory Considerations

No specific laboratory concerns noted

Doses

■ DOGS/CATS:

For susceptible infections:

- a) Using the 3% oral gel for labeled indications (dogs: dermal infections; cats: dermal or respiratory tract infections): 15 mg/kg PO once daily. The syringe should be adjusted to the calculated dosage by setting the syringe ring (steps of 0.5 mL for the 15 mL syringe). Give at time of feeding. Duration treatment depends upon infection nature and severity; usu-

ally a 10-day course is sufficient, but can be extended until response is considered adequate. Reconsider treatment if no improvement in clinical response is seen after 5 days of therapy. In cases of deep pyoderma, reconsider treatment if sufficient improvement not seen in 21 days of treatment. (Label Information; *Ibaflin*®—Intervet UK)

Monitoring

- Clinical efficacy
- Adverse effects—GI (vomiting, hypersalivation, diarrhea, anorexia)

Client Information

- Give at the time of feeding
- Contact veterinarian if vomiting, diarrhea or lack of appetite persist or are severe
- Give as directed for the period the veterinarian specifies, even if the patient seems well

Chemistry/Synonyms

Ibafoxacin is a fluoroquinolone with a molecular weight of 275.28 and is available commercially as the racemate.

Ibafoxacin may also be known as S-25030 or *Ibaflin*®.

Storage/Stability

The oral gel should not be stored at temperatures more than 25°C. Once opened, it is recommended that the syringe be used within 8 weeks. Once a course of treatment is completed, dispose of unused product.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None in the USA

A 3% Oral Gel (30 mg ibafloxacin per gram of gel; 30.9 mg per mL of gel) in 15 mL syringes with 0.5 mL steps is available and labeled for use in dogs and cats in the UK, and in several other EU countries; *Ibaflin*® (Intervet); (Rx).

Depending on the market, 7.5% oral gel, 30 mg, 150 mg, 300 mg, and 900 mg tablets may be available for use in dogs.

HUMAN-LABELED PRODUCTS: None

IFOSFAMIDE

(eye-foss-fa-mide) Ifex®

ANTINEOPLASTIC

Prescriber Highlights

- Alkylating agent that may be useful in treating lymphomas & sarcomas in dogs & cats
- Very limited veterinary clinical experience to date
- May be very toxic (myelosuppression, nephrotoxic, bladder toxicity, neurotoxicity, GI, etc.)
- Must be given with saline diuresis & bladder-protective agent (mesna)

Uses/Indications

In small animals, ifosfamide may be of benefit as part of treatment protocols for a variety of neoplasms. Treatment of lymphomas and soft tissue sarcomas with ifosfamide in dogs and cats has been investigated to some extent; some efficacy has been demonstrated.

In humans, ifosfamide is used in various treatment protocols for testicular neoplasms, bone and soft tissue sarcomas, bladder cancer, lung cancer, cervical cancer, ovarian cancer, and some types of lymphomas.

Pharmacology/Actions

Ifosfamide appears to act similarly to other alkylating agents. Its active metabolites interfere with DNA replication and transcription of RNA, thereby disrupting nucleic acid function. It is cycle-phase nonspecific.

Pharmacokinetics

As ifosfamide is a prodrug and does not have pharmacologic activity, it must be biotransformed into active metabolites. Ifosfamide's pharmacokinetics are very complex and are not well understood. While normally given IV, it is well absorbed after SC injection or oral administration; bioavailabilities via these routes are 90% or greater. Ifosfamide and its metabolites are widely distributed and enter into both bone and CNS. Ifosfamide is converted into its metabolites primarily via oxidative pathways found in the liver and, to a smaller extent, in the lungs. It then is catalyzed (primarily in cells) into the primary active alkylating agent, ifosfamide mustard. Ifosfamide and its metabolites are primarily excreted via the kidney into urine.

Contraindications/Precautions/Warnings

Because of its toxicity, ifosfamide should only be used by clinicians experienced with the use of cytotoxic agents and able to adequately monitor the effects of therapy. Ifosfamide is contraindicated in patients hypersensitive to it or with severely depressed bone marrow function or active hemorrhagic cystitis. Ifosfamide should be used with extreme caution in patients with impaired renal function.

Ifosfamide must be used in conjunction with mesna to reduce the risk for hemorrhagic cystitis.

Adverse Effects

Dose related myelosuppression occurs with ifosfamide use; neutropenia generally occurs at 5–7 days post treatment, but may be delayed (14–21 days) with repeated dosing. Nadirs in cats are seen typically at day 7 or 8. Platelets can also be significantly impacted. Ifosfamide can damage bladder epithelium, and cause nephrotoxicity with resultant electrolyte abnormalities. Renal toxicity is primarily focused on proximal and distal tubular damage, but glomerular effects may occur. To reduce the incidence of nephrotoxicity and bladder toxicity, saline diuresis is performed (see dosages) and mesna given concomitantly to reduce bladder epithelial toxicity (see below). Volume overload with pulmonary edema may result however, particularly in patients with preexisting cardiac disease. Other adverse effects that may occur include: hypersensitivity reactions, nausea, particularly during infusion, vomiting, neurotoxicity (somnolence to confusion, coma, encephalopathy), alopecia, and abnormal liver function tests.

Administering mesna with ifosfamide significantly reduces the incidence and severity of ifosfamide-induced hemorrhagic cystitis and hematuria. Mesna interacts with metabolites of ifosfamide that cause the toxicity. Because mesna is hydrophilic, it does not enter most cells and, therefore, does not appear to significantly reduce the anti-tumor efficacy of ifosfamide. Mesna does not prevent or reduce the incidence of other adverse effects associated with ifosfamide (e.g., myelosuppression, GI effects, neurotoxicity, renal toxicity).

Like other cytotoxic drugs, ifosfamide should be handled and disposed of appropriately.

Reproductive/Nursing Safety

In pregnant humans, ifosfamide is designated by the FDA as a category **D** drug (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) Teratogenic and fetotoxic effects have been demonstrated at usual doses in humans and laboratory animals.

Ifosfamide is excreted in maternal milk. If this drug is being used in lactating mothers, consider using milk replacer.

Overdosage/Acute Toxicity

There is limited information available on acute overdoses. It would be expected that toxicity would be exacerbations of the adverse effects seen at usual doses. No specific antidote (including mesna) is known; treatment is supportive. Methylene blue (50 mg in a 1–2% aqueous solution IV over 5 minutes) has been suggested to treat ifosfamide-induced encephalopathy in humans.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ifosfamide and may be of significance in veterinary patients:

- **BENZODIAZEPINES:** A study where mice received benzodiazepines (**diazepam**, **chlordiazepoxide**, **oxazepam**) prior to receiving ifosfamide had increased concentrations of active ifosfamide and showed increased toxicity to the drug; clinical significance has not been determined for human (or dog or cat) patients
- **CISPLATIN:** Ifosfamide may enhance cisplatin-induced ototoxicity and nephrotoxicity
- **MYELOSUPPRESSIVE DRUGS, OTHER** (e.g., other **antineoplastics**, **chloramphenicol**, **flucytosine**, **amphotericin B**, or **colchicine**): Other bone marrow depressant drugs may cause additive myelosuppression when used with ifosfamide

Laboratory Considerations

No specific laboratory interactions or considerations were noted.

Doses

■ DOGS:

- a) For treating lymphomas and soft tissue sarcomas: Give IV saline at 18.3 mL/kg/hr for 6 hours. Give ifosfamide at 350 mg/m² (if patient weighs less than 10 kg), 375 mg/m² (if greater than 10 kg) IV during the second 30 minutes of the 6-hour infusion. Mesna at a dose of 20% of the ifosfamide dose is given as an IV bolus at the start of the IV infusion and again 2 and 5 hours after the ifosfamide infusion. Repeat every 3 weeks. (Brewer 2003)

■ CATS:

- a) For treating lymphomas and soft tissue sarcomas: Give IV saline at 18.3 mL/kg/hr for 6 hours. Give ifosfamide at 350–500 mg/m² IV during the second 30 minutes of the 6-hour infusion. Mesna at a dose of 20% of the ifosfamide dose is given as an IV bolus at the start of the IV infusion and again 2 and 5 hours after the ifosfamide infusion. Repeat every 3 weeks. (Brewer 2003)
- b) For sarcomas: 900 mg/m² (with mesna and saline diuresis) IV q3 weeks. (Smith 2003a)

Monitoring

- CBC with platelets (baseline and before re-dosing)
- Renal function with electrolytes (baseline and before re-dosing)
- Urinalysis baseline and periodic)
- Liver function (baseline and periodic)
- Other adverse effects (volume overload/pulmonary edema, neurotoxicity, GI toxicity)
- Efficacy

Client Information

- Clients should understand the relative investigational nature of using ifosfamide in dogs or cats and accept the possibility of severe adverse effects due to its use.
- Owners should be instructed to avoid contact with animal's saliva or urine for at least 24 hours after dosing.

Chemistry/Synonyms

An alkylating agent structurally related to cyclophosphamide, ifosfamide occurs as a white, crystalline powder with a melting point of 40°C. It is freely soluble in water and very soluble in alcohol. A 10% solution in water has a pH between 4 and 7.

Ifosfamide may also be known as: MJF-9325, NSC-109724, Z-4942, *Ifex*®, *Asoifos*®, *Cuantil*®, *Duvaxan*®, *Fentul*®, *Holoxan*®, *Holaxane*®, *Ifex*®, *IFO-cell*®, *IFX*®, *Ifocris*®, *Ifolem*®, *Ifomida*®, *Ifos*®, *Ifosmixan*®, *Ifoxan*®, *Mitoxana*®, *Seromida*®, or *Troxanol*®.

Storage/Stability/Compatibility

Ifosfamide powder for injection should be stored at 20–25°C (68–77°F). It should be protected from temperatures greater than 30°C (86°F) as the drug may liquefy at temperatures greater than 35°C (95°F). Once reconstituted with sterile water for injection or bacteriostatic water for injection the solution is stable for 24 hours when refrigerated. (**Note:** one reference states that bacteriostatic water for injection containing benzyl alcohol caused the solution to become turbid at concentrations of ifosfamide greater than 60 mg/mL. No such incompatibility occurred when using bacteriostatic water for injection containing parabens.) The reconstituted drug is **compatible** with D₅W, normal saline, or lactated Ringer's and is stable for up to 24 hours when refrigerated. Ifosfamide is compatible and stable when mixed with mesna in D₅W or lactated Ringer's.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ifosfamide Powder: for IV infusion 1 g with 200 mg amps of Mesnex (mesna) in single dose vials; 3 g with 400 mg amps of Mesnex (mesna) in single dose vials; *Ifex*® (Mead Johnson Oncology); Ifosfamide (American Pharmaceutical Partners); (Rx)

Imidacloprid — See the listing in the **Topical Dermatologic** section in the appendix

IMIDOCARB DIPROPINATE

(i-*mid*-oh-karb) Imizol®

ANTIPROTOZOAL

Prescriber Highlights

- Antiprotozoal useful against *Babesia* & related parasites
- Contraindications: Patients exposed to cholinesterase-inhibiting drugs (e.g., pyridostigmine), pesticides, or chemicals
- Caution: Impaired lung, hepatic or renal function; safety in puppies, pregnant, lactating, or breeding animals has not been established
- Adverse Effects: Most common are pain during injection & mild cholinergic signs (salivation, nasal drip, & brief episodes of vomiting); less common: panting, diarrhea, injection site inflammation (rarely ulceration), & restlessness
- Not for intravenous administration

Uses/Indications

Imidocarb is approved for use to treat *Babesia canis* infections (babesiosis) in dogs, but the drug may also be efficacious against *Ehrlichia canis* in this species. Imidocarb may be of benefit in treating *Babesia* and related parasitic diseases in a variety of domestic and exotic animals.

Imidocarb appears to be more effective against *B. canis* than *B. gibsoni*.

Pharmacology/Actions

Imidocarb is thought to act by combining with nucleic acids of DNA in susceptible organisms, causing the DNA to unwind and denature. This damage to DNA is believed to inhibit cellular repair and replication.

Pharmacokinetics

No specific information was located for this drug.

Contraindications/Precautions/Warnings

Do not use imidocarb in patients exposed to cholinesterase-inhibiting drugs, pesticides, or chemicals. The manufacturer states to consider risks versus benefits before treating dogs with impaired lung, hepatic, or renal function. Donkeys appear to be sensitive to the toxic effects of the drug.

Adverse Effects

Most commonly reported adverse effects in dogs include pain during injection and mild cholinergic signs (salivation, nasal drip and brief episodes of vomiting). Less commonly reported effects include panting, diarrhea, injection site inflammation (rarely ulceration), and restlessness. Rarely, severe renal tubular or hepatic necrosis have occurred. Imidocarb has reportedly caused an increase incidence of tumor formation in rats.

Horses given high therapeutic dosages (4 mg/kg) develop lacrimation, sweating, and serous nasal discharge for 30 minutes after treatment.

Do not administer intravenously.

Reproductive/Nursing Safety

Safety in puppies, pregnant, lactating, or breeding animals has not been established.

Overdosage/Acute Toxicity

Dogs receiving a dosage of 9.9 mg/kg (1.5X labeled dose) showed signs of liver injury (slightly increased liver enzymes), pain and swelling at the injection site, and vomiting. Overdoses or chronic toxicity may present with cholinergic signs (vomiting, weakness, lethargy, salivation) or adverse changes in liver, kidney, lung, or intestinal function. Treatment with atropine may be useful to treat cholinergic signs associated with imidocarb.

The LD-50 in horses is reportedly 16 mg/kg.

Drug Interactions

The manufacturer warns not use imidocarb in patients exposed to **cholinesterase-inhibiting drugs, pesticides, or chemicals.**

Laboratory Considerations

- Imidocarb IM injections may cause significant increases in **creatinine kinase (CK)**.

Doses**■ DOGS:**

For treatment of babesiosis:

- 6.6 mg/kg IM or SC; repeat dose in 2 weeks (Package Insert; *Imizol*®—Schering)
- 5–6.6 mg/kg IM or SC; repeat in 14 days or 7.5 mg/kg IM or SC once. A single dose of 6 mg/kg the day following a dose of diminazene at 3.5 mg/kg has also been shown to clear the infection. (Taboada and Lobetti 2006)

For treatment of Ehrlichiosis:

Note: A study (Eddlestone, Neer et al. 2005) demonstrated that imidocarb was not effective (alone) in clearing *Ehrlichia canis* from the blood of experimentally infected dogs.

- 5 mg/kg IM or SC; repeat in 14–21 days or 5 mg/kg IM repeat in 84 days (Greene and Watson 1998)
- In particularly severe cases, imidocarb at 5 mg/kg SC (in a single injection or two injections 15 days apart) with doxycycline at 10 mg/kg/day for 28 days (Sainz 2002)

For treatment of hepatozoonosis (*H. canis*):

- 5 mg/kg IM or SC; every 14 days until parasitemia clears. Usually 1–2 injections are sufficient. (Macintire 1999)

■ CATS:

For treatment of *Cytauxzoon felis*:

- 5 mg/kg IM every 2 weeks (Lappin 2000)
- 2–5 mg/kg IM; generally repeated 7 days after initial dose. Efficacy not proven. Cholinergic effects can be mitigated by pre-treating with atropine. Must also give supportive therapy (IV fluids, prophylactic heparin, nutritional/nursing care, analgesia, and potentially transfusion) (Cohn 2006)
- 5 mg/kg IM once and then 14 days later. (Greene, Meinkoth et al. 2006)

For treatment of recurrent Haemobartonellosis (*Mycoplasma haemofelis*, *Mycoplasma Haemominutum*):

- Doxycycline is preferred, but in cats intolerant of doxycycline the following alternatives may be effective: imidocarb can be used at 5 mg/kg IM, SC every 14 days until able to maintain a normal PCV. Other optional treatment includes enrofloxacin at 5 mg/kg PO daily or marbofloxacin at 2.75 mg/kg PO daily. (Lappin 2002b), (Lappin 2006c)

■ HORSES:

For treatment of equine piroplasmiasis (*Babesia caballi*; *Babesia equi*):

- 2.2 mg/kg IM will generally allow clinical signs to subside. To eliminate *B. caballi* inject 2 mg/kg IM once a day for 2 days. *B. equi* more difficult to eliminate; there has been some suc-

cess reported when imidocarb is given at 4 mg/kg IM at 72 hour intervals for 4 doses. (Sellon 2004)

■ SHEEP:

For treatment of babesiosis:

- 1.2 mg/kg IM; repeat in 10–14 days (McHardy, Woolon et al. 1986)

Monitoring

- Efficacy
- Adverse effect profile

Chemistry/Synonyms

Imidocarb dipropionate is a diamidine of the carbanalide series of antiprotozoal compounds.

Imidocarb may also be known as 4A65 (imidocarb hydrochloride) and *Imizol*®.

Storage/Stability

The injection should be stored between 2°–25°C (36°–77°F) and protected from light.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Imidocarb Dipropionate for IM or SC Injection: 120 mg/mL in 10 mL multi-dose vials; *Imizol*® (Schering-Plough); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS: None

IMIPENEM-CILASTATIN SODIUM

(ih-me-peh-nem sye-la-sta-tin) Primaxin®

CARBAPENEM ANTIBIOTIC**Prescriber Highlights**

- Broad spectrum antibiotic/deactivating enzyme inhibitor combination used for serious infections where a single agent is desired
- Contraindications/Cautions: Patients hypersensitive to it or other beta-lactams, patients with renal impairment (dosages adjustment may be required), CNS disorders (e.g., seizures, head trauma)
- Adverse Effects: GI effects, CNS toxicity (seizures, tremors), hypersensitivity, & infusion reactions (thrombophlebitis)
- Too rapid IV infusions may cause GI toxicity or other untoward effects; Rarely: increases in renal or hepatic function tests; hypotension or tachycardia
- Separate dosage forms for IM or IV use
- Can be expensive

Uses/Indications

Imipenem may be useful in equine or small animal medicine to treat serious infections when other less expensive antibiotics are ineffective or have unacceptable adverse effect profiles.

Pharmacology/Actions

This fixed combination of a carbapenem antibiotic (imipenem) and an inhibitor (cilastatin) of dehydropeptidase I (DHP I) has a very broad spectrum of activity. Imipenem is generally considered to be a bactericidal agent, but may be static against some bacteria.

It has an affinity for and binds to most penicillin-binding protein sites, thereby inhibiting bacterial cell wall synthesis.

Imipenem has activity against a wide variety of bacteria, including gram-positive aerobic cocci (including some bacteriostatic activity against some enterococci), gram-positive aerobic bacilli (including static activity against *Listeria*), gram-negative aerobic bacteria (*Haemophilus*, Enterobacteriaceae, many strains of *Pseudomonas aeruginosa*), and anaerobes (including some strains of Bacteroides).

Imipenem is not efficacious for treating infections caused by methicillin-resistant staphylococci or resistant strains of *Enterococcus faecium*.

Cilastatin inhibits the metabolism of imipenem by DHP 1 on the brush borders of renal tubular cells. This serves two functions: it allows higher urine levels and may protect against proximal renal tubular necrosis that can occur when imipenem is used alone.

Pharmacokinetics

Neither drug is absorbed appreciably from the GI tract and, therefore, they are given parenterally. Bioavailability after IM injection is approximately 95% for imipenem and 75% for cilastatin. In dogs, bioavailability of imipenem after SC injection is complete. Imipenem is distributed widely throughout the body, with the exception of the CSF. Imipenem crosses the placenta and is distributed into milk. When given with cilastatin, imipenem is eliminated by both renal and non-renal mechanisms. Approximately 75% of a dose is excreted in the urine and about 25% is excreted by unknown non-renal mechanisms. Half-lives in patients with normal renal function range from 1–3 hours on average. In horses average elimination time is 70 minutes; 60 minutes in dogs.

Contraindications/Precautions/Warnings

The potential risks versus benefits should be carefully weighed before using imipenem/cilastatin in patients hypersensitive to it or other beta-lactam antibiotics (e.g., penicillins, cephalosporins as partial cross-reactivity may occur), with renal function impairment (dosages may need to be reduced or time between doses lengthened), or with CNS disorders (e.g., seizures, head trauma) as CNS adverse effects may be more likely to occur.

Adverse Effects

Potential adverse effects include: GI effects (vomiting, anorexia, diarrhea), CNS toxicity (seizures, tremors), hypersensitivity (pruritus, fever to anaphylaxis) and infusion reactions (thrombophlebitis; too rapid IV infusions may cause GI toxicity or other untoward effects).

Rarely, transient increases in renal (BUN or serum creatinine values) or hepatic (AST/ALT/Alk Phosphatase) function tests may be noted, as well as, hypotension or tachycardias.

Reproductive/Nursing Safety

While no teratogenic effects have been noted in animal studies, safe use during pregnancy has not been firmly established. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

While imipenem enters milk, no adverse effects attributable to it have been noted in nursing offspring.

Overdosage/Acute Toxicity

Little information is available. The LD₅₀ of imipenem:cilastatin in a 1:1 ratio in mice and rats is approximately 1 g/kg/day. Acute overdoses should be handled by halting therapy then treating supportively and symptomatically.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving imipenem-cilastatin and may be of significance in veterinary patients:

■ **AMINOGLYCOSIDES:** Additive effects or synergy may result when aminoglycosides are added to imipenem/cilastatin therapy, particularly against *Enterococcus*, *Staph. aureus*, and *Listeria monocytogenes*. There is apparently neither synergy nor antagonism when used in combination against Enterobacteriaceae, including *Pseudomonas aeruginosa*.

■ **BETA-LACTAM ANTIBIOTICS:** Antagonism may occur when used in combination with other beta lactam antibiotics against several Enterobacteriaceae (including many strains of *Pseudomonas aeruginosa* and some strains of *Klebsiella*, *Enterobacter*, *Serratia*, *Enterobacter*, *Citrobacter*, and *Morganella*); clinical importance of this interaction is unclear, but at present it is not recommended to use imipenem in conjunction with other beta-lactam antibiotics.

■ **CHLORAMPHENICOL:** May antagonize the antibacterial effects of imipenem (*in vitro* evidence)

■ **PROBENECID:** May increase concentrations and elimination half-life of cilastatin, but not imipenem; concurrent use not recommended

■ **TRIMETHOPRIM/SULFA:** Synergy may occur against *Nocardia asteroides* when imipenem is used in combination with trimethoprim/sulfa

Laboratory Considerations

■ Imipenem may cause a false-positive urine glucose determination when using the cupric sulfate solution test (e.g., *Clinitest*®), Benedict's solution or Fehling's solution. Enzymatic glucose oxidase based tests are not affected (e.g., *Tes-Tape*®, *Clinistix*®).

Doses

Note: When giving IM, the manufacturer recommends a 21g needle (deep IM) with aspiration, to avoid IV administration.

■ DOGS & CATS:

For susceptible infections:

- 5–10 mg/kg IV, SC or IM (IM form is different) q8h (Aucoin 2002b)
- 2–5 mg/kg every 8 hours (Lappin 1997)
- 5–10 mg/kg IV (given over 30 minutes) q6h or IM q6h (mixed with 1% lidocaine to reduce pain). **Note:** Cannot interchange IV and IM dosage forms. (Trepanier 1999)
- For tissue infections: 3–7.5 mg/kg IV, SC or IM q4–6h for 3–5 days; for sepsis, more resistant organisms give 5 mg/kg IV q4h (multi-drug resistant bacteria may require q2h dosing) for 3–5 days (Greene, Hartmann et al. 2006)
- For treatment of Nocardiosis: 2–5 mg/kg IV q8h (Lemarie 2003a)

■ HORSES:

For susceptible infections:

- Adult horses: 10–20 mg/kg via slow IV (over a 10 minute period) q6h; alternatively a CRI of 16 mcg/kg/minute should maintain synovial concentrations greater than 1 mcg/mL. (Orsini, Moate et al. 2005)
- Foals: 20 mg/kg IV q6–8h (Brumbaugh 1999)
- Foals: 10–20 mg/kg IV q6h; seizures have been reported (Wilkins 2004b)
- Foals: 5–10 mg/kg IM q12h. (McKenzie 2005)

Monitoring

- Efficacy
- Adverse effects (including renal and hepatic function tests if treatment is prolonged or patient's renal or hepatic functions are in question)

Client Information

- Imipenem/cilastatin should be administered in an inpatient setting.
- Clients should be informed of the cost of using this medication.

Chemistry/Synonyms

Imipenem monohydrate is a carbapenem antibiotic that occurs as white or off-white, non-hygroscopic, crystalline compound. At room temperature, 11 mg are soluble in 1 mL of water. Cilastatin sodium, an inhibitor of dehydropeptidase I (DHP I), occurs as an off-white to yellowish, hygroscopic, amorphous compound. More than 2 grams are soluble in 1 mL of water.

The commercially available injections are available in a 1:1 fixed dose ratio. The solutions are clear to yellowish in color. pH after reconstitution ranges from 6.5 to 7.5. These products have sodium bicarbonate added as a buffer. The suspensions for IM use are white to light tan in color.

Imipenem may also be known as: N-formimidoyl thienamycin, imipemide, MK-787, and MK-0787; multi-ingredient preparations: *Imipem*®, *Klonam*®, *Primaxin*®, *Tenacid*®, *Tienam*®, *Tracix*®, and *Zienam*®.

Storage/Stability/Compatibility

Commercially available sterile powders for injection should be stored at room temperature (<25°C). After reconstitution, the solution is stable for 4 hours at room temperature; 10 hours when refrigerated. If other diluents are used, stability times may be reduced (see package insert). Do not freeze solutions. The manufacturer does not recommend admixing with other drugs.

After reconstitution the sterile powder for suspension with 1% lidocaine HCl injection, the suspension should be used within one hour.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Imipenem Cilastatin Powder for Injection: 250 mg and 250 mg cilastatin (0.8 mEq sodium); 500 mg and 500 mg cilastatin (1.6 mEq sodium) in vials, infusion bottles and *ADD-Vantage* vials; *Primaxin*® I.V. (Merck); (Rx)

Imipenem Cilastatin Powder for Injection: 500 mg and 500 mg cilastatin (1.4 mEq sodium); 750 mg and 750 mg cilastatin (2.1 mEq sodium) in vials; *Primaxin*® I.M. (Merck); (Rx)

IMIPRAMINE HCL

IMIPRAMINE PAMOATE

(im-ip-ra-meen) Tofranil®

TRICYCLIC ANTIDEPRESSANT**Prescriber Highlights**

- Tricyclic "antidepressant" used primarily for cataplexy & urinary incontinence (dogs/cats) narcolepsy & ejaculatory dysfunction (horses)
- May reduce seizure thresholds in epileptic animals
- Very toxic in overdoses to both animals & humans
- May be teratogenic
- Adverse Effects: Sedation & anticholinergic effects (tachycardia, hyperexcitability, tremors) most likely

Uses/Indications

In dogs and cats, imipramine has been used to treat cataplexy and urinary incontinence. In horses, imipramine has been used to treat narcolepsy and ejaculatory dysfunction (no parenteral dosage forms available).

Pharmacology/Actions

Imipramine and its active metabolite, desipramine, have a complicated pharmacologic profile. From a slightly oversimplified viewpoint, they have 3 main characteristics: blockage of the amine pump, thereby increasing neurotransmitter levels (principally serotonin, but also norepinephrine), sedation, and central and peripheral anticholinergic activity. While not completely understood, the antienuretic activity of imipramine is thought to be related to its anticholinergic effects. In animals, tricyclic antidepressants are similar to the actions of phenothiazines in altering avoidance behaviors.

Pharmacokinetics

Imipramine is rapidly absorbed from both the GI tract and from parenteral injection sites. Peak levels occur within 1–2 hours after oral dosing. Imipramine and desipramine enter the CNS and maternal milk in levels equal to that found in maternal serum. The drug is metabolized in the liver to several metabolites, including desipramine, which is active. In humans the terminal half-life is approximately 8–16 hours.

Contraindications/Precautions/Warnings

These agents are contraindicated if prior sensitivity has been noted with any other tricyclic. Concomitant use with monoamine oxidase inhibitors is generally contraindicated.

Adverse Effects

While there is little experience with this drug in domestic animals, the most predominant adverse effects seen with the tricyclics are related to their sedating and anticholinergic (dry mouth, constipation, tachycardia, hyperexcitability, tremors) properties. They can cause CNS stimulation (seizures) however, and adverse effects can run the entire gamut of systems including hematologic (bone marrow suppression), GI (diarrhea, vomiting), endocrine, etc.

Reproductive/Nursing Safety

Isolated reports of limb reduction abnormalities have been noted; restrict use to pregnant animals when the benefits clearly outweigh

the risks. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Imipramine is excreted into milk in low concentrations (approximate milk:plasma ratio of 0.4 to 1.5).

Overdosage/Acute Toxicity

Overdosage with tricyclics can be life-threatening (arrhythmias, cardiorespiratory collapse). Because the toxicities and therapies for treatment are complicated and controversial, it is recommended to contact a poison control center for further information in any potential overdose situation.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving imipramine and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS:** Because of additive effects, use with imipramine cautiously
- **CIMETIDINE:** May inhibit tricyclic antidepressant metabolism and increase the risk of toxicity
- **CISAPRIDE:** Increased risk for prolonged QT interval
- **CLONIDINE:** Tricyclics may increase blood pressure
- **CNS DEPRESSANTS:** Because of additive effects, use with imipramine cautiously
- **LEVODOPA:** Imipramine may decrease levodopa oral absorption
- **PHENOBARBITAL:** May decrease tricyclic levels
- **QUINIDINE:** Increased risk for imipramine toxicity
- **RIFAMPIN:** May decrease tricyclic blood levels
- **SSRIs** (e.g., **fluoxetine**, **paroxetine**, **sertraline**, etc.): Increased risk for serotonin syndrome
- **SYMPATHOMIMETIC AGENTS:** Use in combination with sympathomimetic agents may increase the risk of cardiac effects (arrhythmias, hypertension, hyperpyrexia)
- **MONOAMINE OXIDASE INHIBITORS** (including **amitraz**, and possibly **selegiline**): Concomitant use (within 14 days) with monoamine oxidase inhibitors is generally contraindicated (serotonin syndrome)
- **THYROID AGENTS:** May increase risk for cardiac arrhythmias

Laboratory Considerations

- **ECG:** Tricyclics can widen QRS complexes, prolong PR intervals and invert or flatten T-waves on ECG
- **GLUCOSE, BLOOD:** Tricyclics may alter (increase or decrease) blood glucose levels

Doses

■ DOGS:

For urethral incompetence:

- a) 5–15 mg (total dose) PO q12h (Labato 1994), (Bartges 2006a)
- b) For urinary incontinence when other agents fail: 5–20 mg (total dose) PO q12h (Lane 2000)

For cataplexy:

- a) 0.5–1 mg/kg PO q8h; titrate dose based on clinical effect (Fenner 1994); (Coleman 1999)

For behavior-related conditions:

- a) For adjunctive treatment of separation anxiety or other tricyclic antidepressant-responsive behavior disorders: 2.2–4.4 mg/kg PO once to twice daily (Marder 1991)

For adjunctive treatment of pain:

- a) For adjunctive cancer pain treatment: 0.5–1 mg/kg PO q8h (Lester and Gaynor 2000)

■ CATS:

For urethral incompetence:

- a) 2.5–5 mg (total dose) PO q12h (Labato 1994); (Bartges 2006a)

For adjunctive cancer pain treatment:

- a) 2.5–5 mg (total dose) PO q12h (Lester and Gaynor 2000)

■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

Note: The injectable product is no longer marketed in the USA.

- a) For pharmacologic induced ejaculation: 2 mg/kg IV. If imipramine alone does not induce erection and ejaculation in 10–15 minutes, give xylazine 0.2–0.3 mg/kg IV. (Samper 2004)
- b) For narcolepsy/cataplexy: 0.55 mg/kg IV or 250–750 mg (total dose) orally. PO administration produces inconsistent results. (Andrews and Matthews 2004)

Monitoring

- Efficacy
- Adverse effects

Client Information

- All tricyclics should be dispensed in child-resistant packaging and kept well away from children or pets.
- Inform clients that several weeks may be required before efficacy is noted and to continue dosing as prescribed.

Chemistry/Synonyms

A tricyclic antidepressant agent, imipramine is available commercially in either the hydrochloride or pamoate salts. Imipramine HCl occurs as an odorless or practically odorless, white to off-white crystalline powder that is freely soluble in water or alcohol. Imipramine pamoate occurs as a fine yellow powder that is practically insoluble in water, but soluble in alcohol. The HCl injection has a pH of 4–5.

Imipramine HCl may also be known as: imipramini chloridum, imipramini hydrochloridum, imizine, *Antidep*®, *Celamine*®, *Depramina*®, *Depsonil*®, *Elepsin*®, *Ethipramine*®, *Imipra*®, *Imiprex*®, *Imiprin*®, *Imp-Tab*®, *Impril*®, *Janimine*®, *Melipramine*®, *Mipralin*®, *Novo-Pramine*®, *Praminan*®, *Primonil*®, *Pryleugan*®, *Sermonil*®, *Surplix*®, *Talpramin*®, and *Tofranil*®.

Storage/Stability

Imipramine HCl tablets and the pamoate capsules should be stored in tight, light resistant containers, preferably at room temperature. The HCl injection should be stored at temperatures less than 40°C and freezing should be avoided. Expiration dates for oral HCl products are from 3–5 years after manufacture; for the pamoate, 3 years.

Imipramine HCl will turn yellow to reddish on exposure. Slight discoloration will not affect potency, but marked changes in color are associated with a loss of potency.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Imipramine HCl Tablets: 10 mg, 25 mg & 50 mg; *Tofranil*® (Norvartis), generic; (Rx)

Imipramine Pamoate Capsules: 75 mg, 100 mg, 125 mg & 150 mg; *Tofranil®-PM* (Norvartis), generic; (Rx)

Imiquimod—see the Topical Dermatologic section in the appendix

INAMRINONE LACTATE

(in-*am*-ri-none) Amrinone, Inocor®

INOTROPIC AGENT

Prescriber Highlights

- ▶ **Second-line agent for short-term management of CHF**
- ▶ **Contraindicated with severe aortic or pulmonic valve disease; use extreme caution with hypertrophic cardiomyopathy**
- ▶ **Monitoring of cardiac effects & adverse effects mandatory**

Uses/Indications

Inamrinone is considered a second line agent for the short-term management of CHF. It was originally called amrinone, but was changed to inamrinone presumably to avoid confusion with amiodarone.

Pharmacology/Actions

The exact mechanisms of amrinone's cardiac effects are not well understood. It is thought the primary effects are due to its vasodilatory effects, thereby reducing both preload and afterload. Because it inhibits phosphodiesterase, it may directly stimulate cardiac contractility.

Pharmacokinetics

Although no oral commercial dosage forms are available, inamrinone is rapidly absorbed after oral administration. After initial intravenous injection, effects begin within 2–3 minutes and peak effects occur within 10 minutes. Cardiac effects generally correlate with the drug's serum level. Amrinone's distribution characteristics are not well described. In humans, it has an apparent volume of distribution of 1.2 L/kg. It exhibits low to moderate protein binding (10–49%). It is unknown if it crosses the placenta, blood-brain barrier, or enters into maternal milk. Inamrinone is eliminated primarily via the kidneys. About 63% of a dose is excreted (10–40% unchanged) into the urine. The duration of effect (in humans) is dose related with a single dose lasting from 30 minutes after a 0.75 mg/kg IV dose to 2 hours after a 3 mg/kg dose. Plasma half-lives may be prolonged in patients with CHF.

Contraindications/Precautions/Warnings

Inamrinone is considered contraindicated when severe aortic or pulmonic valve disease is present or in patients hypersensitive to it or bisulfites. The potential risks versus benefits of therapy with inamrinone should be carefully considered in patients with hypertrophic cardiomyopathy.

Adverse Effects

Use in domestic animals is very limited. Adverse effects that potentially could be seen include arrhythmias (drug is not inherently arrhythmogenic, but CHF patients are more susceptible to arrhythmias secondary to any drug), hypotension, GI effects (vomiting, diarrhea), thrombocytopenia (particularly with prolonged therapy), hepatotoxicity, and hypersensitivity reactions (variable symptoma-

tology: pericarditis to myositis, etc.). Inamrinone should only be used in settings where appropriate monitoring may be employed.

Reproductive/Nursing Safety

Reproductive safety data are conflicting; use only when benefits outweigh risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether inamrinone is secreted in milk; exercise caution.

Overdosage/Acute Toxicity

Only one case (human) of accidental massive overdose resulting in death has been reported (causal relationship not unequivocally established). Because hypotension is the primary problem that would generally be seen, circulatory support should be instituted.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving inamrinone lactate and may be of significance in veterinary patients:

- **DIGOXIN:** Digoxin and other inotropic cardiac glycosides have an additive effect with inamrinone; this is generally considered a positive drug interaction.
- **DISOPYRAMIDE:** May cause excessive hypotension when used with inamrinone

Doses

■ DOGS:

As a positive inotropic agent:

- a) 1–3 mg/kg IV as a slow IV bolus followed by a 10–100 mcg/kg/min IV CRI; ½ the initial bolus may be administered 20–30 minutes after the first bolus. (Kittleson 2006a)
- b) 1–3 mg/kg IV followed by a 30–100 mcg/kg/min IV CRI (Muir and Bonagura 1994)
- c) 2 mg/kg bolus IV, followed by 30–300 mcg/kg/min IV infusion (Fox 2003a)
- d) For patients coming off cardiopulmonary bypass with poor cardiac contractility: 0.25–0.6 mg/kg loading, then 5–45 mcg/kg/min CRI (Nelson 2003a)

■ CATS:

- a) 1–3 mg/kg IV followed by 30–100 mcg/kg/min IV infusion (Muir and Bonagura 1994)
- b) 1–3 mg/kg IV as a slow IV bolus followed by a 10–100 mcg/kg/min IV CRI; ½ the initial bolus may be administered 20–30 minutes after the first bolus. (Kittleson 2006a)

Monitoring

- Blood pressure
- Heart rate/rhythm; continuous ECG recommended
- Body weight
- Platelet counts

Client Information

- Clients should be made aware of the “investigational nature” of the use of this drug in dogs or cats

Chemistry/Synonyms

Formerly known as amrinone lactate, inamrinone is unrelated structurally to cardiac glycosides or catecholamines, and is a bipyridine cardiac inotropic agent. It occurs as a pale yellow, crystalline powder and is insoluble in water and slightly soluble in alcohol. The

commercially available injection has a pH adjusted to 3.2–4 and an osmolality of 101 mOsm/L.

Inamrinone may also be known as: amrinone, Win-40680, Amcoral®, Inocor®, Vesistol®, and Wincoram®.

Storage/Stability/Compatibility

The commercially available injection should be stored at room temperature and protected from light. It is stable for 2 years after manufacture.

Inamrinone lactate for injection is reportedly **compatible** with 0.45% or 0.9% sodium chloride injection, propranolol HCl, verapamil HCl. It is reportedly **incompatible** with solutions containing dextrose or sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Inamrinone Lactate for Injection: 5 mg/mL (as lactate) in 20 mL amps; generic (Abbott Hospital); (Rx)

INSULIN INJECTION, REGULAR (CRYSTALLINE ZINC) INSULIN, ISOPHANE SUSPENSION (NPH) INSULIN, PROTAMINE ZINC SUSPENSION (PZI) INSULIN, PORCINE ZINC SUSPENSION (LENTE) INSULIN, GLARGINE

(In-su-lin)

HORMONE

Note: Insulin preparations available to the practitioner are in a constant state of change. It is highly recommended to review current references or sources of information pertaining to insulin therapy for dogs and cats to maximize efficacy of therapy and reduce the chance for errors.

Prescriber Highlights

- ▶ Pancreatic hormone used to treat diabetic ketoacidosis, uncomplicated diabetes mellitus, & as adjunctive therapy in treating hyperkalemia
- ▶ Contraindications: No absolute contraindications
- ▶ Adverse Effects: Hypoglycemia, insulin-induced hyperglycemia ("Somogyi effect"), insulin antagonism/resistance, rapid insulin metabolism, & local reactions to the "foreign" proteins
- ▶ Do not confuse insulin types, strengths, syringes
- ▶ Drug Interactions

Monograph by Dinah Jordan, PharmD, DICVP

Uses/Indications

Insulin preparations have been used for the adjunctive treatment of diabetic ketoacidosis, uncomplicated diabetes mellitus, and as adjunctive therapy in treating hyperkalemia. Insulin treatment in veterinary species has been primarily in dogs and cats. Experience using insulin in other veterinary species is limited.

Regular insulin is commonly used for stabilization of the diabetic patient and is the only formulation appropriate for intravenous administration (IV); it is also administered by intramuscular (IM) and subcutaneous (SC) injection. Only regular insulin should be used in patients with diabetic ketoacidosis or diabetic coma. Regular insulin is preferred in patients with poor tissue perfusion, shock, or cardiovascular collapse, or in patients requiring insulin for the treatment of severe, life-threatening hyperkalemia causing cardiotoxicity (*i.e.*, >8 mEq/L).

Pharmacology

Eliciting multiple biological responses, insulin initiates its actions by binding to cell-surface receptors, present in varying numbers in virtually all mammalian cells. This binding results in a cascade of intracellular events which can be studied in detail by consulting a physiology text.

Insulin is the primary hormone responsible for controlling the uptake, utilization, and storage of cellular nutrients. Insulin affects primarily liver, muscle, and adipose tissues, but also exerts potent regulatory effects on other cell types as well. Insulin stimulates carbohydrate metabolism in cardiac, skeletal, and adipose tissue by facilitating the uptake of glucose by these cells. Other tissues, such as brain, nerve, intestinal, liver, and kidney tubules, do not require insulin for glucose transport. Liver cells do need insulin to convert glucose to glycogen (for storage), and the hypothalamus requires insulin for glucose entry into the satiety center. Insulin has a direct effect on fat and protein metabolism. The hormone stimulates lipogenesis, increases protein synthesis, and inhibits lipolysis and free fatty acid release from adipose tissues. Insulin promotes an intracellular shift of potassium and magnesium. Exogenous insulin elicits all the pharmacologic responses usually produced by endogenous insulin.

Pharmacokinetics

Insulin is metabolized mainly by the liver and kidneys (also muscle and fat to a lesser degree) by enzymatic reduction to form peptides and amino acids. About 50% of the insulin that reaches the liver via the portal vein is destroyed and never reaches the general circulation. Insulin is filtered by the renal glomeruli and is reabsorbed by the tubules, which also degrade it. Severe impairment of renal function appears to affect the rate of clearance of circulating insulin to a greater extent than hepatic disease. Hepatic degradation of insulin operates near its maximal capacity and cannot compensate for diminished renal breakdown of the hormone. The half-life of endogenous insulin is less than ten minutes in normal subjects and in patients with uncomplicated diabetes.

Note: The pharmacokinetics of various insulin formulations can vary widely from published values between species, among individuals within a species, and within the same individual patient from day to day. Therefore, the values should only be used as a general reference guide.

Regular insulin injection: When the recombinant human insulin product is given IV to dogs and cats, it has an immediate onset of action, with maximum effects occurring at 0.5–2 hours; duration of action is 1–4 hours. Following IM administration, onset is 10–30 minutes; peak 1–4 hours; and duration 3–8 hours. After subcutaneous administration, onset is generally 10–30 minutes; peak from 1–5 hours; duration 4–10 hours.

Although the kinetics of all insulin products vary markedly for the individual product between species, regular insulin appears to exhibit the most similar properties.

Isophane insulin suspension (NPH): NPH is administered by the subcutaneous route only. Following SC administration of the recombinant human insulin product, onset is 0.5–2 hours in dogs and cats; peak is 2–10 hours in dogs and 2–8 hours in cats; and duration is 6–18 hours in dogs and 4–12 hours in cats.

Porcine insulin zinc suspension (Lente): Lente is classified as intermediate-acting; it has two peaks of activity following subcutaneous administration (the first at around 4 hours and the second at around 11 hours). The duration of activity varies between 14 and 24 hours. The peak(s), duration of activity, and dose required to adequately control diabetic signs will vary between dogs. Following SC administration of the recombinant human insulin lente product, onset is 0.5–2 hours in dogs and cats. Pharmacokinetics of the purified pork product are similar to the human product.

Protamine zinc suspension (PZI): Following SC administration, onset is 1–4 hours in dogs and cats; peak is 4–8 hours; duration is 6–28 hours in dogs; 6–24 hours in cats.

Insulin glargine injection: Following SC injection, the acidic solution is neutralized, and microprecipitates are formed which slowly release small amounts of insulin glargine. This action results in a relatively constant concentration/time profile over 24 hours with no pronounced peak in humans. A small Australian study compared equal doses of insulin glargine, PZI (mixed beef/pork), and purified pork lente insulin in 9 healthy cats. Results showed no significant difference in onset of action or nadir glucose concentrations among the insulins; time to reach nadir glucose concentration was longer for glargine (~16 hours) vs. PZI (~6 hours) and lente (~4.5 hours). Duration was significantly shorter for lente than for glargine or PZI, with glargine and PZI not significantly different. The study in healthy cats also showed there were definite peaks in insulin concentration and glucose lowering effects of glargine. (Marshall and Rand 2004)

Contraindications/Precautions/Warnings

Because there are no alternatives for insulin when it is used for diabetic indications, there are no absolute contraindications to its use. If animals develop hypersensitivity (local or otherwise) or should insulin resistance develop, a change in type or species of insulin should be tried. Pork insulin is identical to canine insulin and is considered the insulin source of choice for diabetic dogs. Human insulin has a low potential for producing insulin antibodies in dogs (~5%), while beef/pork insulin produces antibody formation in a higher percentage of dogs (~45%) and is associated with insulin resistance and poor or erratic glycemic control. Dogs known to have a systemic allergy to pork or pork products should not be treated with *Vetsulin*®. Beef/pork insulin is considered the source of choice in cats, although the incidence of insulin antibody production is low and approximately the same in cats treated with either beef/pork or human insulin. Overt insulin resistance caused by insulin antibodies occurs in less than 5% of cats treated with recombinant human insulin.

Do not inject insulin at the same site day after day or lipodystrophic reactions can occur.

Adverse Effects

Adverse effects of insulin therapy may include hypoglycemia (see overdose below), insulin-induced hyperglycemia (“Somogyi effect”), insulin antagonism/resistance, rapid insulin metabolism, and local reactions to the “foreign” proteins.

Reproductive/Nursing Safety

In humans, the FDA categorizes all human insulin and purified pork insulin as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In humans, the FDA categorizes insulin glargine as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Insulin is compatible with nursing.

Overdosage/Acute Toxicity

Overdosage of insulin can lead to various degrees of hypoglycemia. Signs may include weakness, shaking, head tilting, lethargy, ataxia, seizures, blindness, bizarre behavior, and coma. Other signs may include restlessness, hunger, and muscle fasciculations. Prolonged hypoglycemia can result in permanent brain damage or death.

Mild hypoglycemia may be treated by offering the animal its usual food. More serious symptoms (such as seizure) should be treated with oral dextrose solutions (e.g., *Karo*® syrup) rubbed on the oral mucosa (not poured down the throat) or by intravenous injections of 50% dextrose solutions (small amounts, slowly administered—usually 2–15 mL). If the animal is seizing, fingers should not be placed in the animal’s mouth. Once the animal’s hypoglycemia is alleviated (response usually occurs within 1–2 minutes), it should be closely monitored (both by physical observation and serial blood glucose levels) to prevent a recurrence of hypoglycemia (especially with the slower absorbed products) and to prevent hyperglycemia from developing. Future insulin dosages or feeding habits should be adjusted to prevent further occurrences of hypoglycemia.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving insulin and may be of significance in veterinary patients:

- **BETA-ADRENERGIC BLOCKERS** (e.g., **propranolol**): Can have variable effects on glycemic control and can mask the signs associated with hypoglycemia
- **CLONIDINE; RESERPINE**: Can mask the signs associated with hypoglycemia
- **DIGOXIN**: Because insulin can alter serum potassium levels, patients receiving concomitant cardiac glycoside (e.g., digoxin) therapy should be closely monitored; especially true in patients receiving concurrent diuretic therapy

The following drugs or drug classes may **potentiate the hypoglycemic activity of insulin**:

- **ALCOHOL**
- **ANABOLIC STEROIDS** (e.g., **stanozolol, boldenone**)
- **ANGIOTENSIN CONVERTING ENZYME INHIBITORS** (e.g., **captopril, enalapril**)
- **ASPIRIN or other salicylates**
- **DISOPYRAMIDE**
- **FLUOXETINE**
- **MONOAMINE OXIDASE INHIBITORS**
- **SOMATOSTATIN DERIVATIVES** (e.g., **octreotide**)
- **SULFONAMIDES**

The following drugs or drug classes may **decrease the hypoglycemic activity of insulin**:

- **CALCIUM CHANNEL BLOCKERS** (e.g., diltiazem)
- **CORTICOSTEROIDS**
- **DANAZOL**
- **DIURETICS**
- **ISONIAZID**
- **NIACIN**
- **PHENOTHIAZINES**
- **THYROID HORMONES** (can elevate blood glucose levels in diabetic patients when thyroid hormone therapy is first initiated)

Doses

Note: Treatment of diabetes mellitus and in particular, diabetic ketoacidosis is complex. Insulin is only one component of therapy; fluid and electrolytes, acid/base, and if necessary, antimicrobial therapy must also be employed. Adequate patient monitoring is mandatory. The reader is strongly encouraged to refer to more thorough discussions of treatment in veterinary endocrinology or internal medicine references for additional information.

■ DOGS:

For adjunctive therapy of diabetic ketoacidosis:

- a) Using Regular insulin, choose either the intermittent IM technique or low-dose IV infusion technique.

Intermittent IM technique: Initial Dose: 0.2 U/kg IM into muscles of the rear legs; repeat IM doses of 0.1 U/kg hourly. Initial doses may be reduced by 25–50% in animals with severe hypokalemia. Goal is to slowly lower blood glucose to 200–250 mg/dL over a 6–10 hour period. As blood glucose approaches 250 mg/dL, switch to IM regular insulin at 0.1–0.4 U/kg q4–6h or subcutaneous (if hydration status is good) q6–8h. Goal is to keep blood glucose in the 150–300 mg/dL range. Giving 5% dextrose IV is necessary during this stage.

Constant Low-Dose Infusion Technique: Initially give regular insulin at a rate of 0.05–0.1 U/kg/hr in an IV line separate from that for fluid therapy. Initial doses may be reduced by 25–50% in animals with severe hypokalemia. Adjust infusion rate based upon hourly blood glucose determinations. An hourly reduction in blood glucose by 50–100 mg/dL is ideal. Once blood glucose approaches 250 mg/dL switch to IM regular insulin every 4–6 hours or to subcutaneous regular insulin at 0.1–0.4 U/kg q6–8h if hydration status is good. Goal is to keep blood glucose in the 150–300 mg/dL range. Giving 5% dextrose IV is necessary during this stage. Alternatively, may continue IV infusion at a decreased rate until exchanged for a longer-acting product. (Nelson and Elliott 2003a)

For adjunctive treatment of severe hyperkalemia (>8 mEq/L):

- a) Give *regular insulin* 0.25–0.5 U/kg slow IV bolus followed by 50% dextrose (4 mL/U of administered insulin); or give regular 0.5–1 U/kg in parenteral fluids plus 2 grams dextrose per unit insulin administered (Nelson and Elliott 2003b)

Insulin treatment of uncomplicated diabetes mellitus:

- a) *Vetsulin*®: The initial recommended dose is 1 U insulin/kg body weight plus a body weight-dependent dose supplement (as shown in the table below) given SC once daily concurrently with, or right after a meal. Re-evaluation of the patient should be performed at appropriate intervals and insulin doses adjusted as needed. (*Vetsulin*® package insert)

DOSE	DOSE PLUS	DOSE SUPPLEMENT	INITIAL DOSE
<10 kg	(Weight in kg) x 1 U/kg	1 Unit	1 U/kg + 1 Unit
10–11 kg	(Weight in kg) x 1 U/kg	2 Units	1 U/kg + 2 Units
12–20 kg	(Weight in kg) x 1 U/kg	3 Units	1 U/kg + 3 Units
>20 kg	(Weight in kg) x 1 U/kg	4 Units	1 U/kg + 4 Units

Twice daily dosing may be required if the duration of action is insufficient. To calculate the twice daily dose, decrease the total once daily dose by 25% and give that calculated dose twice daily. For example, the new dose for a dog previously receiving 20 Units once daily would be 15 Units twice daily. (Intervet; Technical Services)

- b) *NPH insulin of recombinant human origin*: give 0.25 U/kg SC every 12 hours. (Nelson 2007)

Note: More than 90% of dogs will require twice daily doses of intermediate acting insulin; therefore, initiating therapy with this regimen may result in better and easier glycemic control and fewer problems with hypoglycemia and the Somogyi effect). Dietary therapy is used concurrently. Following stabilization, diabetic dogs are typically evaluated every 7 days until an effective insulin protocol is established. (Nelson and Elliott 2003a)

- c) *Insulin glargine*: Initiate dose of insulin glargine at 0.25 U/kg SC q12 hours in dogs with poor response to porcine zinc insulin or NPH. (Nelson 2007)

■ CATS:

For adjunctive therapy of diabetic ketoacidosis:

- a) Use the same protocol as described above in “a” for dogs (Nelson and Elliott 2003a)

Insulin treatment of uncomplicated diabetes mellitus:

Note: Cats are very unpredictable in their response to insulin therapy, and no single type of insulin is routinely effective in maintaining glycemic control, even with twice daily dosing. Cats should be closely monitored during the first month of insulin therapy.

- a) *Using PZI*: Starting dose: 0.1–0.3 Units per pound body weight (0.22–0.6 Units/kg) SC every 12 to 24 hours (maximum starting dose should not exceed 3 total Units per cat every 12 hours); reevaluate every 7–14 days and adjust insulin dose as necessary to achieve regulation (*PZI-VET* product information)
- b) *Using PZI*: Starting dose: 1 Unit per cat SC every 12 hours (Nelson 2007)
- c) *Using Porcine insulin zinc (lente)*: Starting dose: 1–2 Units per cat SC every 12 hours. Half of the cat's total daily caloric intake should be offered at the time of each insulin injection, and the cat should have access to any uneaten food until time for the next injection. Patients should be evaluated at appropriate intervals and insulin dose adjustments made accordingly. (Nelson and Elliott 2003a)
- d) *Using Porcine insulin zinc (lente)*: Starting dose: 0.25 U/kg twice daily if the blood glucose concentration is between 216–342 mg/dL and 0.5 U/kg twice daily if the blood glucose concentration is >360 mg/dL. (Rand 1997, Behrend 2007)

- e) *Using Porcine insulin zinc (lente)*: Starting dose: 1 Unit/cat twice daily for cats weighing less than 4 kg and 1.5–2 Unit/cat twice daily for cats weighing >4 kg can be used to initiate therapy (Reusch 2005, Behrend 2007)
- f) *Using NPH*: Starting dose: 0.5 U/kg SC every 12 hours. (Boothe 2001)
- g) *Using NPH*: Starting dose: 1–2 Units per cat SC every 12 hours (Cohn, Graves 2007)
- h) *Using Insulin glargine (Lantus)*: 1 Unit per cat SC every 24 hours; increase to twice daily injections if subsequent blood glucose evaluations indicate less than 12 hours duration. (Nelson 2007)
- i) *Using Insulin glargine (Lantus)*: 0.25–0.5 U/kg SC every 12 hours, not to exceed 3 Units per cat q12 hours starting dose (Peterson, Kintzer 2007)

Note: insulin glargine may have little or no effect on blood glucose in cats for the first 3 days after initiation of therapy. Dose increases are not recommended for the first week of therapy to avoid possible hypoglycemia. Some cats may require a decrease in dose, and some may achieve diabetic remission after one month of glargine therapy.

■ BIRDS:

Diabetes mellitus is most common in budgies, cockatiels, and toucans. Blood glucose levels in diabetic birds range from 600–2000 mg/dL (Definitive diagnosis requires persistently elevated blood glucose levels >800 mg/dL). Insulin therapy is sometimes hindered by the highly variable dose needed for individual birds, the development of insulin resistance, and the development of pancreatic atrophy and pancreatic insufficiency.

- a) Insulin dose: Initially, 0.1–0.2 U/kg regular insulin. When stabilized, NPH insulin can be started. Dose range is 0.067–3.3 U/kg IM every 12–24 hours. (Oglesbee 2003) A blood glucose curve should be obtained. Determine blood glucose levels initially, then every 2–3 hours for 12–24 hours. The dose is adjusted based on blood glucose levels. Frequency varies from twice daily to once every several days. Bird should be placed on a low-carbohydrate diet. Clinical sign of successful treatment is weight gain. Monitor for hypoglycemia. Treat hypoglycemia with oral or injectable dextrose or oral corn syrup. (Rupley 1997)

■ FERRETS:

Treatment of diabetes mellitus:

- a) NPH 0.5–1 Unit per ferret SC twice daily. Goal of therapy is negative ketones and a small amount of glucose in the urine. (Quesenberry and Carpenter 2003)
- b) NPH 0.1–0.5 IU/kg IM or SC twice daily to start; adjust to optimal dose. May require insulin to be diluted; monitor urine for glucose/ketones. (Williams 2000)

■ CATTLE:

For adjunctive treatment of ketosis:

- a) PZI insulin 200 Units (total dose) SC once every 48 hours (Smith 2002a)

■ HORSES:

For diabetes mellitus:

- a) True diabetes mellitus rarely occurs in horses. Most cases are a result of pituitary tumors that cause hyperglycemia secondary to excessive ACTH or growth hormone. A case is cited where an animal received 0.5–1 Unit/kg of PZI insulin and the hyperglycemia was controlled. Patients with hyperglycemia secondary to a pituitary tumor are apparently insulin-resistant (Merritt 1987).

- b) PZI insulin 0.15 U/kg IM or SC twice daily (Robinson 1987)
- For treatment of hyperlipemia in ponies:

- a) For a 200 kg pony: PZI 30 U (total dose) IM every 12 hours on odd days (given with 100 grams glucose orally once daily); PZI 15 U (total dose) IM every 12 hours on even days (given with 100 grams galactose orally once daily) until hyperlipemia resolves. (Smith 2002a)

Monitoring Parameters

- Blood glucose
- Patient weight, appetite, fluid intake/output
- Blood, urine ketones (if warranted)
- Glycosylated hemoglobin and fructosamine [goal = fructosamine <450 micromol/L] (if available and warranted)

Client Information

- Keep insulin products away from temperature extremes. If stored in the refrigerator, allow to come to room temperature in syringe before injecting.
- Clients must be instructed in proper techniques for withdrawing insulin into the syringe, including rolling the vial, not shaking before withdrawing into syringe, and using the proper syringe size with insulin concentration (*e.g.*, not confusing U-40 insulin/syringes with U-100 insulin/syringes).
- Proper injection techniques should be taught and practiced with the client before the animal's discharge.
- The symptoms of hypoglycemia should be thoroughly reviewed with the owner.
- A written protocol outlining monitoring procedures and treatment steps for hypoglycemia should be sent home with the owner.
- When traveling, insulin should not be left in carry-on luggage that will pass through airport surveillance equipment. Generally, insulin stability is not affected by a single pass through surveillance equipment; however, longer than normal exposure or repeated passes through surveillance equipment may alter insulin potency.

Chemistry and Biosynthesis

The endocrine component of the pancreas is organized as discrete islets (islets of Langerhans) that contain four cell types, each of which produces a different hormone. Insulin is produced in the beta cells, which comprise 60–80% of the islet. Insulin is a protein consisting of two chains, designated A and B, with 21 and 30 amino acids respectively that are connected by two disulfide bonds. The amino acid composition of insulin has been determined in various species of animals. The insulin of dogs, pigs, and certain whales (sperm and fin) is identical in structure; sheep insulin is identical to goat. Cattle, sheep, horses, and dogs differ only in positions 8, 9, and 10 of the A chain. Porcine insulin differs from human insulin by one amino acid [alanine instead of threonine at the carboxy terminal of the B chain (*i.e.*, in position B 30)], and bovine insulin differs by two additional alterations in the A chain (threonine and isoleucine in positions A8 and A10 are replaced by alanine and valine, respectively). Of the domestic species, feline insulin is most similar to bovine insulin, differing by only 1 amino acid (at position 18 of the A chain). Human insulin differs from rabbit insulin by a single amino acid. There is a single insulin gene and a single protein product in most mammalian species (multiple insulins appear to occur frequently among fishes).

For therapeutic purposes, doses and concentrations of insulin are expressed in Units (U). One unit of insulin is equal to the amount required to reduce the concentration of blood glucose in a fasting rabbit to 45 mg/dl (2.5 mM). All commercial preparations

of human insulin currently manufactured in the U.S. are supplied in solution or suspension at a concentration of 100 U/mL, which is approximately 3.6 mg of insulin per milliliter; likewise, one unit of insulin equals about 36 micrograms of insulin.

Insulin is a small protein; human insulin has a molecular weight of 5808. Insulin secretion is a tightly regulated process designed to provide stable concentrations of glucose in blood during fasting and feeding. This regulation is achieved by the coordinated interplay of various nutrients, gastrointestinal and pancreatic hormones, and autonomic neurotransmitters. The primary stimulus for secretion of endogenous insulin is glucose.

Regular insulin is a rapid-acting sterile solution prepared by precipitating insulin in the presence of zinc chloride to form zinc insulin crystals. Regular insulin 100 U/mL is a clear and colorless or almost colorless solution. Discoloration, turbidity, or unusual viscosity indicates deterioration or contamination.

Isophane insulin, more commonly known as *NPH*, is an intermediate-acting, sterile suspension of zinc insulin crystals and protamine sulfate in buffered water for injection.

Porcine Lente insulin is a sterile aqueous suspension of purified pork Lente insulin consisting of 30% amorphous zinc insulin and 70% crystalline zinc insulin. It is available only as a U-40 insulin concentration and is a cloudy or milky suspension of a mixture of characteristic crystals and particles with no uniform shape.

Protamine zinc suspension (PZI) is composed of 90% beef/10% pork insulin combined with zinc and protamine (a protein extracted from salmon testes), which slow the release of the insulin into tissues. PZI is clear (not cloudy) with white sediment (no clumps), that when mixed gently, looks like watery milk. It is available only as a U-40 insulin concentration.

Insulin glargine is a long-acting human insulin analog produced by recombinant DNA technology utilizing a non-pathogenic laboratory strain of *E. coli*. It differs from human insulin in that the amino acid asparagine at position A21 is replaced by glycine, and two arginines are added to the C-terminus of the B chain. The injection consists of insulin glargine dissolved in a clear aqueous fluid. It is available only as a U-100 insulin concentration.

All human, purified pork, and beef/pork insulin products have a neutral pH of approximately 7–7.8, while insulin glargine has an acidic pH of approximately 4.

Stability/Storage/Compatibility

Manufacturers of insulin recommend that all insulin products be stored in the refrigerator but protected from freezing temperatures (do not store at temperatures $<36^{\circ}\text{F}$ or $<2^{\circ}\text{C}$). Freezing may alter the protein structure, decreasing potency. Particle aggregation and crystal damage may be visible to the naked eye or may require microscopic examination. Higher temperature ($>86^{\circ}\text{F}$ or $>30^{\circ}\text{C}$) extremes and direct exposure to sunlight should be avoided (such as might occur when insulin is stored in a car glove compartment or on a window sill), since insulin transformation products and fibril formation may occur. Although the manufacturers recommend a maximum of 30 days storage at room temperature, studies have actually shown that regular insulin maintains stability of 24–30 months at 25°C . One study showed a 5% loss of biological potency after about 36 months at 25°C .

According to the manufacturer's label, insulin glargine has a discard date of 28 days after the initial puncture of the vial (consistent with all human-labeled insulin products) and stored at room temperature, although clinical reports indicate that opened vials stored in the refrigerator can be used for up to 6 months; discard vial immediately if there is any discoloration. Bacterial contamination and precipitation associated with pH change can cause cloudiness (Marshall and Rand 2006).

For animals requiring small doses of glargine, the 3 mL cartridge may be preferable to the 10 mL vial to prevent the need for extended use beyond the recommended discard date.

Flocculation of NPH human insulin may appear 3–6 weeks after opening the vial. Deterioration in glycemic control may appear before frosting of the vial. If unexplained hyperglycemia is observed, a new vial of insulin should be used.

Regular and NPH insulin may be stored in plastic or glass syringes under refrigeration for 5–7 days without loss of potency. One study found no degradation after 14 days storage under refrigeration. Other sources state that prefilled insulin syringes are stable for 30 days when stored in the refrigerator. It is generally accepted that syringes of insulin can be stored for 28 days under refrigeration without fear of potency loss.

Regular insulin is reportedly physically **compatible** with following drugs/solutions: normal saline, TPN solutions (4% amino acids, 25% dextrose with electrolytes and vitamins; must occasionally shake bag to prevent separation), bretylium tosylate, cimetidine HCl, lidocaine HCl, oxytetracycline HCl, and verapamil HCl. Regular insulin may be mixed with other insulin products (except for glargine) used in veterinary medicine (e.g., NPH, PZI, etc.).

Regular insulin is reportedly physically **incompatible** when mixed with the following drugs/solutions: aminophylline, amobarbital sodium, chlorothiazide sodium, cytarabine, dobutamine HCl, nitrofurantoin sodium, pentobarbital sodium, phenobarbital sodium, phenytoin sodium, secobarbital sodium, sodium bicarbonate, sulfisoxazole sodium, and thiopental sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

Diluting insulin: Other than for immediate use, insulin should only be diluted using product-specific sterile diluents supplied by the manufacturer. Diluents for Regular insulin (*Humulin R*) and NPH insulin (*Humulin N*) and sterile vials can be obtained by telephoning the manufacturer. Diluted insulin is stable for 4 (preferred) to 6 weeks and should be stored in the refrigerator. For immediate use, insulin products (except glargine) can be diluted with normal saline for injection, but the potency cannot be predicted after 24 hours. **Insulin glargine must not be diluted or mixed** with any other insulin or solution because the prolonged action is dependent on its pH.

Adsorption: The adsorption of regular insulin to the surfaces of IV infusion solution containers, glass and plastic (including PVC, ethylene vinyl acetate, polyethylene, and other polyolefins), tubing, and filters has been demonstrated. Estimates of loss of potency range from 20–80%, although reports of 20–30% are more common. The percent adsorbed is inversely proportional to the concentration of the insulin, and may include other factors such as the amount of container surface area, the fill volume of the solution, the type of solution, type and length of administration set, temperature, previous exposure of tubing to insulin, and the presence of other drugs, blood, etc. The adsorption process is instantaneous, with the bulk of insulin adsorption occurring within the first 30–60 minutes. To saturate binding sites and deliver a more predictable dose to the patient through an IV infusion, it is recommended that the first 50 mL be run through the IV tubing and discarded.

Insulin Syringes: Syringes are designed for use with a specific strength of insulin, with the needle covers color-coded according to strength. U-40 syringes have a red top, while U-100 syringes have an orange top. U-40 syringes contain $\frac{1}{2}$ cc (equivalent to 0.5 mL) and have 20 unit marks. Measuring U-40 insulin to the one unit mark in a U-40 syringe will contain 1U of insulin. U-100 syringes are available in 3/10cc, $\frac{1}{2}$ cc, and 1cc size. Measuring U-100 insulin to one mark in a U-100 syringe will contain 1U of insulin.

Tuberculin syringes can also be used, but are not generally recommended because the potential for confusion is substantial. If using 100U/mL or TB syringes to measure 40U/mL insulin doses:

- Determine the required dose in units.
- If using U-100 insulin syringes (orange top), multiply the required Units of U-40 insulin by 2.5 (e.g. If required dose is 10 units, $10 \times 2.5 = 25$ units).
- If using TB syringes, multiply the required Units of U-40 insulin $\times 0.025$ (e.g., If the required dose is 10 Units, $10 \times 0.025 = 0.25$ mL).

Reuse of Insulin Syringes: Reuse of disposable insulin syringes has been suggested to reduce client costs. However, disposable insulin syringes are usually siliconized, and reuse can result in contamination of vials of insulin with silicone oil, causing a white precipitate and impairment of biological effects.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Porcine insulin zinc suspension 40 U/mL in 10 mL vials, intermediate-acting; *Vetsulin*® (Intervet) in U.S.; *Caninsulin*® (Intervet) in Canada & Europe; (Rx). FDA approved for use in dogs.

Protamine zinc insulin (beef 90%/pork 10%) 40 U/mL in 10 mL vials; long-acting; *PZI VET*® (IDEXX); (Rx). Not fully FDA approved, but distribution is allowed under the Medically Necessary Veterinary Products Policy for use in cats.

HUMAN-LABELED PRODUCTS:

Note: partial listing; includes only those products generally used in veterinary medicine.

Insulin Injection, Regular — (short-acting):

Human (rDNA): 100 U/mL in 10 mL vials; *Humulin*® R (Eli Lilly); *Novolin*® R & *Novolin*® R® Prefilled (Novo Nordisk); (OTC)

Isothane (Neutral Protamine Hagedorn; NPH) — (intermediate-acting):

Human (rDNA) 100 U/mL in 10 mL vials, 5 x 1.5 mL prefilled syringes & 5 x 3 mL pen insulin delivery devices; *Humulin*® N (Lilly); *Novolin*® N & *Prefilled* (Novo Nordisk); (OTC)

Human (rDNA) Cartridges (suspension) 100 U/mL in 5 x 1.5 mL & 5 x 3 mL; *Novolin*® N® PenFill (Novo Nordisk); (OTC)

Combination: Insulin Isothane & Regular Injection (suspension):

Human (rDNA) 100 U/mL 70% isophane insulin (NPH) & 30 % insulin injection (regular) in 5 x 3 mL disposable pen insulin delivery devices, 10 mL vials & 5 x 1.5 mL prefilled syringes; *Humulin*® 70/30 (Lilly); *Novolin*® 70/30 & *Prefilled* (Novo Nordisk); (OTC)

Human (rDNA) Cartridges (suspension): 100 U/mL; 70% isophane insulin (NPH) & 30% insulin injection (regular) in 5 x 1.5 & 5 x 3 mL; *Novolin*® 70/30 PenFill (Novo Nordisk); (OTC)

Human (rDNA) Injection (suspension): 100 U/mL; 50% isophane insulin (NPH) & 50% insulin injection (regular) in 10 mL vials; *Humulin*® 50/50 (Lilly); (OTC)

Insulin Glargine Injection—(long-acting):

Human (rDNA) 100 U/mL in 10 mL vials & 3 mL cartridge system for use with *OptiClik*; *Lantus*® (Aventis); (Rx)

INTERFERON ALFA, HUMAN RECOMBINANT

(in-ter-feer-on) Roferon-A®, Intron-A®

IMMUNOMODULATOR

Prescriber Highlights

- Cytokine used to alleviate clinical effects of certain viral diseases; little scientific info available to document safety/efficacy in small animals
- Cautions: Preexisting autoimmune disease, severe cardiac disease, pulmonary disease, “brittle” diabetes, Herpes infections, hypersensitivity to the drug, or CNS disorders
- Adverse Effects: In cats, adverse effects are apparently uncommon with PO; higher dosages given parenterally may cause malaise; fever, allergic reactions, myelotoxicity & myalgia are possible

Uses/Indications

Interferon alfa use in veterinary medicine in the past has primarily been centered on its oral/buccal administration in cats to treat non-neoplastic FeLV disease. Oral interferon may also be of benefit in the treatment of ocular herpes infection.

Feline interferon-omega has recently become available in several countries and it may be found significantly useful in treating viral diseases in both cats and dogs. A separate monograph for this agent, follows this one.

Pharmacology/Actions

The pharmacologic effects of the interferons are widespread and complex. Suffice it to say, that interferon alfa has antiviral, antiproliferative, and immunomodulating effects. Its antiproliferative and antiviral activities are thought to be due to its effects on the synthesis of RNA, DNA, and cellular proteins (oncogenes included). The mechanisms for its antineoplastic activities are not well understood, but are probably related these effects as well.

Pharmacokinetics

Interferon alfa is poorly absorbed after oral administration due to its degradation by proteolytic enzymes and studies have not detected measurable levels in the systemic circulation, however, there may be some absorption via upper GI mucosa.

Interferon alfa is widely distributed throughout the body, although it does not penetrate into the CNS well. It is unknown if it crosses the placenta. Interferon alfa is freely filtered by the glomeruli, but is absorbed by the renal tubules where it is metabolized by brush border or lysosomes. Hepatic metabolism is of minor importance. The plasma half-life in cats has been reported as 2.9 hours.

Contraindications/Precautions/Warnings

When used parenterally, consider the risks versus benefits in patients with preexisting autoimmune disease, severe cardiac disease, pulmonary disease, “brittle” diabetes, Herpes infections, hypersensitivity to the drug, or CNS disorders.

Adverse Effects

When used orally in cats, adverse effects are apparently uncommon. Higher dosages given parenterally to cats may cause malaise; fever, allergic reactions, myelotoxicity, and myalgia are possible. Cats given human interferon-alfa parenterally may develop significant antibodies to it after 7–8 weeks of treatment. When used systemi-

cally in humans, adverse effects have included anemia, leukopenias, thrombocytopenia, hepatotoxicity, neurotoxicity, taste sensation changes, anorexia, nausea, vomiting, diarrhea, dizziness, “flu-like” syndrome, transient hypotension, skin rashes, and dry mouth. Except for the “flu-like” syndrome, most adverse effects are dose-related and may vary depending on the condition treated.

Reproductive/Nursing Safety

Safety during pregnancy has not been established; high parenteral doses in monkeys did not cause teratogenic effects, but did increase abortifacient activity. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in milk.

Overdosage/Acute Toxicity

No information was located. Determine dosages carefully.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving interferon and may be of significance in veterinary patients:

- **ACYCLOVIR, ZIDOVUDINE, VIDARABINE:** Additive or synergistic antiviral effects may occur when interferon alfa is used in conjunction with zidovudine (AZT) or acyclovir. This effect does not appear to occur with vidarabine, although increased toxicities may occur. The veterinary significance of these potential interactions is unclear.

Doses

■ DOGS:

For cutaneous T-cell lymphoma and severe cases of oral/cutaneous papillomas:

- a) 1.5–2 million units/m² SC 3 times weekly (White 2000)

For immunosuppression:

- a) 1 Unit/5 kg PO once daily for 7 days. Treat alternate weeks or continuously. (Greene and Watson 1998)

■ CATS:

For indolent lip ulcers:

- a) 60–120 Units PO or SC daily (White 2000)

For treatment of FeLV-infected cats:

- a) Low dose: 30 U cat PO daily; 7 days on, 7 days off; Hi dose: 10,000–1,000,000 U/kg SC once daily. Little in the way of large, controlled trials to determine which, if any, immunomodulating therapies (interferon or other agents) are likely to benefit FeLV-infected cats. (Levy 2004)

For treatment of FIV-infected cats:

- a) 30 U cat PO daily; 7 days on, 7 days off (Barr and Phillips 2000)

For adjunctive treatment of FHV-1-infected cats:

- a) For chronic infections: 30 U cat PO daily; 7 days on, 7 days off; repeat cycle. May also use topical ophthalmic therapy: one drop of 25–50 IU/mL of saline in affected eye(s) q4–6 hours. (Powell 2002)
- b) For acute life-threatening infections in kittens: 10,000 IU/kg SC daily for up to 3 weeks (Lappin 2003b)

For treatment of FIP-infected cats:

- a) For exudative form (wet): 20,000 U/cat IM once daily for 14–21 days. For nonexudative form (dry): 30 U/cat PO once daily for 7 days. Treat alternate weeks. (Greene and Watson 1998)

To prepare a 3 U/mL solution for oral administration: Using the 3 million IU vial (see below), dilute the entire contents into 100 mL of sterile water; mix well. Resulting solution contains approximately 30,000 IU/mL. Take 0.1 mL of this solution and add to one liter of sterile saline that has 4 mL of 25% albumin added to it. Albumin is optional but adds stability. Solution is now 3 U/mL. Divide into aliquots of 15 mL and freeze, preferably at –70°C. Thaw as needed and keep refrigerated. Discard unused portion after 60 days. Discard unused 30,000 U/mL solution within 2–3 hours of making initial dilutions.

Preparation of solution for 30 U/mL oral administration: Using the 3 million IU vial (see below), dilute the entire contents into a 1 L bag of sterile normal saline; mix well. Resulting solution contains approximately 3,000 IU/mL. Divide into aliquots of either 1 or 10 mL and freeze. By diluting further 100 fold (1 mL of 3000 IU/mL solution with 100 mL of sterile saline, or 10 mL with 1000 mL of sterile saline) a 30 IU/mL solution will result. Some have advised aliquoting the diluted solution into 1 mL volumes for freezing up to a year; defrost as necessary. Once defrosted, the drug can be refrigerated up to one week. Freezing the most dilute solutions is associated with loss in activity unless protein such as albumin (see above) is added during dilution. (Greene, Hartmann et al. 2006)

Client Information

- Owners should be made aware of the “investigational” nature of this compound and understand that efficacy and safety have not necessarily been established.

Chemistry/Synonyms

Prepared from genetically engineered cultures of *E. coli* with genes from human leukocytes, interferon alfa-2a is commercially available as a sterile solution or sterile powder. Human interferon alfa is a complex protein that contains 165 or 166 amino acids.

Interferon may also be known as: IFN-alpha, interferon-alpha, Ro-22-8181 (interferon alfa-2a), Sch-30500 (interferon alfa-2b); there are many internationally registered trade names available.

Storage/Stability/Compatibility

Commercially available products should be stored in the refrigerator; do not freeze the accompanying diluent. Do not expose solutions to room temperature for longer than 24 hours. Do not vigorously shake solutions.

An article proposing using this product in cats for the treatment of FeLV states that after dilution of 3 million IU in one liter of sterile saline the resultant solution remains active for years if frozen or for months if refrigerated. However, data corroborating this is apparently not available.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Interferon Alfa-2a (recombinant rIFN-A; IFLrA) Injection: Prefilled syringes: 3 million I.U./syringe (0.5 mL single-use syringes); 6 million I.U./syringe (0.5 mL single-use syringes); 9 million I.U./syringe (0.5 mL single-use syringes); *Roferon-A*® (Hoffman La-Roche); (Rx)

Interferon Alfa-2b (recombinant (IFN-alpha2; rIFN-a2; a-2-interferon) Powder for Injection: 5 million IU/vial; 10 million IU/vial; 18 million IU/vial; 25 million IU/vial & 50 million IU/vial in vials with a mL, 2 mL or 5 mL diluent/vial; *Intron A*® (Schering); (Rx)

Interferon Alfa-2b (recombinant (IFN- α 2; rIFN- α 2; a-2-interferon) Injection: 3 million IU/dose; 5 million IU/dose, & 10 million IU/dose in multidose pens; *Intron A*® (Schering); (Rx)

Interferon Alfa-2b (recombinant (IFN- α 2; rIFN- α 2; a-2-interferon) Solution for Injection: 3 million IU/vial, 5 million IU/vial; 10 million IU/vial; 18 million IU/vial & 25 million IU/vial in vials, Pak-3, -5, -10 (vials & syringes); & in multidose vials (22.8 million IU/3.8 mL/vial or 32 million IU/3.2 mL/vial); *Intron A*® (Schering); (Rx)

Interferon Alfa-N3 (human leukocyte derived) Injection: 5 million IU/mL (8 mg NaCl, 1.74 mg Na phosphate dibasic, 0.2 mg K phosphate monobasic, 0.2 mg KCl) in 1 mL vials; *Alferon N*® (Interferon Sciences Inc.); (Rx)

INTERFERON- Ω (OMEGA)

(in-ter-feer-on oh-may-ga) Virbagen Omega®, Recombinant Omega Interferon of Feline Origin, rFeIFN-Omega

IMMUNOMODULATOR

Prescriber Highlights

- ▶ Immunomodulating cytokine labeled for treating FeLV & FIV in cats & Parvo in dogs; not commercially available in USA
- ▶ Appears to be well tolerated; adverse effects include: hyperthermia, vomiting, diarrhea (cats), fatigue (cats)
- ▶ Increases in ALT & decreases in RBC, WBC, & platelet counts have been seen
- ▶ Treatment may be very expensive

Uses/Indications

Omega interferon (feline) is labeled (in the EU) for dogs 1 month of age or older for the reduction in mortality and clinical signs of parvovirus (enteric form). In cats 9 weeks of age or older, it is labeled for treating FeLV and/or FIV, in non-terminal clinical stages. It may be of benefit in treating canine distemper, acute feline calicivirus infections, FIP, or topically for feline herpetic keratitis, but data is still being gathered to document efficacy.

Pharmacology/Actions

Omega interferon is a type 1 interferon related to alpha interferon. Its principle action is not as a direct anti-viral, but by acting on virus-infected cells inhibiting mRNA and translation proteins thereby inhibiting viral replication. It may also nonspecifically enhance immune defense mechanisms.

Pharmacokinetics

It has been stated that omega interferon pharmacokinetics in dogs and cats is similar to that of human interferons. After intravenous injection, omega interferon is rapidly bound to specific receptor sites on a variety of cells. Highest tissue levels are found in the liver and kidneys. Interferon is filtered in the renal glomeruli and catabolized in the kidneys. In dogs, volume of distribution at steady state is about 0.1L/kg. Biphasic elimination occurs with an alpha half-life of 3.14 hours and a beta half-life of 0.24 hours. Total body clearance is 6.9 mL/min/kg.

Contraindications/Precautions/Warnings

The manufacturer cautions against vaccinating dogs currently being treated with omega interferon and not to vaccinate until the

patient appears to have recovered. As both FeLV and FIV infections are known to be immunosuppressive, the manufacturer states that cat vaccinations are contraindicated during and after omega interferon treatment.

There are several different interferons available for use in humans (several sub-types of alpha, beta, or gamma interferon); one cannot be substituted for another.

Adverse Effects

In cats and dogs, hyperthermia (3–6 hours post-dose) and vomiting have been reported. Slight decreases in RBCs, platelets and WBCs, and increased ALT have been observed but, reportedly, these indices return to normal within a week of the last injection.

Additionally, soft feces/mild diarrhea and transient fatigue may be noted in cats. Intravenous administration to cats may cause increased incidence and severity of adverse effects.

Dogs may develop antibodies to interferon omega if treatment is prolonged (beyond labeled dosage period) or repeated.

Reproductive/Nursing Safety

Safety during pregnancy or lactation has not been established.

Overdosage/Acute Toxicity

10X overdoses in dogs and cats caused mild lethargy/somnolence, slight hyperthermia, slight increases in respiratory and heart rates. In animals tested, signs resolved within 7 days and no treatment was required.

Drug Interactions

No reported drug interactions at the time of writing, but use caution when using other drugs that can be hepatotoxic or myelosuppressive.

Laboratory Considerations

No specific concerns were noted

Doses

■ DOGS:

- a) For treatment of parvovirus as labeled: 2.5 million Units/kg IV once daily for 3 days. The earlier the dog is treated, the more likely of success. (Label information; *Virbagen Omega*®—Virbac UK)

■ CATS:

- a) For treatment of FeLV or FV as labeled: 1 million Units/kg SC once daily for 5 days. Three separate 5-day treatments performed at day 0, day 14, and day 60. (Label information; *Virbagen Omega*®—Virbac UK)

Monitoring

- Monitor for efficacy for infection treated
- CBC and hepatic function tests suggested

Client Information

- This drug is best administered on an inpatient basis where the patient may be observed and supported

Chemistry/Synonyms

Interferon omega of feline origin is a type 1 recombinant interferon obtained from silkworms after inoculation with a recombinant baculovirus. It is provided commercially as a lyophilisate powder with a separate solvent.

Recombinant omega interferon of feline origin may also be known as: Interferon omega, omega interferon, interferon- ω , IFN- ω , IFN- ω (feline recombinant), rFeIFN- ω , and *Virbagen Omega*®.

Storage/Stability/Compatibility

The commercial veterinary product should be stored in its original carton refrigerated ($4^{\circ}\text{C} \pm 2^{\circ}\text{C}$) and protected from freezing. It has a designated shelf life of 2 years when properly stored. Once reconstituted with the supplied isotonic sodium chloride solution, it should be used immediately as it contains no preservative, however, the solution is reported to be stable for at least 3 weeks when refrigerated. No data was located on the stability of the reconstituted solution when frozen. The manufacturer states: Do not mix with any other vaccine/immunological product, except the solvent supplied for use with the product.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None in the USA

In the EU:

Recombinant Omega Interferon of Feline Origin 10 million Units/vial; *Virbagen Omega*® (Virbac); (Rx). Approved for dogs and cats. A 5 million Unit vial may be available in some countries.

The FDA may allow legal importation into the USA of this medication for compassionate use in animals; for more information, see the *Instructions for Legally Importing Drugs for Compassionate Use in the USA* found in the appendix.

HUMAN-LABELED PRODUCTS: None

IODIDE, SODIUM IODIDE, POTASSIUM

(eye-oh-dide) SSKI, Iodoject®

ANTIFUNGAL, NUTRITIONAL

Prescriber Highlights

- ▶ Iodides used for actinobacillosis in ruminants, sporotrichosis in horses, dogs, & cats
- ▶ Contraindications: Iodide hypersensitivity, lactating animals, hyperthyroidism, renal failure, or dehydration
- ▶ Do not inject IM; give IV slowly & with caution to horses as severe generalized reactions have been reported
- ▶ May cause abortion in cattle
- ▶ Adverse Effects: Iodism: Excessive tearing, vomiting, anorexia nasal discharge, muscle twitching, cardiomyopathy, scaly haircoats/dandruff, hyperthermia, decreased milk production & weight gain, coughing, inappetence, & diarrhea
- ▶ Cats more prone to developing toxicity

Uses/Indications

The primary use for sodium iodide is in the treatment of actinobacillosis and actinomycosis in cattle. It has been used as an expectorant with little success in a variety of species and occasionally as a supplement for iodine deficiency disorders. In horses, dogs and cats, oral sodium or potassium iodide has been used in the treatment of sporotrichosis. Use in cats is controversial as they may be prone to developing adverse effects; cats may require other antifungal (e.g., itraconazole) therapy. Potassium iodide has also been used as an expectorant, but documentation of efficacy is lacking.

Pharmacology/Actions

While the exact mode of action for its efficacy in treating actinobacillosis is unknown, iodides probably have some effect on the gran-

ulomatous inflammatory process. Iodides have little, if any, *in vitro* antibiotic activity.

Pharmacokinetics

Little published information appears to be available. Therapeutic efficacy of intravenous sodium iodide for actinobacillosis is rapid, with beneficial effects usually seen within 48 hours of therapy.

Contraindications/Precautions/Warnings

Sodium iodide injection labels state that it should not be given to lactating animals or to animals with hyperthyroidism. Do not inject intramuscularly (IM).

Iodides given parenterally should be administered slowly intravenously and with caution to horses; severe generalized reactions have been reported.

Should not be used in animals in renal failure or that are severely dehydrated.

Adverse Effects

In ruminants, the adverse effect profile is related to excessive iodine (see Overdosage below). Young animals may be more susceptible to iodism than adults.

Foals have developed goiter when mares have been excessively supplemented.

Chronic use or overdoses may cause iodism. Cats are apparently more prone to developing this than other species. Signs can include vomiting, inappetence, depression, twitching, hypothermia, and cardiovascular failure.

Reproductive/Nursing Safety

Anecdotal reports that iodides can cause abortion in cattle persist and label information of some veterinary products state not to use in pregnant animals. Clearly, potential risks versus benefits of therapy must be weighed. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Iodides are excreted in milk. If iodides are required in the nursing dam, switch to milk replacer.

Overdosage/Acute Toxicity

Excessive iodine in animals can cause excessive tearing, vomiting, anorexia, nasal discharge, muscle twitching, cardiomyopathy, scaly haircoats/dandruff, hyperthermia, decreased milk production and weight gain, coughing, inappetence, and diarrhea.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving iodide and may be of significance in veterinary patients:

- **ANTITHYROID MEDICATIONS:** Iodides may decrease the efficacy of antithyroid medications
- **THYROID SUPPLEMENTS:** Iodides may enhance the efficacy of thyroid medications

Doses

■ DOGS:

For Sporotrichosis:

- a) Using SSKI: 40 mg/kg PO q8h for at least 60 days (Greene and Watson 1998)
- b) Using SSKI: 40 mg/kg PO q12h with food; itraconazole less likely to have adverse effects (Grooters 2005)

■ CATS:

For Sporotrichosis:

- 20 mg/kg PO q12–24h for at least 60 days (Greene and Watson 1998)
- Using SSKI: 20 mg/kg PO q12–24h with food; itraconazole less likely to cause adverse effects (Grooters 2005)

■ CATTLE, SHEEP & GOATS:

- For treatment of actinobacillosis (woody tongue): 70 mg/kg IV given as a 10% or 20% solution; repeat at least one more time at a 7–10 day interval. Refractory cases may require more frequent (2–3 day intervals) treatment. Severe, generalized, or refractory cases may require adjunctive treatment with antibiotics (sulfas, aminoglycoside or tetracyclines). (Smith 1996)
- For treatment of actinomycosis (lumpy jaw): 70 mg/kg IV given as a 10% or 20% solution at 7–10 day intervals or more frequently until signs of iodism occur (see Overdose above). Also requires adjunctive treatment with antibiotics: isoniazid (10 mg/kg/day PO for one month), penicillin (10,000 U/kg twice daily) and an aminoglycoside when treating a valuable animal or twice daily dosing for 7–14 days is possible. (Smith 1996)
- For treatment of actinobacillosis or actinomycosis in sheep: 20 mL of a 10% solution SC; repeated weekly for 4–5 weeks (Howard 1986)

■ HORSES:

- For treatment of sporotrichosis: Sodium iodide 20–40 mg/kg orally daily for several weeks (Fadok 1992)
- Loading dose of sodium iodide at 20–40 mg/kg IV for 2–5 days, then 20–40 mg/kg PO once daily for at least 3 weeks after all clinical lesions disappear. May administer via oral syringe or mixed in sweet feed. Topical hot packs of 20% sodium iodide may be used on open wounds. (Rees 2004)
- For Conidiobolomycosis: A mare with *C. coronatus* granulomatous tracheitis was successfully treated with 20% sodium iodide at 44 mg/kg IV for 7 days, then ethylenediamine dihydroiodide (iodide powder, granules) at 1.3 mg/kg PO q12h for 4 months, then q24h for 1 year, then once per week. Excessive lacrimation was occasionally noted, but resolved if the drug was held for one day. (Stewart and Salazar 2005)

Monitoring

- Clinical efficacy
- Signs of iodism (excessive tearing, nasal discharge, scaly hair-coats/dandruff, hyperthermia, decreased milk production and weight gain, coughing, inappetence, and diarrhea)

Client Information

- Although formal withholding times were not located, there is concern about using this product in food animals about to be slaughtered. In the interest of public health, contact FARAD (see appendix) for guidance.
- When giving orally in small animals, give with food or a fatty liquid (whole milk, cream) as the taste is extremely unpleasant and nausea or vomiting may otherwise occur.

Chemistry/Synonyms

Sodium iodide occurs as colorless, odorless crystals or white crystalline powder. It develops a brown tint upon degradation. Approximately 1 gram is soluble in 0.6 mL of water and 2 mL of alcohol.

Potassium iodide occurs as a clear to white granular powder. Approximately 1 gram is soluble in 0.7 mL of water. One gram (one mL) of SSKI contains 6 mEq of potassium.

Potassium iodide oral solution may also be known as SSKI (super saturated potassium iodide), or *Pima*®.

Storage/Stability/Compatibility

Commercially available veterinary injectable products should generally be stored at room temperature (15–30° C). Sodium iodide injection is reportedly physically **incompatible** with vitamins B and C injection.

Supersaturated potassium iodide (SSKI) solution should be stored below 40°C (104°F) and preferably between 15–30°C (59–86°F) in a tight, light-resistant container; protect from freezing. Crystallization can occur, particularly if stored at low temperatures; re-warming the contents and shaking will usually redissolve the crystals. If oxidation occurs, the solution will turn brownish yellow in color; discard should this occur.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Sodium Iodide Injection: 20 g/100 mL (20%; 200 mg/mL) in 250 mL vials—available as multi- or single use vials; generic, (AgriLabs, RXV, Vedco, Butler); (Rx) Approved for use in non-lactating cattle.

Oral iodide powders/granules for addition to feeds are available. Active ingredient is ethylenediamine dihydroiodide.

HUMAN-LABELED PRODUCTS:

Potassium Iodide Solution: 1 g potassium iodide/mL; 325 mg potassium iodide/5 mL in 30 mL, 24 mL, pt & gal; SSKI® (Upsher-Smith); generic; (Rx)

Potassium Iodide Oral Syrup: 62.5 mg potassium iodide/mL in pints and gallons; *Pima*® (Fleming); (Rx)

There are radioactive iodine compounds available for thyroid diagnostic and treatment.

IPECAC SYRUP

(*ip-e-kak*)

Also see the Decontamination information in the appendix

EMETIC

Prescriber Highlights

- Oral emetic agent for dogs & cats
- Contraindications: Rodents or rabbits; patients that are hypoxic, dyspneic, in shock, lack normal pharyngeal reflexes, seizing, comatose, severely CNS depressed or where CNS function is deteriorating, previously vomited repeatedly, ingested strong acids, alkalies, other caustic agents, or extremely physically weak
- Usually contraindicated after petroleum distillate ingestion
- Caution after ingestion of strychnine or other CNS stimulants (may precipitate seizures), preexisting severe cardiac dysfunction, esophageal or gastric abnormalities
- Adverse Effects: Rare at usual doses, but can induce lacrimation, salivation, & an increase in bronchial secretions; may cause repeated vomiting
- Food interactions

Uses/Indications

Ipecac can be used to induce vomiting in dogs and cats after ingestions of certain toxic compounds or drugs in overdose quantities.

Pharmacology/Actions

The major alkaloids of ipecac, emetine and cephaeline, are believed to cause the major pharmacologic actions of the drug. Ipecac acts both locally by irritating the gastric mucosa and centrally by stimulating the chemoreceptor trigger zone. The medullary centers must be responsive for emesis to occur, however. Contents of both the stomach and upper intestinal tract may be evacuated by ipecac.

Pharmacokinetics

Little is known regarding the pharmacokinetics of ipecac or its alkaloids. The amount absorbed tends to be highly interpatient variable. When administered to dogs or cats, vomiting usually occurs within 10–30 minutes (average = 23 minutes).

Contraindications/Precautions/Warnings

Emetics can be an important aspect in the treatment of orally ingested toxins, but must not be used injudiciously. Emetics should not be used in rodents or rabbits, because they are either unable to vomit or do not have stomach walls strong enough to tolerate the act of emesis. Emetics are also contraindicated in patients that are: hypoxic, dyspneic, in shock, lack normal pharyngeal reflexes, seizing, comatose, severely CNS depressed or when CNS function is deteriorating, or extremely physically weak. Emetics should be withheld in patients who have previously vomited repeatedly. Emetics are contraindicated in patients who have ingested strong acids, alkalis, or other caustic agents because of the risks of additional esophageal or gastric injury with emesis. Because of the risks of aspiration, emetics are usually contraindicated after petroleum distillate ingestion, but may be employed when the risks of toxicity of the compound are greater than the risks of aspiration. Use of emetics after ingestion of strychnine or other CNS stimulants may precipitate seizures.

Emetics generally do not remove more than 80% of the material in the stomach (usually 40–60%) and successful induction of emesis does not signal the end of appropriate monitoring or therapy. Because of the drug's potential cardiotoxic effects, use with caution in animals with preexisting severe cardiac dysfunction.

Because of its unpleasant taste, owners may have a difficult time administering to cats.

Warning: Do not confuse ipecac syrup with ipecac fluidextract, which is about 14 times more potent than ipecac syrup and could cause cardiotoxicity and death if used at ipecac syrup dosages. Ipecac fluidextract is no longer commercially available in the United States.

Adverse Effects

At recommended doses, ipecac rarely exhibits toxic effects, but can induce lacrimation, salivation, and an increase in bronchial secretions. In humans, ipecac has rarely caused protracted vomiting, diarrhea and lethargy.

If, after a second ipecac dose, emesis does not occur, many clinicians recommend performing gastric lavage to remove the ingested toxicant because of the potential for ipecac-induced cardiotoxicity or prolonged vomiting.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether ipecac alkaloids are excreted in milk; exercise caution.

Overdosage/Acute Toxicity

Overdoses of ipecac may result in serious cardiotoxicity with resulting arrhythmias, hypotension, or fatal myocarditis. No specific antidotal therapy is available, but activated charcoal may be given to help adsorb any unabsorbed ipecac; supportive therapy may also be employed.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ipecac and may be of significance in veterinary patients:

- **CHARCOAL, ACTIVATED:** While activated charcoal will adsorb ipecac syrup and several veterinary references state that ipecac should not be used when charcoal therapy is contemplated, ipecac may be given initially followed by activated charcoal after vomiting has occurred
- **MILK, DAIRY PRODUCTS, CARBONATED BEVERAGES:** Do not administer with milk, dairy products, or carbonated beverages as ipecac efficacy may be diminished

Doses

■ DOGS:

To induce emesis:

- a) 1–2.5 mL/kg PO; if animal has a nearly empty stomach, give 5 mL/kg of water immediately after ipecac (Beasley and Dorman 1990)
- b) 2–6 mL PO (Rumbeiha 2000)
- c) 1–2 mL/kg PO; do not exceed 15 mL total per dog; repeat in 20 minutes if emesis does not occur. If emesis does not occur after second dose, perform gastric lavage to recover ipecac. (Bailey 1989)

■ CATS:

To induce emesis:

- a) 3.3 mL/kg PO; because cats find ipecac syrup objectionable, a diluted 50:50 solution in water (total volume 6.6 mL/kg) via stomach or nasogastric tube may be preferable (Beasley and Dorman 1990)
- b) 1–2 teaspoonsful (5–10 mL) PO; may require second dose, but if not effective, institute gastric lavage (Reid and Oehme 1989)
- c) 1–2 mL/kg PO; repeat in 20 minutes if emesis does not occur. If emesis does not occur after second dose, perform gastric lavage to recover ipecac. (Bailey 1989)

Monitoring

- Cardiac function (rate/rhythm, blood pressure) should be monitored in susceptible animals and if animal does not vomit after ipecac
- Vomitus should be quantitated, examined for contents, and saved for possible later analysis

Client Information

- If clients are instructed to use this agent at home or in transit to professional help, they should save any vomitus for analysis

Chemistry/Synonym

Ipecac syrup is prepared from powdered ipecac, which is derived from the roots and rhizomes of certain plants. Ipecac has two active alkaloids, emetine and cephaeline. Each mL of Ipecac syrup contains 70 mg of powdered ipecac (1.23–1.57 mg of the ether soluble alkaloids). Ipecac syrup has a characteristic odor and occurs as a clear, to amber colored hydroalcoholic syrup.

Ipecac syrup may also be known as syrup of ipecac, ipecacuanha, ipecac, ipecacuanha syrup, ipecacuanha root, ipecacuanhae radix, *Ipecac*®, *Ipecacuanha Tincture*®, *Ipecavom*®, *Ipetitrin*®, or *Orpec*®.

Storage/Stability

Store ipecac syrup in tight containers at temperatures less than 25°C. Although ipecac syrup may be effective for several years after the labeled expiration date, delayed emetic action or lack of efficacy has been reported with the use of expired product; expired products cannot be recommended for use if alternatives exist.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ipecac Oral Syrup: 1.5% to 1.75% alcohol in 15 mL & 30 mL; (OTC); 2% alcohol in 15 and 30 mL; generic (Rx)

IPODATE SODIUM

(eye-poe-date)

ANTITHYROID AGENT

Prescriber Highlights

- ▶ Organic iodine compound that may be useful in some cats for medical treatment of hyperthyroidism
- ▶ Very limited experience
- ▶ Less effective for cats with severe hyperthyroidism
- ▶ Efficacy may be transient
- ▶ Dosage forms must be compounded

Uses/Indications

Iodate may be useful in some cats for the medical treatment of hyperthyroidism when methimazole (or carbimazole) cannot be tolerated. Because it uses a different mechanism of action than methimazole, iodate may, potentially, be useful in reducing methimazole dosages (and hence toxicity).

Pharmacology/Actions

Iodate's efficacy in treating hyperthyroidism is thought to be primarily due to inhibition of the conversion of T₄ to T₃. Iodate may also block T₃ receptors and thereby protecting the heart from the hypertrophic effects of hyperthyroidism. It may block the actions of TSH.

Pharmacokinetics

The drug is well absorbed after oral administration. Other pertinent pharmacokinetic data for cats is unavailable.

Contraindications/Precautions/Warnings

Iodate is contraindicated in patients with known hypersensitivity to it. It should be used with caution in patients who have had previous reactions to iodine compounds. Humans with hepatic dysfunction should not receive multiple doses of the drug as renal toxicity has resulted in a few patients. It is recommended for use with caution in human patients with hyperuricemia (possible uric acid nephropathy).

Adverse Effects

Cats reportedly tolerate iodate well, but may become refractory to treatment after a relatively short time. Oral iodine containing

products can cause GI distress (nausea, vomiting, diarrhea, cramping, inappetence). Skin rashes, itching, dizziness and headache have been reported by human patients.

Reproductive/Nursing Safety

If administered to pregnant cats, congenital hypothyroidism is a possibility.

Overdosage/Acute Toxicity

No specific information located. Cats have reportedly tolerated daily doses up to 400 mg.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving iodate and may be of significance in veterinary patients:

- **IODINE, RADIOACTIVE:** Iodate may interfere with radioactive iodine therapy. It is suggested to treat no sooner than 2 weeks after discontinuing iodate (3–4 weeks or more if possible).

Laboratory Considerations

- Iodate may increase **BSP** retention times and **serum bilirubin** levels
- False positive **urine protein** determinations may occur

Doses

■ CATS:

For medical treatment of hyperthyroidism in patients who cannot tolerate methimazole and whose owners will not permit surgery or radioiodine therapy:

- a) 100–200 mg (total dose) PO once daily (Lorenz and Melendez 2002a)
- b) 50 mg per cat PO twice daily, if “good” clinical response not obtained, at 2 week intervals may increase dose to 150 mg/day (100 mg AM, 50 mg PM) and then to 200 mg/day (100 mg twice daily). Cats with severe hyperthyroidism are less likely to respond. (Murray and Peterson 1997)
- c) For use before surgery: 15 mg/kg PO q12h. (Jones 2006)

Monitoring

- Clinical efficacy (heart rate, body weight, etc.)
- Serum T₃ (**Note:** T₄ did not change—remained high in study group)

Client Information

- It must be stressed to owners that this drug will decrease excessive thyroid hormones, but does not cure the condition and that compliance with the treatment regimen is necessary for success.
- Long-term efficacy is questionable.

Chemistry/Synonyms

An orally administered radiopaque organic iodine compound, iodate sodium occurs as a white to off-white, fine crystalline powder. It is freely soluble in alcohol and water. Each 500 mg capsule contains 61.4% (or 333.4 mg) of iodine.

Iodate calcium may also be known as: calcium iodate, calcium iodate, iodate calcium, *Solu-Biloptin*®, and *Solubiloptine*®.

Iodate sodium may also be known as: sodium iodate, sodium iodate, NSC-106962, *Bilivist*®, *Biloptin*®, and *Oragrafin*®.

Storage/Stability

Store capsules in tight containers and protect from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

None; must obtained via a compounding pharmacy.

Note: Most of the studies using ipodate in cats have been done with calcium ipodate. It is likely that sodium ipodate would be fairly equivalent. If the compounding pharmacy has access to calcium ipodate, it is suggested to use that form.

IPRATROPIUM BROMIDE

(eye-prah-troh-pee-um) Atrovent®

INHALED ANTIMUSCARINIC

Prescriber Highlights

- ▶ Inhaled antimuscarinic agent for adjunctive treatment of bronchoconstrictive conditions
- ▶ Very little information available for use in small animals
- ▶ Likely safe
- ▶ May need to be administered quite often, duration of activity is relatively short

Uses/Indications

Locally administered (inhaled) ipratropium bromide can be used for the adjunctive treatment of bronchospastic conditions.

Pharmacology/Actions

Ipratropium inhibits vagally mediated reflexes by antagonizing acetylcholine. Increases in intracellular concentrations of cyclic guanosine monophosphate (cyclic GMP) secondary to acetylcholine are prevented, thereby reducing bronchial smooth muscle constriction.

Pharmacokinetics

Because the medication is inhaled, minimal drug is absorbed in the systemic circulation. In humans, elimination half-life is about 2 hours. In healthy cats with experimentally induced bronchospasm, inhaled (neb) ipratropium gave maximal efficacy for about 4 hours. When combined with albuterol (salbutamol), increased efficacy resulted. (Leemans, Kischvink et al. 2006) In horses, duration of effect is approximately 4–6 hours.

Contraindications/Precautions/Warnings

Ipratropium is contraindicated in patients hypersensitive to it or other atropine derivatives.

It should be used with caution in other conditions where antimuscarinics may be harmful, including narrow-angle glaucoma, bladder-neck obstruction, or prostatic hypertrophy.

Adverse Effects

Adverse effects are unlikely to be significant. Tracheal or bronchial irritation (coughing) have been reported on occasion. Allergic responses are possible and some patients develop anticholinergic effects.

Reproductive/Nursing Safety

Large oral dosages in laboratory animals did not cause teratogenic effects. In humans, the FDA categorizes ipratropium as category **B** for use during the first two trimesters of pregnancy (*Animal studies*

have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.)

Ipratropium is likely to be safe to use during nursing.

Overdosage/Acute Toxicity

Overdosage is unlikely to be a cause for concern. The drug is not well absorbed orally or after inhalation and oral LD50 values for laboratory animals were greater than 1 gram/kg.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ipratropium and may be of significance in veterinary patients:

- **ANTICHOLINERGIC DRUGS:** May cause additive antimuscarinic effects
- **BETA-ADRENERGIC AGONISTS** (e.g., **albuterol**): May have additive therapeutic effects

Laboratory Considerations

No specific concerns were noted

Doses

■ HORSES:

For RAO, heaves:

- a) 90–180 mcg inhaled aerosol q12h (Rush 2006a)

Monitoring

- Clinical efficacy

Client Information

- If using the aerosol metered dose inhalers, do not use after 200 inhalations (puffs) even if there appears to be medication remaining; active ingredient cannot be assured; do not shake the HFA canister before using
- This medication is not for treating an acute asthma attack, it is for maintenance treatment

Chemistry/Synonyms

Ipratropium bromide occurs as a white or almost white crystalline powder. It is soluble in water and slightly soluble in alcohol. The pH of a 1% solution is between 5 and 7.5.

Ipratropium bromide may also be known as Sch-1000; many trade names are available including *Atrovent*.®

Storage/Stability/Compatibility

The solution for inhalation should be stored at room temperature and protected from light. Keep in foil pouch until time of use. The metered dose inhalers should be stored at room temperature.

The solution for nebulization may be mixed with albuterol or metaproterenol if used within one hour.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ipratropium Bromide Solution for Inhalation: 0.02% (500 mcg) in 2.5 mL UD “nebs”; generic (Dey); (Rx)

Ipratropium Bromide Aerosol for Inhalation: each actuation delivers 17 mcg in 12.9 g metered dose inhaler; *Atrovent*® HFA (BI); (Rx)

Ipratropium Bromide Aerosol for Inhalation: each actuation delivers 18 mcg in 14.7 g metered dose inhaler; *Atrovent*® (BI); (Rx)

Nasal sprays are available, and in combination with albuterol as nebs: *DuoNeb*® (Dey) and as a metered dose inhaler, *Combivent*® (BI).

IRBESARTAN

(ihr-beh-sar-tan) Avapro®

ANGIOTENSIN-II RECEPTOR BLOCKER (ARB)

Prescriber Highlights

- ▶ ARB that may be useful in treating dogs with hypertension secondary to renal insufficiency
- ▶ Very limited experience in veterinary medicine
- ▶ Not safe during pregnancy

Uses/Indications

Although experience in veterinary medicine is minimal irbesartan may be useful in treating canine hypertension associated with renal insufficiency. It may be effective in treating heart failure when dogs are unable to tolerate ACE inhibitors, but documentation for this use is lacking. One study, using very high irbesartan dosages (60 mg/kg PO twice daily) in dogs with subacute mitral regurgitation, demonstrated no improvement in left ventricular function or prevention of left ventricular remodeling (Perry, Wei et al. 2002).

Pharmacology/Actions

Irbesartan is an angiotensin-II receptor blocker (ARB). By selectively blocking the AT₁ receptor, aldosterone synthesis and secretion is reduced causing vasodilation and decreased potassium and increased sodium excretion. While plasma concentrations of renin and angiotensin-II are increased, this does not counteract the blood pressure lowering effects of irbesartan. Irbesartan does not interfere with substance P or bradykinin responses.

Irbesartan does not need to be converted to an active metabolite as does the ARB, losartan (*Cozaar*®). Dogs, unlike humans, reportedly do not convert losartan to the active metabolite.

Pharmacokinetics

After single 30 mg/kg oral doses in dogs with experimentally induced renal hypertension, irbesartan peak levels occurred between 3–4 hours later and elimination half-life was approximately 9 hours. After 30 mg/kg doses PO once daily for 8 days, the elimination half-life was approximately 21 hours (Huang, Qiu et al. 2005).

In humans, absorption is rapid and bioavailability ranges from 60–80%. Peak levels occur in about 1.5–2 hours. Bioavailability is not altered by the presence of food. The drug is 90% bound to plasma proteins and crosses the blood-brain barrier and placenta in small quantities. Irbesartan is metabolized in the liver via glucuronidation and oxidation; metabolites are not active. Both metabolites and unchanged drug are eliminated primarily in the feces and to a lesser extent, in urine. Terminal elimination half-life ranges from 11–15 hours. Dosages do not need to be adjusted in patients with renal dysfunction.

Contraindications/Precautions/Warnings

Patients who are volume or sodium depleted should have these corrected before starting therapy. Do not use in hypotensive patients. In humans, the drug is contraindicated in patients hypersensitive to it. It should not be used during pregnancy (see Reproductive Safety).

Adverse Effects

An adverse effect profile for dogs is not known due to limited use of this medication. In humans, the most commonly reported adverse effects include diarrhea, dyspepsia, fatigue, and orthostatic dizziness/hypotension.

Reproductive/Nursing Safety

Irbesartan is not safe to use during pregnancy. Studies in pregnant rats given high doses demonstrated a variety of fetal abnormalities (renal pelvic cavitation, hydroureter, absence of renal papilla). Smaller doses in rabbits caused increased maternal death and spontaneous abortion. In humans, the drug is considered teratogenic, particularly during the 2nd and 3rd trimesters. During this time, the FDA categorizes irbesartan as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) If pregnancy is detected in patients receiving irbesartan, the drug should be discontinued as soon as possible.

Because small amounts of irbesartan have been detected in rat milk, and there is significant concern about the safety of the drug in neonates, the manufacturer recommends that it not be used in nursing women.

Overdosage/Acute Toxicity

Rats and mice survived acute oral overdoses in excess of 2000mg/kg. Likely effects seen in an overdose situation include hypotension and either bradycardia or tachycardia; treatment is supportive. Contact an animal poison control center for further information.

Drug Interactions

In humans or veterinary patients, no clinically significant drug interactions have been reported. Because of the drug's pharmacologic actions, use caution with other drugs that can reduce blood pressure.

Laboratory Considerations

No specific concerns were noted

Doses

■ DOGS:

- a) As an alternative to ACE inhibitors for treatment of hypertension associated with renal insufficiency: 5 mg/kg PO q12–24 hours. (Brown 2004)

Monitoring

- Blood pressure, heart rate
- Serum electrolytes, BUN, creatinine
- Adverse Effects: possibly GI (diarrhea), somnolence/activity changes

Client Information

- Clients should understand that veterinary experience with this medication is limited and that the adverse effect profile is not well known; anything unusual should be reported to the veterinarian
- May be given with food or on an empty stomach

Chemistry/Synonyms

Irbesartan is a nonpeptide angiotensin-II antagonist and occurs as white to off-white, crystalline powder. It is practically insoluble in water and slightly soluble in alcohol.

Irbesartan may also be known as: BMS 186295, SR 47436, Irbesartanum, *Aprovel*®, *Arbit*®, *Avalide*®, *Avapro*®, *Cavapro*®, *Coaproval*®, *Ecard*®, *Ibsan*®, *Irbat*®, *Irbes*®, *Iretensa*®, *Irovel*®, *Irvell*®, *Isart*®, and *Karvea*®.

Storage/Stability

Irbesartan tablets should be stored at room temperature (15–30°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance.

HUMAN-LABELED PRODUCTS:

Irbesartan Tablets: 75 mg, 150 mg, & 300 mg; *Avapro*® (Bristol-Myers Squibb); (Rx)

Irbesartan 150 mg with Hydrochlorothiazide 12.5 mg Tablets, Irbesartan 300 mg with Hydrochlorothiazide 12.5 mg or 25 mg Tablets; *Avalide*®; (Bristol-Myers Squibb); (Rx)

IRON DEXTRAN

(eye-urn dex-tran)

INJECTABLE HEMATINIC**Prescriber Highlights**

- ▶ **Injectable hematinic**
- ▶ **Contraindications:** Known hypersensitivity to iron dextran, or with any anemia other than iron deficiency anemia; acute renal infections, in conjunction with oral iron supplements
- ▶ **Adverse Effects:** Prostration & muscular weakness, anaphylactoid reactions
- ▶ **High dosages may cause increased incidences of teratogenicity & embryotoxicity**
- ▶ **Pigs born of vitamin E/selenium-deficient sows may demonstrate nausea, vomiting, & sudden death within 1 hour of injection**
- ▶ **IM use in pigs after 4 weeks of age may cause muscle tissue staining**

Uses/Indications

Iron dextran is used in the treatment and prophylaxis of iron deficiency anemias, primarily in neonatal food-producing animals.

Pharmacology/Actions

Iron is necessary for myoglobin and hemoglobin in the transport and utilization of oxygen. While neither stimulating erythropoiesis nor correcting hemoglobin abnormalities not caused by iron deficiency, iron administration does correct both physical signs and decreased hemoglobin levels secondary to iron deficiency.

Ionized iron is a component in the enzymes cytochrome oxidase, succinic dehydrogenase, and xanthine oxidase.

Pharmacokinetics

After IM injection, iron dextran is slowly absorbed primarily via the lymphatic system. About 60% of the drug is absorbed within 3 days of injection and up to 90% of the dose is absorbed after 1–3 weeks. The remaining drug may be absorbed slowly over several months.

After absorption, the reticuloendothelial cells of the liver, spleen, and bone marrow gradually clear the drug from plasma. The iron is cleaved from the dextran component and the dextran is then metabolized or excreted. The iron is immediately bound to protein elements to form hemosiderin, ferritin or transferrin. Iron crosses

the placenta, but in what form is unknown. Only traces of iron are excreted in milk.

Iron is not readily eliminated from the body. Iron liberated by the destruction of hemoglobin is reused by the body and only small amounts are lost by the body via hair and nail growth, normal skin desquamation, and GI tract sloughing. Accumulation can result with repeated dosing as only trace amounts of iron are eliminated in the feces, bile, or urine.

Contraindications/Precautions/Warnings

Iron dextran is contraindicated in patients with known hypersensitivity to it or with any anemia other than iron deficiency anemia. It is not to be used in patients with acute renal infections, and should not be used in conjunction with oral iron supplements.

Adverse Effects

The manufacturers of iron dextran injection for use in pigs state that occasionally pigs may react after injection with iron dextran, characterized by prostration and muscular weakness. Rarely, death may result from an anaphylactoid reaction. Iron dextran used in pigs born of vitamin E/selenium-deficient sows may demonstrate nausea, vomiting, and sudden death within 1 hour of injection. Iron dextran injected IM in pigs after 4 weeks of age may cause muscle tissue staining.

Large SC doses have been associated with the development of sarcomas in laboratory animals (rabbits, mice, rats, and hamsters).

Reproductive/Nursing Safety

High dosages may cause increased incidences of teratogenicity and embryotoxicity. Use only when clearly necessary at recommended doses in pregnant animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Traces of unmetabolized iron dextran are excreted in milk.

Overdosage/Acute Toxicity

Depending on the size of the dose, inadvertent overdose injections may require chelation therapy. For more information, refer to the Ferrous Sulfate monograph for information on using deferoxamine and other treatments for iron toxicity.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving iron and may be of significance in veterinary patients:

- **CHLORAMPHENICOL:** Because chloramphenicol may delay the response to iron administration, avoid using chloramphenicol in patients with iron deficiency anemia

Laboratory Considerations

- Large doses of injectable iron may discolor the serum brown which can cause falsely elevated **serum bilirubin** values and falsely decreased **serum calcium** values.
- After large doses of iron dextran, **serum iron** values may not be meaningful for up to 3 weeks.

Doses■ **DOGS:**

For iron deficiency anemia:

- a) Iron dextran 10–20 mg/kg once, followed by oral therapy with ferrous sulfate (see ferrous sulfate monograph) (Weiser 1989b)

■ **CATS:**

For iron deficiency anemia:

- For prevention of transient neonatal iron deficiency anemia: 50 mg iron dextran injection at 18 days of age (Weiser 1989a)
- For adjunctive therapy with erythropoietin treatment: 50 mg IM q3–4 weeks (Cowgill 2002)
- For adjunctive therapy with erythropoietin treatment in cats who cannot tolerate oral iron therapy: 50 mg IM q3–4 weeks (Hoskins 2005b)

■ **FERRETS:**

- 10 mg/kg IM once weekly (Williams 2000)

■ **SWINE:**

For prevention of iron deficiency anemia in baby pigs (1–3 days of age):

- 100–150 mg of elemental iron IM per pig. (Label directions; *Ferrextran-100*®—Fort Dodge)

For treatment of iron deficiency anemia in baby pigs:

- 100–200 mg of elemental iron IM per pig. May repeat in 10–14 days. Label directions; *Ferrextran-100*®—Fort Dodge)

■ **BIRDS:**

For iron deficiency anemia or following hemorrhage:

- 10 mg/kg IM; repeat in 7–10 days if PCV fails to return to normal (Clubb 1986)
- 10 mg/kg IM; repeat weekly (McDonald 1989)

Monitoring

- If indicated: CBC, RBC indices
- Adverse reactions

Client Information

- In pigs, inject IM in the back of the ham

Chemistry/Synonyms

Iron dextran is a complex of ferric oxyhydroxide and low molecular weight partially hydrolyzed dextran derivative. The commercially available injection occurs as a dark brown, slightly viscous liquid that is completely miscible with water or normal saline and has a pH of 5.2–6.5.

Iron dextran may also be known as: iron–dextran complex, *Cosmofer*®, *DexFerrum*®, *Dexiron*®, *Driken*®, *Fercayl*®, *Ferrocel*®, *Ferroin*®, *Ferrum Hausmann*®, *Fexiron*®, *Imferdex*®, *Imferon*®, *InFeD*®, and *Infufer*®.

Storage/Stability/Compatibility

Iron dextran injection should be stored at room temperature (15–30°C); avoid freezing. Iron dextran injection is reportedly physically **incompatible** when mixed with oxytetracycline HCl and sulfadiazine sodium.

Dosage Forms/Regulatory Status/Withdrawal Times**VETERINARY-LABELED PRODUCTS:**

Iron Dextran Injection: 100 mg of elemental iron/mL and 200 mg of elemental iron/mL in 100 mL vials; various manufacturers and trade names; (OTC). Approved for use in swine. No slaughter withdrawal time required.

HUMAN-LABELED PRODUCTS:

Iron Dextran Injection: 50 mg of elemental iron/mL (as dextran) in 1 mL & 2 mL single-dose vials; *InFeD*® (Schein); *DexFerrum*® (American Regent); (Rx)

ISOFLUPREDONE ACETATE

(eye-so-floo-preh-dohn) Predef 2X®

INJECTABLE GLUCOCORTICOID

For topical or otic use of isoflupredone, see the Topical Dermatological Agents, and Otic Appendixes

Prescriber Highlights

- **Injectable glucocorticoid labeled for use in cattle, horses & swine for antiinflammatory & immunosuppressive effects**
- **Less likely to cause early parturition than dexamethasone or betamethasone, but avoid use in pregnancy**
- **May have mineralocorticoid effects in horses & cattle; hypokalemia has been noted**

Uses/Indications

Isoflupredone acetate is a potent glucocorticoid and like other glucocorticoids can be used for its antiinflammatory or immunosuppressive effects. Labeled indications for isoflupredone include: adjunctive treatment of bovine ketosis, alleviating pain and lameness associated with musculoskeletal conditions, acute hypersensitivity reactions, adjunctive treatment of overwhelming infections with severe toxicity, shock, supportive therapy in the treatment of stress conditions (e.g., surgery), dystocia, retained placenta, inflammatory ocular conditions, snakebite and parturient paresis.

In horses, isoflupredone has been used parenterally to reduce inflammation associated with recurrent airway obstruction (RAO, “heaves”, COPD).

While the drug could be used in small animals, it is recommended to use other glucocorticoid agents instead, where there has been more experience and other approved products for dogs and cats are available.

Pharmacology/Actions

Isoflupredone’s antiinflammatory potency is approximately 17 times that of hydrocortisone (cortisol). The label states that the glucocorticoid activity of isoflupredone is 50 times that of hydrocortisone and 10 times that of prednisolone as measured by liver glycogen deposition in rats. Isoflupredone reportedly has minimal mineralocorticoid effects, but recent work has demonstrated that it can cause hypokalemia.

For more information on the pharmacologic actions associated with glucocorticoids, see the *Glucocorticoid Agents, General Information* monograph.

Pharmacokinetics

No specific pharmacokinetic values were located. The manufacturer states that gluconeogenic activity persists for 48 hours after dosing in cattle.

Contraindications/Precautions/Warnings

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison’s), when administered IM in patients with idiopathic thrombocytopenia, and in patients hypersensitive to a particular compound. Because of their ulcerogenic potential, glucocorticoids should be used with extreme caution in patients with active GI ulcers or those susceptible to them. Use cautiously in patients with diabetes mellitus.

Chronic use in young, growing animals must be undertaken cautiously, as decreased growth may occur.

Not to be used in calves to be processed into veal.

See Reproductive Safety for information on use during pregnancy.

Adverse Effects

Adverse effects are generally associated with long-term administration of glucocorticoids, particularly if given at higher dosages; these effects generally are manifested as signs of hyperadrenocorticism. Recent research has indicated, however, that even single doses administered to dairy cattle can cause hypokalemia. Potential adverse effects include: reduced milk production, hypokalemia, delayed wound healing, GI ulceration, increased infection rates, diabetes mellitus exacerbation/hyperglycemia, pancreatitis, hepatopathy, renal dysfunction, osteoporosis, laminitis (horses), hypothyroidism, and hyperlipidemia.

When administered to young, growing animals, glucocorticoids can retard growth.

Reproductive/Nursing Safety

Avoid using isoflupredone during pregnancy. Glucocorticoids can induce abortion or early parturition in the later stages of pregnancy; most commonly seen in ruminants. Isoflupredone appears to have a lower abortifacient potential (like hydrocortisone, prednisolone, triamcinolone) than steroids such as dexamethasone, betamethasone or flumethasone; it may induce premature parturition with retained placenta and its use should be avoided during the later stages of pregnancy.

Glucocorticoids used during the first trimester have been linked to a variety of teratogenic effects in dogs and laboratory animals.

Glucocorticoid administration may reduce milk production. Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may potentially inhibit the growth of nursing newborns.

Overdosage/Acute Toxicity

A single overdose of isoflupredone is unlikely to cause harmful effects. Should clinical signs require intervention, use supportive treatment.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to the Adverse Effects section for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving isoflupredone or other glucocorticoids and may be of significance in veterinary patients:

- **DIGITALIS GLYCOSIDES (digoxin):** Increased chance of digitalis toxicity may occur should hypokalemia develop; diligent monitoring of potassium and digitalis glycoside levels is recommended
- **POTASSIUM-DEPLETING DIURETICS (furosemide, thiazides):** Administered concomitantly with glucocorticoids may cause hypokalemia
- **SALICYLATES:** Glucocorticoids may reduce salicylate blood levels
- **ULCEROGENIC DRUGS (e.g., NSAIDs):** With glucocorticoids may increase the risk of gastrointestinal ulceration
- **VACCINES, TOXOIDS, BACTERINS:** A diminished immune response may occur after vaccine, toxoid, or bacterin administration; patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented

Laboratory Considerations

- Glucocorticoids may increase **serum cholesterol** and **serum and urine glucose** levels
- Glucocorticoids may decrease **serum potassium**
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T₃ & T₄** values; thyroid gland atrophy has been reported after chronic glucocorticoid administration
- Reactions to **skin tests** may be suppressed by glucocorticoids.
- Glucocorticoids may cause false-negative results of the **nitroblue tetrazolium test** for systemic bacterial infections.

Doses

■ CATTLE:

- a) For labeled systemic indications: 10–20 mg (total dose) IM, according to the size of the animal and severity of the condition. The dose may be repeated in 12 to 24 hours if indicated. (Label information; *Predef 2X*®—Pharmacia & Upjohn)

■ HORSES: (Note: RCI: Class 4)

- a) For labeled systemic indications: 5–20 mg (total dose) IM repeated as necessary. For intrasynovial administration: 5–20 mg or more depending on the size of the joint cavity. (Label information; *Predef 2X*®—Pharmacia & Upjohn)
- b) For intraarticular administration: 4–20 mg; has a short to medium duration of action. (Goodrich 2006)
- c) For treatment of “heaves” (RAO): 10–14 mg (total dose) IM once daily for a horse weighing between 450–500 kg. (Lavoie 2003)
- d) For treatment of recurrent airway obstruction (RAO): 0.03 mg/kg IM once daily. Patients were treated for 14 days and developed significant decreases in serum potassium. (Picardet, Leguillette et al. 2003)

■ SWINE:

- a) For labeled systemic indications: 5 mg (total dose) IM for a 300 lb. animal. Adjust dose proportionally for a smaller or larger animal. (Label information; *Predef 2X*®—Pharmacia & Upjohn)

Monitoring

- Single injections may not require monitoring beyond observation of the patient for efficacy and adverse effects, but consider evaluating serum potassium
- Ongoing usage requires enhanced monitoring including: renal and liver function, CBC, blood glucose and serum electrolytes
- ACTH stimulation tests may be indicated to determine extent of HPA axis suppression
- Consider thyroid hormone monitoring if use is prolonged or patient exhibits signs associated with thyroid hormone deficiency

Client Information

- If used in dairy cattle, warn producer that milk production may be affected
- If owners are to administer the medication, caution them to only administer as the veterinarian directs

Chemistry/Synonyms

Isoflupredone acetate is a fluorinated synthetic corticosteroid with a molecular weight of 420.5. The commercial injection is in an aqueous suspension that also contains sodium citrate, polyethylene glycol 3350, and povidone.

Isoflupredone acetate may also be known as: U-6013, 9alpha-fluoroprednisolone acetate, and *Predef 2x*®.

Storage/Stability

The injection should be stored at controlled room temperature 20°–25°C.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Isoflupredone acetate 2 mg/mL aqueous suspension for injection in 10 mL and 100 mL vials; *Predef 2x*® (Pharmacia & Upjohn); (Rx). In the USA, *Predef 2x*® is approved for use in cattle, horses and swine. Meat withdrawal time is 7 days; it is not to be used in calves to be processed for veal. There is no milk withdrawal time for isoflupredone in the USA, but in Canada a 72-hour withdrawal time is specified.

Isoflupredone is also found in some topical and otic products. For more information see the *Dermatological Agents, Topical and Otic* Appendixes.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance.

HUMAN-LABELED PRODUCTS: None

ISOFLURANE

(eye-soe-*flure*-ane) Isoflo®, Iso-Thesia®

GENERAL ANESTHETIC, INHALANT

Prescriber Highlights

- ▶ Inhalant general anesthetic
- ▶ Contraindications: History or predilection towards malignant hyperthermia
- ▶ Caution with increased CSF or head injury, or myasthenia gravis
- ▶ Adverse Effects: Dose related hypotension, respiratory depression, & GI effects (nausea, vomiting, ileus); cardiodepression generally is minimal at doses causing surgical planes of anesthesia. Arrhythmias are rare.
- ▶ May be fetotoxic
- ▶ Drug interactions

Uses/Indications

Isoflurane is an inhalant anesthetic that has some distinct advantages over either halothane or methoxyflurane due to its lessened myocardial depressant and catecholamine sensitizing effects, and the ability to use it safely in patients with either hepatic or renal disease. Isoflurane's higher cost than either methoxyflurane or halothane is a disadvantage.

Horses may recover more rapidly than with halothane, but be more susceptible to anesthetic associated-myopathy.

Pharmacology/Actions

While the precise mechanism that inhalant anesthetics exert their general anesthetic effects is not precisely known, they may interfere with functioning of nerve cells in the brain by acting at the lipid matrix of the membrane. Some key pharmacologic effects noted with isoflurane include: CNS depression, depression of body temperature regulating centers, increased cerebral blood flow, respiratory depression, hypotension, vasodilatation, myocardial depression (less so than with halothane), and muscular relaxation.

Minimal Alveolar Concentration (MAC; %) in oxygen reported for isoflurane in various species: Dog = 1.5; Cat = 1.2; Horse = 1.31;

Human = 1.2. Several factors may alter MAC (acid/base status, temperature, other CNS depressants on board, age, ongoing acute disease, etc.).

Pharmacokinetics

Isoflurane is rapidly absorbed from the alveoli. It is rapidly distributed into the CNS and crosses the placenta. The vast majority of the drug is eliminated via the lungs; only about 0.17% is metabolized in liver and only very small amounts of inorganic fluoride is formed.

Contraindications/Precautions/Warnings

Isoflurane is contraindicated in patients with a history or predilection towards malignant hyperthermia. It should be used with caution (benefits vs. risks) in patients with increased CSF or head injury, or myasthenia gravis.

Adverse Effects

Hypotension (secondary to vasodilation, not cardiodepression) may occur and is considered to be dose related. Dose-dependent respiratory depression, and GI effects (nausea, vomiting, ileus) have been reported. While cardiodepression generally is minimal at doses causing surgical planes of anesthesia, it may occur. Arrhythmias have rarely been reported.

Reproductive/Nursing Safety

Some animal studies have indicated that isoflurane may be fetotoxic. Use during pregnancy with caution. In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving isoflurane and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** Use with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur
- **LINCOSAMIDES:** Use with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur
- **NON-DEPOLARIZING NEUROMUSCULAR BLOCKING AGENTS:** Additive neuromuscular blockade may occur
- **SUCCINYLCHOLINE:** With inhalation anesthetics, may induce increased incidences of cardiac effects (bradycardia, arrhythmias, sinus arrest and apnea) and, in susceptible patients, malignant hyperthermia
- **SYMPATHOMIMETICS (dopamine, epinephrine, norepinephrine, ephedrine, metaraminol, etc.):** While isoflurane sensitizes the myocardium to the effects of sympathomimetics less so than halothane, arrhythmias may still result. If these drugs are needed, they should be used with caution and in significantly reduced dosages with intensive monitoring

Doses**■ DOGS & CATS:**

(**Note:** Concentrations are dependent upon fresh gas flow rate; the lower the flow rate, the higher the concentration required.)

- a) 5% induction; 1.5–2.5% maintenance (Papich 1992)
- b) 0.5–3 %, inhaled (Hubbell 1994)

■ FERRETS/SMALL MAMMALS:

- a) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: Using a non-rebreathing system: Induction: 2–3%, maintenance: 0.25–2% (Anderson 1994); (Adamcak and Otten 2000)

- b) Ferrets: After premed with medetomidine at 50–100 mcg/kg. Atropine at 0.05 mg/kg SC is used to counteract hypersalivation and bradycardia. Starting isoflurane at 1–2% will be less irritating to the ferret and cause less of a struggle. Use a non-rebreathing system. Consider intubation in procedures lasting longer than 30 minutes. For post-op pain either butorphanol at 0.1 mg/kg SC or buprenorphine at 0.02 mg/kg SC. (Johnson 2006c)

■ REPTILES:

- a) Give 5% isoflurane and oxygen in a clear plastic bag or induction chamber. Fill chamber with gas and seal. Induction time may take 30–60 minutes, but can be shortened to 15–30 minutes with increased depth of anesthesia if animal is injected with 10–20 mg/kg of ketamine (SC or IM). Patient should be kept warm by placing on a water blanket. Surgical anesthesia can be determined by the loss of righting reflex. After induction, use either a mask, ET tube, or leave head in chamber. Maintenance levels are 3–5% (if isoflurane used alone). If apnea occurs during or after anesthesia, discontinue gas anesthetic and apply gentle manual ventilation 2–4 times per minute with small doses of doxapram IV. Normal respiration generally resumes in 3–5 minutes. Righting reflex generally recovers in an hour, but animal may be tranquilized for up to 24 hours. (Gillespie 1994)
- b) Anesthetic gas of choice for reptiles. Induction can be with a face mask, or with a “cat box.” Animal may be intubated, especially if has been preanesthetized with ketamine or *Te-lazol*, and “bag” it down with positive pressure ventilation. Maintenance is usually 1.5–3%. (Funk 2002)

■ BIRDS:

- a) Small birds can be anesthetized safely in 15–30 seconds at 4% (Ludders 1992)
- b) Induction occurs within 1–2 minutes at a concentration of 3–5%. Maintenance at 1.5–2% is adequate for most birds. Anesthetic of choice for birds; heart rate may decrease, but not to the same degree as halothane. Recovery very rapid; most patients are standing and cage safe within 5 min. after anesthesia discontinued, but there seems to be a direct relationship between anesthesia time and recovery time. (Bennett 2002)

Monitoring

- Respiratory and ventilatory status
- Cardiac rate/rhythm; blood pressure (particularly with “at risk” patients)
- Level of anesthesia

Chemistry/Synonyms

An inhalant general anesthetic agent, isoflurane occurs as a colorless, nonflammable, stable liquid. It has a characteristic mildly pungent musty, ethereal odor. At 20°C, isoflurane’s specific gravity is 1.496 and vapor pressure is 238 mm Hg.

Isoflurane may also be known as: compound 469, isofluranum, *AErrane*®, *Forene*®, *Forenium*®, *Forthane*®, *Isoflo*®, *Isofor*®, *Isoforine*®, *Isosol*®, *Isothane*®, *Iso-Thesia*®, *Lisorane*®, *Sofloran*®, *Tensocold*®, *Terrell*® and *Zuflax*®.

Storage/Stability/Compatibility

Isoflurane should be stored at room temperature; it is relatively unaffected by exposure to light, but should be stored in a tight, light-resistant container. Isoflurane does not attack aluminum, brass, tin, iron, or copper.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Isoflurane Inhalation Anesthetic: 99.9%/mL in 100 mL and 250 mL bottles; *Isoflo*® (Abbott), *Isosol*® (Vedco), *Iso-Thesia*® (Butler), generic, (Halocarbon, VetOne, Phoenix Pharmaceutical); (Rx). Approved for use in horses (those not intended for food) and dogs.

HUMAN-LABELED PRODUCTS:

Isoflurane in 100 mL bottles; *Forane*® (Anaquest); *Terrell*® (Minrad); generic (Abbott); (Rx)

ISONIAZID (INH)

(eye-so-nye-ah-zid) Isonicotinic acid hydrazide

ANTIMYCOBACTERIAL

Prescriber Highlights

- Antimycobacterial that may be used for chemoprophylaxis of *M. bovis* or *M. tuberculosis* in small animals
- Treating active infections is controversial because of potential public health risks associated with the infections
- Hepatotoxicity & neurotoxicity possible; narrow therapeutic index

Uses/Indications

Isoniazid (INH) is sometimes used for chemoprophylaxis in small animals in households having a human with tuberculosis. It potentially can be used in combination with other antimycobacterial drugs to treat infections of *M. bovis* or *M. tuberculosis* in dogs or cats. But because of the public health risks, particularly in the face of increased populations of immunocompromised people, treatment of mycobacterial (*M. bovis*, *M. tuberculosis*) infections in domestic or captive animals is controversial. In addition, INH has a narrow therapeutic index and toxicity is a concern (see Adverse Effects).

In humans, isoniazid (INH) is routinely used alone to treat latent tuberculosis infections (positive tuberculin skin test) and in combination with other antimycobacterial agents to treat active disease.

Pharmacology/Actions

Isoniazid inhibits the synthesis of mycolic acids, a component of mycobacterial cell walls; its exact mechanism is not well understood. It is most active against mycobacteria that are actively dividing and affects both extracellular and intracellular mycobacteria.

Isoniazid is only active against *M. tuberculosis*, *M. bovis* and some strains of *M. kansasii*. In humans, resistance develops rapidly if used alone against active clinical disease, but not when used for prophylactic treatment.

Pharmacokinetics

No information was located on the pharmacokinetics of INH in dogs or cats.

In humans, isoniazid is rapidly absorbed after oral administration; food can decrease absorption somewhat and INH may undergo significant first pass metabolism. The drug is highly distributed in the body and crosses into the CSF and caseous material. It is distributed into milk and crosses the placenta. It is only slightly (10%) bound to plasma proteins. In humans, the drug is initially primarily acetylated in the liver. The N-acetylated form is then further biotransformed to isonicotinic acid and monoacetylhydrazine.

Monoacetylhydrazine is thought to play a role in the drug's hepatic toxicity. As dogs, like some humans, lack N-acetyltransferase, increased potential for INH toxicity may occur in this species. Elimination half-life in fast acetylators (humans) is 0.5–1.6 hours and 2–5 hours in slow acetylators. Patients with acute or chronic liver disease may have substantially longer half-lives (2X). The drug is mostly eliminated in the urine as inactive metabolites.

Contraindications/Precautions/Warnings

Isoniazid is contraindicated in patients with acute liver disease or those that developed hepatopathy while taking the medication in the past.

It should be used with caution in patients with decreased hepatic function or severe renal disease.

Adverse Effects

The primary adverse effects associated with INH is hepatotoxicity with increased serum liver enzymes. Additional adverse effects reported in dogs include CNS stimulation, peripheral neuropathy and thrombocytopenia. Ataxia, seizures, salivation, diarrhea, vomiting and arrhythmias have been reported after overdoses in dogs. No adverse effect profile for isoniazid was located for cats. In humans, urticaria, hepatotoxicity and peripheral neuropathy are commonly reported; rarely, blood dyscrasias, SLE, and seizures have been reported.

Reproductive/Nursing Safety

Isoniazid crosses the placenta and has been found to be embryocidal in some laboratory species, but teratogenic effects have not been detected in mice, rabbits, or rats. In humans, the FDA categorizes isoniazid as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Isoniazid is excreted in milk in low concentrations (approx. 1–2% of maternal serum concentrations in humans) and it is thought to be safe to use during nursing. Ingested levels via milk are not high enough to serve as prophylaxis for tuberculosis in nursing infants.

Overdosage/Acute Toxicity

Overdosage of INH can be very serious. In dogs, the reported LD₅₀ is 50 mg/kg; serious toxicity can occur with as little as one 300 mg tablet ingested. Ataxia, seizures, salivation, diarrhea, vomiting, acidosis, and arrhythmias have been reported after overdoses in dogs; it is strongly recommended to contact an animal poison control center in the event of any inadvertent ingestion. Treatment may include activated charcoal and drugs such as diazepam or phenobarbital to control seizures. Fluids and acidemia may need correction.

Pyridoxine (Vitamin B-6) has been suggested to be administered intravenously (preferably over 30–60 minutes) on a mg per mg of INH-ingested basis. It is commercially available as a 100 mg/mL 1 mL vial, but it may be difficult to obtain in an emergency situation. A local human hospital may stock it.

Drug Interactions

Drug interactions have not been reported with isoniazid in animals. The following drug interactions have either been reported or are theoretical in humans receiving INH and may be of significance in veterinary patients:

- **ALFENTANIL:** Prolonged alfentanil duration of action
- **ANTACIDS** (especially those containing **aluminum**): Decreased INH absorption

- **BENZODIAZEPINES:** INH may reduce benzodiazepine metabolism
 - **CORTICOSTEROIDS:** May reduce INH efficacy
 - **KETOCONAZOLE:** INH may reduce ketoconazole serum concentrations
 - **OTHER HEPATOTOXIC DRUGS** (e.g., acetaminophen, itraconazole, fluconazole, methimazole, ketoconazole, phenothiazines, sulfonamides, estrogens, etc.): increased risk of hepatotoxicity
 - **OTHER NEUROTOXIC DRUGS:** Increased risk of neurotoxicity
 - **PYRIDOXINE:** INH may antagonize or increase the excretion of pyridoxine, increased pyridoxine may be required; increased peripheral neuritis may occur secondary to pyridoxine/INH interaction
 - **PHENYTOIN:** INH may inhibit metabolism and increase risks for phenytoin toxicity
 - **RIFAMPIN:** Increased risk for hepatotoxicity
 - **THEOPHYLLINE:** Increased risk of theophylline toxicity
- FOOD INTERACTIONS** in humans: **cheese** (Swiss, Cheshire, etc.) or **fish** (Tuna, Skipjack, Sardinella): INH may interfere with metabolism of tyramine and histamine found in fish and cheese

Laboratory Considerations

- INH may cause false-positive **urine glucose determinations** when using cupric sulfate solution (Benedict's Solution, *Clinitest*®); tests utilizing glucose oxidase (*Tes-Tape*®, *Clinistix*®) are not affected

Doses

- **DOGS:**
 - a) For *M. tuberculosis* chemoprophylaxis: 10 mg/kg PO once daily. Drug can be hepatotoxic and dose is extrapolated from human data. Treatment of *M. tuberculosis* or *M. bovis* infections in dogs and cats is not recommended. (Greene and Gunn-Moore 2006)

Monitoring

- Baseline and periodic physical exam, including clinical efficacy and adverse effect queries
- Baseline and periodic: CBC, liver function, renal function

Client Information

- Best to administer on an empty stomach
- If this medication is to be effective, it must be given regularly as directed
- If a dose is missed, do not double the next dose
- Store well out of reach of children or pets; overdoses can be very serious
- Contact veterinarian if any of the following occur: vomiting, decreased appetite/weight loss, diarrhea or loose stools, changes in behavior or activity, yellowing of whites of eyes or mucous membranes, or difficulty running or going up/down stairs

Chemistry/Synonyms

Isoniazid occurs as colorless, or white, odorless crystals. It is freely soluble in water and sparingly soluble in alcohol. It is recommended not to use sugars such as glucose, fructose or sucrose in compounded oral solutions, as a condensation product can be formed that can impair absorption.

Isoniazid may also be known as: INH, INAH, isonicotinic acid hydrazide, isonicotinylhydrazide, isonicotinylhydrazine, or tubazid. INH is available throughout the world in many trade names, some of the more commonly used names include *Isotamine*®, *Laniazid*®, or *Nydrazid*®. **Caution:** *Isopyrin*® is one isoniazid trade name that in some countries contains ramifenazone and not isoniazid.

Storage/Stability

Isoniazid tablets should be stored at temperatures below 40°C, preferably between 15–30°C, in well-closed, light-resistant containers. The oral syrup should be stored at temperatures below 40°C, preferably between 15–30°C, in well-closed, light-resistant containers protected from freezing. The injection should be stored at temperatures below 40°C, preferably between 15–30°C; protected from light and freezing. At low temperatures, crystals may form in the injectable solution; crystals should redissolve upon warming to room temperature.

Dosage Forms/Regulatory Status

ISOPROTERENOL HCL

(eye-soe-proe-ter-e-nole) Isuprel®

BETA-ADRENERGIC AGONIST

Prescriber Highlights

- ▶ **Non-specific beta agonist rarely used for acute bronchial constriction, cardiac arrhythmias (complete AV block), & as adjunctive therapy in shock or heart failure**
- ▶ **Contraindications:** Tachycardias or AV block caused by cardiac glycoside intoxication, ventricular arrhythmias that do not require increased inotropic activity
- ▶ **Caution:** Coronary insufficiency, hyperthyroidism, renal disease, hypertension, or diabetes; not a substitute for adequate fluid replacement in shock
- ▶ **Adverse Effects:** Tachycardia, anxiety, tremors, excitability, headache, weakness, & vomiting; more arrhythmogenic than dopamine or dobutamine
- ▶ **Short duration of activity (including adverse effects)**

Uses/Indications

Isoproterenol is primarily used in veterinary medicine in the treatment of acute bronchial constriction, cardiac arrhythmias (complete AV block) and, occasionally, as adjunctive therapy in shock or heart failure (limited use because of increases in heart rate and ventricular arrhythmogenicity).

Pharmacology/Actions

Isoproterenol is a synthetic beta₁- and beta₂-adrenergic agonist that has no appreciable alpha activity at therapeutic doses. It is thought that isoproterenol's adrenergic activity is a result of stimulating cyclic-AMP production. Its primary actions are increased inotropism and chronotropism, relaxation of bronchial smooth muscle, and peripheral vasodilatation. Isoproterenol may increase perfu-

sion to skeletal muscle (at the expense of vital organs in shock). Isoproterenol will inhibit the antigen-mediated release of histamine and slow releasing substance of anaphylaxis (SRS-A).

Hemodynamic effects noted include decreased total peripheral resistance, increased cardiac output, increased venous return to the heart, and increased rate of discharge by cardiac pacemakers.

Pharmacokinetics

Isoproterenol is rapidly inactivated by the GI tract and metabolized by the liver after oral administration. Sublingual administration is not reliably absorbed and effects may take up to 30 minutes to be seen. Intravenous administration results in immediate effects, but only persists for a few minutes after discontinuation.

It is unknown if isoproterenol is distributed into milk. The pharmacologic actions of isoproterenol are ended primarily through tissue uptake. Isoproterenol is metabolized in the liver and other tissues by catechol-O-methyltransferase (COMT) to a weakly active metabolite.

Contraindications/Precautions/Warnings

Isoproterenol is contraindicated in patients that have tachycardias or AV block caused by cardiac glycoside intoxication. It is also contraindicated in ventricular arrhythmias that do not require increased inotropic activity.

Use isoproterenol with caution in patients with coronary insufficiency, hyperthyroidism, renal disease, hypertension or diabetes. Isoproterenol is not a substitute for adequate fluid replacement in shock.

Adverse Effects

Isoproterenol can cause tachycardia, anxiety, tremors, excitability, headache, weakness, and vomiting. Because of isoproterenol's short duration of action, adverse effects are usually transient and do not require cessation of therapy, but may require lowering the dose or infusion rate. Isoproterenol is considered more arrhythmogenic than either dopamine or dobutamine, so it is rarely used in the treatment of heart failure.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

No specific lactation safety information was found, however, as isoproterenol is rapidly deactivated in the gut, it is unlikely to pose much risk to nursing offspring.

Overdosage/Acute Toxicity

In addition to the signs listed in the Adverse Effects section, high doses may cause an initial hypertension, followed by hypotension as well as tachycardias and other arrhythmias. Besides halting or reducing the drug, treatment is considered to be supportive. Should tachycardias persist, a beta-blocker could be considered for treatment (if patient does not have a bronchospastic disease).

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving isoproterenol and may be of significance in veterinary patients:

- **ANESTHETICS, GENERAL:** An increased risk of arrhythmias developing can occur if isoproterenol is administered to patients who have received cyclopropane or a halogenated hydrocarbon anesthetic agent. Propranolol may be administered should these occur.
- **BETA-BLOCKERS:** May antagonize isoproterenol's cardiac, bronchodilating, and vasodilating effects by blocking the beta effects of isoproterenol. Beta-blockers may be administered to treat the tachycardia associated with isoproterenol use, but use with caution in patient's with bronchospastic disease.
- **DIGOXIN:** An increased risk of arrhythmias may occur if isoproterenol is used concurrently with digitalis glycosides.
- **OXYTOCIC AGENTS:** Hypertension may result if isoproterenol is used with oxytocic agents.
- **SYMPATHOMIMETIC AGENTS, OTHER:** Isoproterenol should not be administered with other sympathomimetic agents (e.g., **phenylpropanolamine**) as increased toxicity may result.
- **THEOPHYLLINE:** Isoproterenol may increase the risk for theophylline toxicity.

Doses

Note: Because of the cardiostimulatory properties of isoproterenol, its parenteral use in human medicine for the treatment of bronchospasm has been largely supplanted by other more beta₂ specific drugs (e.g., terbutaline) and administration methods (nebulization). Use with care.

■ DOGS:

For sinoatrial arrest, sinus bradycardia, complete AV block:

- a) 0.4 mg in 250 mL D₅W drip slowly to effect; or *Isuprel*[®] Glossets 5–10 mg sublingually or rectally q 4–6h (Tilley and Miller 1986)
- b) 0.04–0.08 micrograms/kg/min IV infusion; or 0.1–0.2 mg IM, SC q4h; or 0.4 mg in 250 mL D₅W IV slowly (Morgan 1988)

For bronchodilatation:

- a) 0.1–0.2 mg q6h IM or SC (Papich 1986)

■ CATS:

For sinoatrial arrest, sinus bradycardia, complete AV block:

- a) 0.4 mg in 250 mL D₅W drip slowly to effect (Tilley and Miller 1986)

For feline asthma:

- a) 0.2 mg in 100 mL of D₅W and give IV to effect three times daily; or 0.004–0.006 mg IM q30 minutes as needed (Morgan 1988)

■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

For short-term bronchodilatation:

- a) Dilute 0.2 mg in 50 mL of saline and administer 0.4 micrograms/kg as an IV infusion, monitor heart rate continuously and discontinue when heart rate doubles. Effects may only last for an hour. (Derksen 1987)

Monitoring

- Cardiac rate/rhythm
- Respiratory rate/auscultation during anaphylaxis
- Urine flow if possible
- Blood pressure, and blood gases if indicated and possible

Client Information

- Isoproterenol for injection should be used only by trained personnel in a setting where adequate monitoring can be performed.

Chemistry/Synonyms

Isoproterenol HCl is a synthetic beta-adrenergic agent that occurs as a white to practically white, crystalline powder that is freely soluble in water and sparingly soluble in alcohol. The pH of the commercially available injection is 3.5–4.5.

Isoproterenol HCl may also be known as: isoprenaline hydrochloride, isopropylarterenol hydrochloride, isopropylnoradrenaline hydrochloride, *Imuprel*[®], *Isolin*[®], *Isuprel*[®], *Lenoprel*[®], *Norisodrine Aerotrol*[®], *Proterenal*, *Saventrine*[®], and *Vapo-iso*[®].

Storage/Stability/Compatibility

Store isoproterenol preparations in tight, light-resistant containers. It is stable indefinitely at room temperature. Isoproterenol salts will darken with time upon exposure to air, light, or heat. Sulfites or sulfur dioxide may be added to preparations as an antioxidant. Solutions may become pink or brownish-pink if exposed to air, alkalis, or metals. Do not use solutions that are discolored or contain a precipitate. If isoproterenol is mixed with other drugs or fluids that result in a solution with a pH greater than 6, it is recommended that it be used immediately.

Isoproterenol for injection is reported to be physically **compatible** with all commonly used IV solutions (except 5% sodium bicarbonate), and the following drugs: calcium chloride/gluceptate, cephalothin sodium, cimetidine HCl, dobutamine HCl, heparin sodium, magnesium sulfate, multivitamin infusion, netilmicin sulfate, oxytetracycline HCl, potassium chloride, succinylcholine chloride, tetracycline HCl, verapamil HCl, and vitamin B complex with C.

It is reported to be physically **incompatible** when mixed with: aminophylline or sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Isoproterenol HCl for Injection: 1:5000 solution (0.2 mg/mL) in 1 mL & 5 mL amps; 5 mL & 10 mL vials; *Isuprel*[®] (Sanofi Winthrop); generic; (Rx)

Isoproterenol HCl for Injection: 1:50,000 (0.02 mg/mL) in 10 mL with needle; *Isuprel*[®] (Sanofi Winthrop); (Rx)

ISOSORBIDE DINITRATE ISOSORBIDE MONONITRATE

(eye-soe-sor-bide) Isordil[®], Ismo[®], Imdur[®]

VASODILATOR

Prescriber Highlights

- Limited clinical experience; but may have some utility in small animal medicine for adjunctive treatment of heart failure

Uses/Indications

Isosorbide mononitrate (ISMN) and dinitrate (ISDN) are organic nitrates potentially useful as preload reducing agents in treating heart failure in small animals, however, research and clinical experience demonstrating clinical efficacy are lacking in dogs or cats. Limited research indicates that dogs may require much higher dosages of isosorbide dinitrate to achieve therapeutic effects than do humans.

In humans, isosorbide nitrates are used for treating or preventing angina, treating esophageal spasm, and as an adjunctive treatment in CHF.

Pharmacology/Actions

Organic nitrates (e.g., isosorbide nitrates, nitroglycerin) share a similar pharmacologic profile. They relax vascular smooth muscle causing vasodilation, predominantly on the venous side, but somewhat on arteries/arterioles as well. The mechanism of action is related to their conversion to free radical nitric oxide. Nitric acid is thought to activate guanylate cyclase, thus increasing cyclic GMP and eventually leading to dephosphorylating light chain myosin, causing vasodilation. In humans, nitrates reduce myocardial oxygen demand, but the exact mechanism for this effect is not well understood. Nitrates functionally antagonize the effects of acetylcholine, norepinephrine and histamine. Additionally, nitrates relax all smooth muscle including biliary (including biliary ducts, sphincter of Oddi), bronchial, GI (including the esophagus), ureteral and uterine.

Serum concentrations of isosorbide mononitrate above 100 ng/mL minimum concentration of the drug are believed required for hemodynamic effects in dogs and humans. However, a study (Adin, Kittleson et al. 2001) in both normal dogs and those with CHF, demonstrated no hemodynamic effects (blood pressure, heart rate, PCV, thoracic blood volume percentage, abdominal blood volume percentage) at doses that yielded peak levels as high as $2,352 \pm 701$ ng/mL.

In a study (Nagasawa, Takashima et al. 2003) performed in dogs with experimentally induced mitral regurgitation, oral dosages of a sustained-release isosorbide dinitrate product at 8 mg/kg and above resulted in significant decreases in preload and afterload with increased cardiac output. Effects were sustained for at least 10 hours after dosing.

Pharmacokinetics

In dogs, isosorbide mononitrate oral bioavailability is approximately 70% after oral administration. Oral doses with standard tablets above 2 mg/kg yield peak plasma levels above 100 ng/mL, which is believed to be the minimum concentration of the drug required for hemodynamic effects in dogs and humans. Elimination half-life in dogs with standard tablets is about 1.5 hours. Dogs (24–31 kg BW) given 60 mg sustained-release tablets (*Imdur*®) had peak plasma levels of approximately 550 ng/mL 3 hours after dosing. No pharmacokinetic information was located for cats.

Limited information on isosorbide dinitrate pharmacokinetics in small animals is available; it is reported that pharmacokinetics are similar in dogs and humans. In humans, both isosorbide dinitrate and mononitrate are well absorbed after oral administration. Food may delay the rate, but not the extent, of absorption. Isosorbide dinitrate undergoes extensive first-pass metabolism primarily to isosorbide mononitrate. Isosorbide mononitrate is metabolized primarily in the liver, but does not undergo first pass metabolism. Metabolites do not appear to have pharmacologic activity and are principally excreted in the urine.

Contraindications/Precautions/Warnings

Isosorbide nitrates should not be used in patients in shock or used alone in treating heart failure. Use with extreme caution in patients with low blood pressure or hypovolemia.

Adverse Effects

As there is limited experience in using these drugs in animals an adverse effect profile is not well known.

In humans, the most common adverse effects are headache and postural hypotension. Tachycardia, restlessness or gastrointestinal effects are not uncommon. There have been rare cases of patients who are hypersensitive to organic nitrates.

Reproductive/Nursing Safety

Isosorbide nitrates are probably safe to use at therapeutic dosages during pregnancy. Dose-related increases in embryotoxicity occurred in rabbits given isosorbide dinitrate at 35–150X human dosages and there were some effects noted in rats (litter size, pup survival, prolonged gestation/parturition) given 125X doses of isosorbide mononitrate. Isosorbide mononitrate administered to rats and rabbits at 250 mg/kg/day (75X human dose) demonstrated no untoward effects. In humans, the FDA categorizes isosorbide nitrates as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is unknown if isosorbide nitrates enter milk. Safe use during lactation cannot be guaranteed, but it is unlikely these drugs would pose significant risk to nursing offspring.

Overdosage/Acute Toxicity

Isosorbide mononitrate caused significant lethality in rats and mice at dosages of 2000 mg/kg and 3000 mg/kg, respectively. The primary concerns with an overdosage of isosorbide nitrates would be venous pooling, decreased cardiac output, and hypotension. Treatment is basically supportive; drug therapies with agents such as epinephrine are not recommended. Increasing central fluid volume may be useful but in patients with CHF, must be used with extreme caution.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving isosorbide and may be of significance in veterinary patients:

- **ANTIHYPERTENSIVE DRUGS:** Possible additive hypotensive effects
- **PHENOTHIAZINES:** Possible additive hypotensive effects
- **SELECTIVE PHOSPHODIESTERASE INHIBITORS** (e.g., **sildenafil**): Profound hypotension (use is contraindicated)

Laboratory Considerations

- **Serum cholesterol** levels may be falsely decreased by nitrates when using the Zlatkis-Zak color reaction method

Doses

■ DOGS/CATS:

- a) Cats: For adjunctive treatment of heart failure associated with thyroid storm: Isosorbide dinitrate at 0.5–2 mg/kg PO q8–12h. Start at lowest level and titrate upward. (Ward 2006)
- b) Dogs/Cats: Efficacy is unknown, but isosorbide dinitrate at 0.5–2 mg/kg PO twice daily or isosorbide mononitrate at 0.25–2 mg/kg PO twice daily are occasionally used for refractory heart failure or in combination with hydralazine or amlodipine in patients unable to tolerate ACE inhibitors. It

is unknown if nitrate-free periods are required to prevent nitrate tolerance. (Bulmer and Sisson 2005)

Monitoring

- Clinical efficacy

Client Information

- Inform clients of the limited experience in veterinary medicine with this medication
- May be given with or without meals

Chemistry/Synonyms

To minimize the risk for explosion, dry isosorbide dinitrate is mixed with lactose, mannitol or other inert excipients. To further stabilize the mixture, up to 1% ammonium phosphate or other suitable stabilizer can be used. The resultant dry mixture contains approximately 25% isosorbide dinitrate and is called diluted isosorbide dinitrate. It is an ivory-white, odorless powder that is very slightly soluble in water and sparingly soluble in alcohol.

Undiluted isosorbide mononitrate occurs as a white, crystalline powder that is freely soluble in water or alcohol. It is diluted with lactose or another suitable excipient to stabilize the powder and permit safe handling.

Isosorbide dinitrate may also be known as: ISD, ISDN, EV-151, or sorbide nitrate, *Dilatrate-SR*®, *Isochron*®, *Isordil* and *Titradose*®; many international trade name products are available.

Isosorbide mononitrate may also be known as: AHR-4698, BM-22145, IS-5-MN, or isosorbide-5-mononitrate, *Imdur*®, *Ismo*®, and *Monoker*®; many international trade name products are available.

Storage/Stability

Isosorbide dinitrate oral tablets, chewable tablets, extended-release tablets, and sublingual tablets should be stored in well-closed containers, below 40°C and preferably between 15°–30°C. Heat and moisture accelerates loss of potency.

Isosorbide mononitrate tablets should be stored in tight containers, below 40°C and preferably between 15°–30°C. Isosorbide mononitrate extended-release tablets should be stored in tight containers, between 2°–30°C. Heat and moisture accelerates loss of potency.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance.

HUMAN-LABELED PRODUCTS:

Isosorbide Dinitrate Tablets: 5 mg, 10 mg, 20 mg, 30 mg, & 40 mg; generic, *Isordil Titradose*® (Wyeth); (Rx)

Isosorbide Dinitrate Sublingual Tablets: 2.5 mg, & 5 mg; generic; (Rx)

Isosorbide Dinitrate Extended-Release Tablets: 40 mg; *Isochron*® (Forest); (Rx)

Isosorbide Dinitrate Sustained-Release Capsules: 40 mg; *Dilatrate-SR*® (Schwarz); (Rx)

Isosorbide Mononitrate Tablets: 10 mg, & 20 mg; generic, *Monoker*® (Schwarz), *Ismo*® (Wyeth); (Rx)

Isosorbide Mononitrate Extended-Release Tablets: 30 mg, 60 mg, & 120 mg; generic, *Imdur*® (Key); (Rx)

ISOTRETINOIN

(eye-so-tret-i-noyn) Accutane®

RETINOID

Prescriber Highlights

- Synthetic retinoid that may be useful in treatment a variety of dermatology diseases associated with epithelial cell proliferation & differentiation
- Cautions (risk vs. benefit): Serum hypertriglyceridemia, hypersensitivity to drug; known teratogen
- Adverse Effects: Most common adverse effect seen in dogs is keratoconjunctivitis sicca (KCS); apparently not a problem in cats. Other potential adverse effects in small animals include: GI effects (anorexia, vomiting, abdominal distention), CNS effects (lassitude, hyperactivity, collapse), pruritus, erythema of feet & mucocutaneous junctions, polydipsia, swollen tongue
- Obtaining the medication for veterinary patients may be difficult
- Pregnant women should avoid contact with medication

Uses/Indications

Isotretinoin may be useful in treating a variety of dermatologic-related conditions, including canine lamellar ichthyosis, cutaneous T-cell lymphoma, intracutaneous cornifying epitheliomas, multiple epidermal inclusion cysts, comedo syndrome in Schnauzers, and sebaceous adenitis seen in standard poodles.

Because of the concerns of teratogenic effects in humans, availability to veterinarians may be restricted by the manufacturers and drug distributors; obtaining the medication for veterinary patients may be difficult.

Pharmacology/Actions

A retinoid, isotretinoin's major pharmacologic effects appear to be regulation of epithelial cell proliferation and differentiation. It affects monocyte and lymphocyte function, which can cause changes in cellular immune responses. The effects on skin include reduction of sebaceous gland size and activity, thereby reducing sebum production. It also has anti-keratinization and antiinflammatory activity and may indirectly reduce bacterial populations in sebaceous pores.

Pharmacokinetics

Isotretinoin is rapidly absorbed from the gut once the capsule disintegrates and the drug is dispersed in the GI contents. This may require up to 2 hours after dosing. Animal studies have shown that only about 25% of a dose reaches the systemic circulation, but food or milk in the gut may increase this amount. Isotretinoin is distributed into many tissues, but is not stored in the liver (unlike vitamin A). It crosses the placenta and is highly bound to plasma proteins. It is unknown if it enters milk. Isotretinoin is metabolized in the liver and is excreted in the urine and feces. In humans, terminal half-life is about 10–20 hours.

Contraindications/Precautions/Warnings

Isotretinoin should only be used when the potential benefits outweigh the risks when the following conditions exist: hypertriglyceridemia or sensitivity to isotretinoin.

Isotretinoin is a known teratogen. Major anomalies have been reported in children of women taking the medication and it is not advised to use the medication in households where pregnant women are present.

Adverse Effects

There appears to be a low incidence of adverse effects, particularly in dogs. The most common adverse effect seen in dogs is keratoconjunctivitis sicca (KCS). This apparently is not a problem in cats. Other potential adverse effects include: GI effects (anorexia, vomiting, diarrhea, abdominal distention), CNS effects (lassitude, hyperactivity, behavioral changes, collapse), stiffness of limbs, pruritus, exfoliative dermatitis, erythema of feet and mucocutaneous junctions/cheilitis, polydipsia, and swollen tongue.

Incidence of adverse effects may be higher in cats. Effects reported include: blepharospasm, periocular crusting, erythema, diarrhea and, especially, weight loss secondary to anorexia. If cats develop adverse effects, the time between doses may be prolonged (e.g., every other week give every other day) to reduce the total dose given.

Reproductive/Nursing Safety

Isotretinoin is a known teratogen. Major anomalies have been reported in children of women taking the medication. It is absolutely contraindicated in pregnant veterinary patients as well. Isotretinoin also appears to inhibit spermatogenesis. In humans, the FDA categorizes this drug as category X for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*)

It is not known whether this drug is excreted in breast milk. At this time, it is not recommended for use in nursing mothers.

Overdosage/Acute Toxicity

There were 129 exposures to isotretinoin reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 126 were dogs with 5 showing clinical signs and the remaining 4 reported cases were cats with no clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, diarrhea, and lethargy. Because of the drug's potential adverse effects, gut emptying should be considered with acute overdoses when warranted.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving isotretinoin and may be of significance in veterinary patients:

- **VITAMIN A or OTHER RETINOIDS:** Isotretinoin used with other retinoids (**etretinate**, **tretinoin**, or **vitamin A**) may cause additive toxic effects.
- **TETRACYCLINES:** Use with tetracyclines may increase the potential for the occurrence of pseudotumor cerebri (cerebral edema and increased CSF pressure).

Laboratory Considerations

- Increases in serum **triglyceride** and **cholesterol** levels may be noted which can be associated with corneal lipid deposits
- **Platelets** may be increased
- **ALT** (SGOT), **AST** (SGPT), and **LDH** levels may be increased

Doses

■ DOGS:

- a) For sebaceous adenitis when more conservative treatments have failed: 1 mg/kg PO q12h for one month; if improvement is noted reduce dose to 1 mg/kg PO once daily; long-term

goal is to treat with either 1 mg/kg PO every other day or 0.5 mg/kg once daily (Rosser 1992)

- b) For sebaceous adenitis: 1–3 mg/kg PO once a day to twice daily (Bloom 2006c)
- c) For treatment of Schnauzer comedo syndrome: 1 mg/kg once daily or divided q12h PO;
For sebaceous adenitis in poodles; granulomatous sebaceous adenitis in vizslas: 1–2 mg/kg once daily or divided q12h PO;
For epitheliotrophic lymphoma, cutaneous lymphoma: 2 mg/kg once daily or divided q12h PO (Power and Ihrke 1995)
- d) For schnauzer comedo syndrome, sebaceous adenitis in poodles, ichthyosis, keratocanthoma, epitheliotrophic lymphoma, and sebaceous gland hyperplasia and adenoma: 1–3 mg/kg q12–24h PO (Kwochka 2003b)
- e) For cutaneous lymphosarcoma: Isotretinoin at 3–4 mg/kg PO daily. Prednisone (1 mg/kg/day) may be useful to alleviate pruritus. Lomustine at 50 mg/m² q21–30 days may be effective (see lomustine monograph for more information) (White 2005c)

■ CATS:

For feline acne:

- a) 5 mg/kg PO once daily (Hall and Campbell 1994)
 - b) 10 mg per cat once daily PO (Power and Ihrke 1995)
 - c) 1–3 mg/kg q12–24h PO (Kwochka 2003b)
- For epitheliotrophic lymphoma, cutaneous lymphoma:
- a) 10 mg/cat once daily PO (Power and Ihrke 1995)

Monitoring

See Lab Considerations and Adverse Effects.

- Efficacy
- Liver function tests (baseline and if signs appear)
- Dogs: Schirmer Tear tests (monthly—especially in older dogs)
- Cats: Weight

Client Information

- Isotretinoin should not be handled by pregnant females and use in households with pregnant women present is ill advised. Veterinarians must take the personal responsibility to educate clients of the potential risk of ingestion by pregnant females.
- Milk or high fat foods will increase the absorption of isotretinoin. To reduce variability of absorption, either have clients consistently give with meals or not.
- Long-term therapy can be quite expensive.

Chemistry/Synonyms

A synthetic retinoid, isotretinoin occurs as a yellow-orange to orange, crystalline powder. It is insoluble in both water and alcohol. Commercially, it is available in soft gelatin capsules as a suspension in soybean oil.

Isotretinoin may also be known as: isotretinoinum, 13-cis-retinoic acid, Ro-4-3780, Accure®, Accutane®, Accutin®, Amnesteem®, Claravis®, Curatane®, Isoacne®, Isohexal®, Isotrex®, Liderma®, Nimegen®, Oratane®, Procuta®, Roaccutan®, Roaccutane®, Roacutan®, Sotret®, Stiefotrex®, and Tretin®.

Storage/Stability/Compatibility

Capsules should be stored at room temperature in tight, light resistant containers. The drug is photosensitive and will degrade with light exposure. Expiration dates of 2 years are assigned after manufacture.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None**HUMAN-LABELED PRODUCTS:**

Isotretinoin Capsules: 10 mg, 20 mg, 30 mg & 40 mg (regular & soft gel); *Accutane*® (Roche); *Claravis*® (Barr Laboratories); *Amnesteem*® (Bertek); *Sotret*® (Ranbaxy); (Rx)

Note: Because of the concerns of teratogenic effects in humans, availability to veterinarians may be restricted by the manufacturers and drug distributors; obtaining the medication for veterinary patients may be difficult.

ISOXSUPRINE HCL

(eye-sox-suh-reen) Vasodilan®

Prescriber Highlights

- ▶ Peripheral vasodilator that may have some efficacy in treatment of navicular disease in horses; efficacy in doubt when used orally
- ▶ May be beneficial for Raynaud's-like syndrome in dogs
- ▶ Contraindications: Immediately post-partum or in the presence of arterial bleeding
- ▶ Adverse Effects: After injection, CNS stimulation (uneasiness, hyperexcitability, nose-rubbing) or sweating. Adverse effects are unlikely after oral administration.

Uses/Indications

Isoxsuprine is used in veterinary medicine principally for the treatment of navicular disease in horses; however, recent studies have shown disappointing efficacy when used orally. It has been used in humans for the treatment of cerebral vascular insufficiency, dysmenorrhea, and premature labor, but efficacies are unproven for these indications.

There has been an anecdotal report of isoxsuprine being helpful for treating dogs with a Raynaud's-like syndrome (periodic digital cyanosis, onychogryphosis) (Carlotti 2002).

Pharmacology/Actions

Isoxsuprine causes direct vascular smooth muscle relaxation primarily in skeletal muscle. While it stimulates beta-adrenergic receptors it is believed that this action is not required for vasodilatation to occur. In horses with navicular disease, isoxsuprine will raise distal limb temperatures significantly. Isoxsuprine will relax uterine smooth muscle and may have positive inotropic and chronotropic effects on the heart. At high doses, isoxsuprine can decrease blood viscosity and reduce platelet aggregation.

Pharmacokinetics

In humans, isoxsuprine is almost completely absorbed from the GI tract, but in one study that looked at the cardiovascular and pharmacokinetic effects of isoxsuprine in horses (Mathews and et 1986), bioavailability was low after oral administration, probably due to a high first-pass effect. After oral dosing of 0.6 mg/kg, the drug was non-detectable in plasma and no cardiac changes were detected. This study did not evaluate cardiovascular effects in horses with navicular disease, nor did it attempt to measure changes in distal limb blood flow. After IV administration in horses, the elimination half-life is between 2.5–3 hours.

Contraindications/Precautions/Warnings

Isoxsuprine should not be administered to animals immediately post-partum or in the presence of arterial bleeding.

Adverse Effects

After parenteral administration, horses may show signs of CNS stimulation (uneasiness, hyperexcitability, nose-rubbing) or sweating. Adverse effects are unlikely after oral administration, but hypotension, tachycardia, and GI effects are possible.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

No specific lactation safety information was found.

Overdosage/Acute Toxicity

Serious toxicity is unlikely in horses after an inadvertent oral overdose, but signs listed in the Adverse Effects section could be seen. Treat signs if necessary. CNS hyperexcitability could be treated with diazepam, and hypotension with fluids.

Drug Interactions

No clinically significant drug interactions have been reported for this agent.

Laboratory Considerations

None were noted

Doses■ **HORSES:** (Note: ARCI UCGFS Class 4 Drug)

For treatment of orthopedic conditions, such as navicular disease:

- a) For long break-over if therapeutic shoeing does not correct: Initially, 1.2 mg/kg PO q8h for 3 weeks. The dose is decreased as soundness improves, to 1.2 mg/kg PO once daily for 6 weeks, then every other day until heel first landing occurs. Phenylbutazone is added if lameness is greater than grade II on a scale of I–V, or until recheck occurs.

To increase the circulation to the podotrochlea: 0.6–1.2 mg/kg twice daily until sound, then decreased to once daily for 2 weeks then further decreased to every other day. The drug is classified as a “blocking” agent by the AHSA. (Turner 1999)

- b) 0.6–2 mg/kg PO q12h (Brumbaugh, Lopez et al. 1999)

As a tocolytic agent:

- a) 0.4–0.6 mg/kg IM or PO twice daily. Efficacy is unproven and oral bioavailability appears highly variable. (Wilkins 2004b)

■ **DOGS:**

For treatment of “Raynaud-like” disease:

- a) 1 mg/kg/day PO (Carlotti 2002),

Monitoring

- Clinical efficacy
- Adverse effects (tachycardia, GI disturbances, CNS stimulation)

Client Information

- To be maximally effective, doses must be given routinely as directed.
- Tablets may be crushed and made into a slurry, suspension, or paste by adding corn syrup, cherry syrup, etc., just before administration.

Chemistry/Synonyms

A peripheral vasodilating agent, isoxsuprine occurs as an odorless, bitter-tasting, white, crystalline powder with a melting point of about 200°C. It is slightly soluble in water and sparingly soluble in alcohol.

Isoxsuprine HCl may also be known as: Caa-40, isoxsuprini hydrochloridum, phenoxyisopropylisoxsuprifen, *Dilum*®, *Duvadilan*®, *Fadaespaamol*®, *Fenam*®, *Inibina*®, *Isodilan*®, *Isotenk*®, *Uterine*®, *Vadosilan*®, *Vasodilan*®, *Vasolan*®, *Vasosuprina Ilfi*®, *Voxsuprine*®, and *Xuprin*®.

Storage/Stability

Tablets should be stored in tight containers at room temperature (15–30°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Isoxsuprine HCl Tablets: 10 mg & 20 mg; *Vasodilan*® (Mead Johnson); *Voxsuprine*® (Major); generic; (Rx)

ITRACONAZOLE

(ey-tra-kon-a-zole) Sporanox®

ANTIFUNGAL

Prescriber Highlights

- ▶ Synthetic oral triazole antifungal used for systemic mycoses, including aspergillosis, cryptococcal meningitis, blastomycosis, & histoplasmosis
- ▶ Not amenable to compounding; be wary of compounded itraconazole dosage forms as bulk powder itraconazole may not be absorbed
- ▶ Contraindications (relative: risk vs. benefit): Hypersensitivity to it or other azole antifungal agents, hepatic impairment, or achlorhydria (or hypochlorhydria)
- ▶ Adverse Effects: DOGS: anorexia is the most common, but hepatic toxicity most significant adverse effect. At the higher dosage rate, some develop ulcerative skin lesions/vasculitis & limb edema. Rare, serious erythema multiforme or toxic epidermal necrolysis
- ▶ Adverse Effects: CATS: Dose related; GI effects (anorexia, weight loss, vomiting), hepatotoxicity (increased ALT, jaundice), & depression
- ▶ May be more efficacious than ketoconazole, but is also more expensive; long-term treatment may be required
- ▶ Maternotoxicity, fetotoxicity, & teratogenicity in lab animals at high dosages (5–20 times labeled)
- ▶ Drug interactions

Uses/Indications

Itraconazole may have use in veterinary medicine in the treatment of systemic mycoses, including aspergillosis, cryptococcal meningitis, blastomycosis, and histoplasmosis. Itraconazole is probably more effective than ketoconazole, but is significantly more expensive. It may also be useful for superficial candidiasis or dermato-

phytosis. Itraconazole does not have appreciable effects (unlike ketoconazole) on hormone synthesis and may have fewer side effects than ketoconazole in small animals.

It is considered by many to be the drug of choice for treating blastomycosis, unless moderate or severe hypoxemia is present (than amphotericin B).

In horses, itraconazole may be useful in the treatment of sporotrichosis and *Coccidioides immitis* osteomyelitis.

Pharmacology/Actions

Itraconazole is a fungistatic triazole compound. Triazole-derivative agents, like the imidazoles (clotrimazole, ketoconazole, etc.), presumably act by altering the cellular membranes of susceptible fungi, thereby increasing membrane permeability and allowing leakage of cellular contents and impaired uptake of purine and pyrimidine precursors. Itraconazole has efficacy against a variety of pathogenic fungi, including yeasts and dermatophytes. *In vivo* studies using laboratory models have shown that itraconazole has fungistatic activity against many strains of *Candida*, *Aspergillus*, *Cryptococcus*, *Histoplasma*, *Blastomyces*, and *Trypanosoma cruzi*.

Itraconazole has immune-suppressing activity, probably via suppressing T-lymphocyte proliferation.

Pharmacokinetics

Itraconazole absorption is highly dependent on gastric pH and presence of food. When given on an empty stomach, bioavailability may only be 50% or less; with food, it may approach 100%. In cats, the oral solution is more bioavailable and probably has fewer GI effects. The commercially available capsules are specially formulated to increase oral bioavailability. Compounding capsules from bulk powders may not yield a dosage form that is absorbed. The commercially available liquid preparation possesses adequate oral bioavailability.

Itraconazole has very high protein binding and is widely distributed throughout the body, particularly to tissues high in lipids (drug is highly lipophilic). Skin, sebum, female reproductive tract, and pus all have concentrations greater than those found in the serum. Only minimal concentrations are found in CSF, urine, aqueous humor, and saliva. However, many fungal infections in the CNS, eye, or prostate can be effectively treated with itraconazole.

Itraconazole is metabolized by the liver to many different metabolites, including to hydroxyitraconazole, which is active. In humans, itraconazole's serum half-life ranges from 21–64 hours. Elimination may be a saturable process. Because of its long half-life, itraconazole does not reach steady state plasma levels for at least 6 days after starting therapy. If loading doses are given, levels will approach those of steady-state sooner.

Contraindications/Precautions/Warnings

Itraconazole should not be used in patients hypersensitive to it or other azole antifungal agents.

Use itraconazole in patients with hepatic impairment or achlorhydria (or hypochlorhydria) only when the potential benefits outweigh the risks.

Compounding capsules from bulk powders may not yield a dosage form that is absorbed.

Adverse Effects

In dogs, anorexia is the most common adverse effect seen, especially at higher dosages, but hepatic toxicity appears to be the most significant adverse effect. Approximately 10% of dogs receiving 10 mg/kg/day and 5% of dogs receiving 5 mg/kg/day developed hepatic toxicosis serious enough to discontinue treatment (at least temporarily). Hepatic injury is determined by an increased ALT activity. Anorexia is often the symptomatic marker for toxicity and usually

occurs in the second month of treatment. Some dogs (7%) given itraconazole at the higher dosage rate (10 mg/kg/day) may develop ulcerative skin lesions/vasculitis and limb edema that may require dosage reduction. These generally resolve following drug discontinuation. Rarely, serious erythema multiforme or toxic epidermal necrolysis reactions have been noted.

In cats, adverse effects appear to be dose related. GI effects (anorexia, weight loss, vomiting), hepatotoxicity (increased ALT, jaundice) and depression have been noted. Should adverse effects occur and ALT is elevated, the drug should be discontinued. Increased liver enzymes in the absence of other signs do not necessarily mandate dosage reduction or drug discontinuation. Once ALT levels return to normal and other adverse effects have diminished, if necessary, the drug may be restarted at a lower dosage or use longer dosing intervals with intense monitoring.

Reproductive/Nursing Safety

In laboratory animals, itraconazole has caused dose-related maternotoxicity, fetotoxicity and teratogenicity at high dosages (5–20 times labeled). As safety has not been established, use only when the benefits outweigh the potential risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Itraconazole does enter maternal milk; significance is unknown.

Overdosage/Acute Toxicity

There is very limited information on the acute toxicity of itraconazole. Giving oral antacids may help reduce absorption. If a large overdose occurs, consider gut emptying and give supportive therapy as required. Itraconazole is not removed by dialysis.

In chronic toxicity studies, dogs receiving 40 mg/kg PO daily for 3 months demonstrated no overt toxicity.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving itraconazole and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Lab animal studies have shown that itraconazole used concomitantly with amphotericin B may be antagonistic against *Aspergillus* or *Candida*; the clinical importance of these findings is not yet clear
- **ANTACIDS:** May reduce oral absorption of itraconazole; administer itraconazole at least 1 hour before or 2 hours after antacids
- **BENZODIAZEPINES (alprazolam, diazepam, midazolam, triazolam):** Itraconazole may increase levels
- **BUSPIRONE:** Plasma concentrations may be elevated
- **BUSULFAN:** Itraconazole may increase levels
- **CALCIUM-CHANNEL BLOCKING AGENTS (amlodipine, verapamil):** Itraconazole may increase levels
- **CISAPRIDE:** Itraconazole may increase cisapride levels and possibility for toxicity; use together contraindicated in humans
- **CORTICOSTEROIDS:** Itraconazole may inhibit the metabolism of corticosteroids; potential for increased adverse effects
- **CYCLOPHOSPHAMIDE:** Itraconazole may inhibit the metabolism of cyclophosphamide and its metabolites; potential for increased toxicity
- **CYCLOSPORINE:** Increased cyclosporine levels
- **DIGOXIN:** Itraconazole may increase digoxin levels; use together considered contraindicated in humans
- **FENTANYL/ALFENTANIL:** Itraconazole may increase fentanyl or alfentanil levels

- **H₂-BLOCKERS (ranitidine, famotidine, etc.):** Increased gastric pH may reduce itraconazole absorption
- **IVERMECTIN:** Itraconazole may increase risk for neurotoxicity
- **MACROLIDE ANTIBIOTICS (erythromycin, clarithromycin):** May increase itraconazole concentrations
- **PHENOBARBITAL/PHENYTOIN:** May decrease itraconazole levels
- **PROTON-PUMP INHIBITORS (omeprazole, etc.):** Increased gastric pH may reduce itraconazole absorption
- **QUINIDINE:** Itraconazole may increase digoxin levels; use together considered contraindicated in humans
- **RIFAMPIN:** May decrease itraconazole levels; itraconazole may increase rifampin levels
- **SULFONYLUREA ANTIDIABETIC AGENTS (e.g., glipizide, glyburide):** Itraconazole may increase levels; hypoglycemia possible
- **VINCISTINE/VINBLASTINE:** Itraconazole may inhibit vinca alkaloid metabolism and increase levels
- **WARFARIN:** Itraconazole may cause increased prothrombin times in patients receiving warfarin or other coumarin anticoagulants

Laboratory Considerations

- Itraconazole may cause **hypokalemia** or increases in **liver function tests** in a small percentage of patients.

Doses

■ DOGS:

For systemic mycoses:

- a) For *Malassezia* dermatitis: 5–10 mg/kg PO once daily (Muse 2000)
- b) Pulse therapy for *Malassezia* dermatitis: 5 mg/kg for 2 consecutive days per week for 3 weeks (Foil 2003a)
- c) For dermatophytosis: 5 mg/kg PO once daily. Prolonged course of therapy required. Begin taking cultures after 4 weeks of treatment. Continue therapy for 2 weeks beyond clinical cure and when 2–3 negative cultures are obtained at weekly intervals. (Frank 2000)
- d) For dermatophytosis: 5 mg/kg PO once daily on an every other week schedule. Treatment is generally continued for three “pulses” of one week on, one week off. Toxicity problems are rare with this protocol. (DeBoer 2006)
- e) For Blastomycosis: 5 mg/kg PO once daily for at least 30 days after all signs of disease have resolved (treatment must persist for at least 60–90 days). Give with food.
For Nasal Aspergillosis: 5 mg/kg pO twice daily for at least 90 days. Because of expense, larger dogs may require a more cost effective treatment such as 1% topical clotrimazole in nasal passages and sinuses. (Davidson and Mathews 2000)
- f) For Histoplasmosis: 10 mg/kg daily PO; given with food; if dog has intestinal histoplasmosis, treat with amphotericin B (0.5 mg/kg IV over 3–4 hours in D5W every other day) initially. Usually after six doses of amphotericin B, may switch to itraconazole. Total treatment times (amphotericin B and itraconazole) should be for at least 30 days after all signs of disease have resolved (treatment must persist for at least 90 days). (Legendre and Toal 2000)
- g) For Blastomycosis: 5 mg/kg PO once a day or divided twice a day. Continue for 2–3 months or until active disease is not apparent. A loading dose of 10 mg/kg once a day (or divided twice a day) for the first three days may reduce the “lag” phase of effectiveness.

For coccidiomycosis: 5–10 mg/kg PO once daily; may need to treat for 6–12 months (Taboada 2000)

- h) For sporotrichosis: 5–10 mg/kg once daily for 30 days beyond complete resolution of detectable lesions.

For pythiosis or lagendiosis (after lesion resection): 10 mg/kg PO once daily (with terbinafine at 5–10 mg/kg PO q24h) for at least 2 months after surgery.

For zygomycosis (after aggressive surgical resection: 5–10 mg/kg PO q24h. For non-resectable lesions, either itraconazole for 3–6 months or amphotericin B lipid complex. Recurrence is possible with either surgical or medical therapy. (Grooters 2005)

■ CATS:

For susceptible systemic mycoses:

- a) For Histoplasmosis: 10 mg/kg daily PO; given with food
For Cryptococcosis: 50–100 mg per cat per day PO for many months. Mean treatment time is 8.5 months. If response inadequate, may add flucytosine (at 100–125 mg/kg divided into three doses per day). (Legendre and Toal 2000)

- b) For Blastomycosis: 10 mg/kg PO once a day or divided twice a day. Continue for 2–3 months or until active disease is not apparent (**Note:** cats usually require longer treatment than dogs)

For Histoplasmosis: 10 mg/kg once daily or divided twice daily PO; at least 2–4 months of treatment required

For coccidiomycosis: 5–10 mg/kg PO once daily; may need to treat for 6–12 months (Taboada 2000)

- c) For sporotrichosis: 5–10 mg/kg once daily for 30 days beyond complete resolution of detectable lesions. (Grooters 2005)

- d) For Cryptococcosis: For mild to moderate disease where cats are eating and do not have CNS involvement: Cats weighing 3.5 kg or less receive 50 mg PO once daily or 100 mg PO every other day; medium to large cats get 100 mg PO once daily. Give with food; may be mixed with tasty food treat. Monitor ALT; itraconazole hepatotoxicity is reversible upon discontinuation of the drug and it can usually be restarted safely at 50% of the original dose. Continue treatment until cat appears completely normal; generally takes 3–12 months. Then obtain serum sample to determine decline in antigen titer. A 4–5 fold reduction suggests successful therapy. Then restart therapy (possibly at a reduced dose) or change to ketoconazole (50 mg/day) until antigen level declines to zero. (Malik 2006b)

For generalized dermatophytosis:

- a) 10 mg/kg PO once daily; prolonged course of therapy required. Begin taking cultures after 4 weeks of treatment. Continue therapy for 2 weeks beyond clinical cure and when 2–3 negative cultures are obtained at weekly intervals. (Frank 2000)

- b) 5 mg/kg PO twice daily or 10 mg/kg with food. Give until culture is negative 2 times at two week intervals; generally 3–5 weeks. Open capsule and measure out calculated portion; give in butter or *a/d*®. Can be stored in the freezer.

Pulse therapy: 5 mg/kg PO for 2 consecutive days per week, increasing interval gradually is useful in the management of dermatophytosis in longhaired cats and in cats in a heavily contaminated environment.

For dermatophyte granuloma (TOC): 10 mg/kg PO once daily for weeks to months, at least one month beyond clinical resolution and until brush culture is negative x 2. (Foil 2003b)

- c) For dermatophytosis: 5 mg/kg PO once daily on an every other week schedule. Treatment is generally continued for three “pulses” of one week on, one week off. Toxicity problems are rare with this protocol. (DeBoer 2006)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Mice: For blastomycosis: 50–150 mg/kg q24h; Rats: For vaginal candidiasis: 2.5–10 mg/kg q24h; Guinea pigs: 5 mg/kg q24h for systemic candidiasis (Adamcak and Otten 2000)

■ HORSES:

For aspergillosis:

- a) 3 mg/kg twice a day (Legendre 1993)

■ BIRDS:

- a) Ratites: 6–10 mg/kg PO once daily; if neuro signs develop reduce dose or discontinue (Jenson 1998)

- b) 10–20 mg/kg PO q12–24h (based upon extrapolation from mammalian kinetics). Use with caution in African grey parrots. (Flammer 2003a)

Monitoring

■ Clinical Efficacy

■ With long-term therapy, routine liver function tests are recommended (monthly ALT)

■ Appetite

■ Physical assessment for ulcerative skin lesions in dogs

Client Information

■ Compliance with treatment recommendations must be stressed

■ Have clients report any potential adverse effects

■ Give with food

■ Do not give with any other medications without veterinarian's approval

Chemistry/Synonyms

A synthetic triazole antifungal, itraconazole is structurally related to fluconazole. It has a molecular weight of 706 and a pKa of 3.7.

Itraconazole may also be known as: itraconazolum, oriconazole, R-51211, or *Sporanox*®; many other trade names are available.

Storage/Stability/Compatibility

Itraconazole capsules should be stored between 15–25°C and protected from light and moisture.

Itraconazole oral solution should be stored at temperatures less than 26°C, and protected from freezing.

Itraconazole for injection should be stored at temperatures less than 26°C, and protected from light and freezing. After diluting with the 0.9% sodium chloride injection supplied, the resulting solution may be stored at 2–8°C or 15–25°C for up to 48 hours. Protect solution from light during storage. It may be exposed to normal room light during administration.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Itraconazole Capsules: 100 mg; *Sporanox*® (Janssen-Ortho); generic; (Rx)

Itraconazole Oral Solution: 10 mg/mL in 150 mL; *Sporanox*® (Ortho Biotech); (Rx)

Itraconazole Injectable Solution: 10 mg/mL in Kits of 25 mL amps, & 50 mL bags of 0.9% NaCl Injection and 1 filtered infusion set; *Sporanox*® (Ortho Biotech); (Rx)

IVERMECTIN

(eye-ver-mek-tin) Heartgard®, Ivomec®

ANTIPARASITIC

Prescriber Highlights

- ▶ **Prototype avermectin drug used in variety of species as an antiparasiticide**
- ▶ **Contraindications:** Label specific due to lack of safety data (foals, puppies, etc.) or public health safety (lactating dairy animals)
- ▶ **Caution in breeds susceptible to MDR1-allele mutation** (Collies, Australian Shepherds, Shelties, Long-haired Whippet, "white feet"); at higher risk for CNS toxicity
- ▶ **Adverse Effects:** **HORSES:** Swelling & pruritus at the ventral mid-line can be seen approximately 24 hours after ivermectin administration due to a hypersensitivity reaction to dead *Onchocerca* spp. microfilaria. **DOGS:** May exhibit a shock-like reaction when ivermectin is used as a microfilaricide, presumably due to a reaction associated with the dying microfilaria. **CATTLE:** Ivermectin can induce serious adverse effects by killing the larva when they are in vital areas; may also cause discomfort or transient swelling at the injection site. **MICE & RATS:** May cause neurologic toxicity at doses slightly more than usually prescribed. **BIRDS:** Death, lethargy, or anorexia may be seen. **Orange-cheeked Waxbill Finches & budgerigars** may be more sensitive to ivermectin than other species

Uses/Indications

Ivermectin is approved in horses for the control of: large strongyles (adult) (*Strongylus vulgaris*, *S. edentatus*, *S. equinus*, *Triodontophorus* spp.), small strongyles, pinworms (adults and 4th stage larva), ascarids (adults), hairworms (adults), large-mouth stomach worms (adults), neck threadworms (microfilaria), bots (oral and gastric stages), lungworms (adults and 4th stage larva), intestinal threadworms (adults), and summer sores (cutaneous 3rd stage larva) secondary to *Hebronema* or *Draschia* Spp.

In cattle, ivermectin is approved for use in the control of gastrointestinal roundworms (adults and 4th stage larva), lungworms (adults and 4th stage larva), cattle grubs (parasitic stages), sucking lice, and mites (scabies). For a listing of individual species covered, refer to the product information.

In swine, ivermectin is approved for use to treat GI roundworms, lungworms, lice, and mange mites. For a listing of individual species covered, refer to the product information.

In reindeer, ivermectin is approved for use in the control of warbles.

In American Bison, ivermectin is approved for use in the control of grubs.

In dogs and cats, ivermectin is approved only for use as a preventative for heartworm. It has also been used as a microfilaricide, slow-kill adulticide, ectoparasiticide, and endoparasiticide.

Pharmacology/Actions

Ivermectin enhances the release of gamma amino butyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks the post-synaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. By stimulating the release of GABA, ivermectin causes paralysis of the

parasite and eventual death. As liver flukes and tapeworms do not use GABA as a peripheral nerve transmitter, ivermectin is ineffective against these parasites.

Pharmacokinetics

In simple-stomached animals, ivermectin is up to 95% absorbed after oral administration. Ruminants only absorb $\frac{1}{4}$ – $\frac{1}{3}$ of a dose due to inactivation of the drug in the rumen. While there is greater bioavailability after SC administration, absorption after oral dosing is more rapid than SC. It has been reported that ivermectin's bioavailability is lower in cats than in dogs, necessitating a higher dosage for prophylaxis of heartworm in this species.

Ivermectin is well distributed to most tissues, but does not readily penetrate into the CSF, thereby minimizing its toxicity. Collie-breed dogs with a specific gene defect allow more ivermectin into the CNS than other breeds/species.

Ivermectin has a long terminal half-life in most species (see below). It is metabolized in the liver via oxidative pathways and is primarily excreted in the feces. Less than 5% of the drug (as parent compound or metabolites) is excreted in the urine.

Pharmacokinetic parameters of ivermectin have been reported for various species:

Cattle: Volume of distribution = 0.45–2.4 L/kg; elimination half-life = 2–3 days; total body clearance = 0.79 L/kg/day.

Dogs: Bioavailability = 0.95; volume of distribution = 2.4 L/kg; elimination half-life = 2 days.

Swine: Volume of distribution = 4 L/kg; elimination half-life = 0.5 days.

Sheep: Bioavailability = 1 (intra-abomasal), 0.25 (intra-ruminal); volume of distribution = 4.6 L/kg; elimination half-life = 2–7 days.

Contraindications/Precautions/Warnings

The manufacturer recommends that ivermectin not be used in foals less than 4 months old, as safety of the drug in animals this young has not been firmly established. However, foals less than 30 days of age have tolerated doses as high as 1 mg/kg without signs of toxicity.

Ivermectin is not recommended for use in puppies less than 6 weeks old. After receiving heartworm prophylaxis doses, the manufacturer recommends observing Collie-type breeds for at least 8 hours after administration. Most clinicians feel that ivermectin should not be used in breeds susceptible (Collies, Shelties, Australian shepherds, etc.) to the *mdr1* gene mutation at the doses specified for treating microfilaria or other parasites unless the patient has been tested and found not to have the gene defect. A specific test for identifying dogs that have the gene defect (deletion mutation of the *mdr1* gene) is now available. Contact the veterinary clinical pharmacology lab at www.vetmed.wsu.edu.

Ivermectin is reportedly contraindicated in chelonian species.

Because milk withdrawal times have not been established, the drug is not approved for use in lactating dairy animals or females of breeding age.

The injectable products for use in cattle and swine should be given subcutaneously only; do not give IM or IV.

If using a product in a species not labeled for that product (extra-label), be certain of the dosage and/or dilutions. There are many reports of overdoses in small animals when large animal products have been used.

Adverse Effects

In horses, swelling and pruritus at the ventral mid-line can be seen approximately 24 hours after ivermectin administration due to a hypersensitivity reaction to dead *Onchocerca* spp. microfilaria. The reaction is preventable by administering a glucocorticoid just prior

to, and for 1–2 days after ivermectin. If untreated, swelling usually subsides within 7–10 days and pruritus will resolve within 3 weeks.

Dogs may exhibit a shock-like reaction when ivermectin is used as a microfilaricide, presumably due to a reaction associated with the dying microfilaria. Other adverse effects when used as a microfilaricide include depression, hypothermia, and vomiting. Pretreatment with diphenhydramine (2 mg/kg IM) and dexamethasone (0.25 mg/kg IV) can help prevent adverse reactions (Atkins 2005).

When used to treat *Hypoderma bovis* larva (Cattle grubs) in cattle, ivermectin can induce serious adverse effects by killing the larva when they are in vital areas. Larva killed in the vertebral canal can cause paralysis and staggering. Larva killed around the gullet can induce salivation and bloat. These effects can be avoided by treating for grubs immediately after the Heal fly (Warble fly) season or after the stages of grub development where these areas would be affected. Cattle may experience discomfort or transient swelling at the injection site. Using a maximum of 10 mL at any one-injection site can help minimize these effects.

Neurotoxicity is possible in dogs, particularly in those with the gene defect (deletion mutation of the *mdr1* gene) that has been seen in certain genetic lines of Collie-type breeds.

In mice and rats, ivermectin may cause neurologic toxicity at doses slightly more than usually prescribed (less than 0.5 mg/kg).

In birds, death, lethargy or anorexia may be seen. Orange-cheeked Waxbill Finches and budgerigars may be more sensitive to ivermectin than other species.

For additional information refer to the Overdosage/Acute Toxicity section below.

Reproductive/Nursing Safety

Ivermectin is considered safe to use during pregnancy. Reproductive studies performed in dogs, horses, cattle and swine have not demonstrated adverse effects to fetuses. Reproductive performance in male animals is apparently unaltered. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: A (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Ivermectin is excreted in milk in low concentrations; it is unlikely to pose significant risk to nursing offspring.

Overdosage/Acute Toxicity

There were 660 exposures to ivermectin reported to the ASPCA Animal Poison Control Center (APCC) during 2005–2006. In these cases 575 were dogs with 104 showing clinical signs, 47 cats with 8 showing clinical signs, 9 wild felines with 3 showing clinical signs, 5 reported bird cases with 2 showing clinical signs, and 2 reported turtle cases with 1 showing clinical signs. The remaining 22 cases consisted of 12 rodents, 3 lagomorphs, 2 caprine, 2 equine, 1 ovine, and 2 unknown species none of which showed clinical signs. Common findings in dogs recorded in decreasing frequency included ataxia, blindness, mydriasis, tremors and vomiting. Common findings in cats recorded in decreasing frequency included ataxia, mydriasis, tremors, hyperesthesia and hypothermia. Common findings in wild felines recorded in decreasing frequency included ataxia, blindness and disorientation. Common findings in birds recorded in decreasing frequency included abasia, ataxia, head held low, lethargy and paresis. Common findings

in turtles in decreasing frequency included flaccid paralysis and unresponsiveness.

In dogs (non-sensitive breeds), signs of acute toxicity rarely occur at single dosages of 1 mg/kg (1000 microgram/kg) or less. At 2.5 mg/kg, mydriasis occurs, and at 5 mg/kg, tremors occur. At doses of 10 mg/kg, severe tremors and ataxia are seen. Deaths occurred when dosages exceeded 40 mg/kg, but the LD₅₀ is 80 mg/kg. Dogs (Beagles) receiving 0.5 mg/kg PO for 14 weeks developed no signs of toxicity, but at 1–2 mg/kg for the same time period, developed mydriasis and had some weight decreases. Half of the dogs receiving 2 mg/kg/day for 14 weeks developed signs of depression, tremors, ataxia, anorexia, and dehydration.

Ivermectin is actively transported by the p-glycoprotein pump and certain breeds susceptible to MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippets, etc.) are at higher risk for CNS toxicity. At the dosage recommended for heartworm prophylaxis, it is generally believed that the drug is safe to use in these animals.

Dogs who receive an overdosage of ivermectin or develop signs of acute toxicity (CNS effects, GI, cardiovascular) should receive supportive and symptomatic therapy. Emptying the gut should be considered for recent massive oral ingestions in dogs or cats. For both oral and injected ivermectin overdoses, the use of repeated activated charcoal doses is advised to interrupt enterohepatic recirculation.

Ivermectin has a large safety margin in cats. Kittens receiving doses of at least 110 mcg/kg and adult cats receiving at least 750 mcg/kg showed no untoward effects. Acute toxic signs associated with massive overdoses in cats will appear within 10 hours of ingestion. Signs may include agitation, vocalization, anorexia, mydriasis, rear limb paresis, tremors, and disorientation. Blindness, head pressing, wall climbing, absence of oculomotor menace reflex, and a slow and incomplete response to pupillary light may also be seen. Neurologic signs usually diminish over several days and most animals completely recover within 2–4 weeks. Symptomatic and supportive care is recommended.

In horses, doses of 1.8 mg/kg (9x recommended dose) PO did not produce signs of toxicity, but doses of 2 mg/kg caused signs of visual impairment, depression and ataxia.

In cattle, toxic effects generally do not appear until dosages of 30x those recommended are injected. At 8 mg/kg, cattle showed signs of ataxia, listlessness, and occasionally, death.

Sheep showed signs of ataxia and depression at ivermectin doses of 4 mg/kg.

Swine showed signs of toxicosis (lethargy, ataxia, tremors, lateral recumbency, and mydriasis) at doses of 30 mg/kg. Neonatal pigs may be more susceptible to ivermectin overdoses, presumably due to a more permeable blood-brain barrier. Accurate dosing practices are recommended.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ivermectin and may be of significance in veterinary patients:

■ **BENZODIAZEPINES:** Effects may be potentiated by ivermectin; use together not advised in humans

Caution is advised if using other drugs that can inhibit **p-glycoprotein**. Those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc., “white feet”) should probably not receive ivermectin with the following drugs, unless tested “normal”; drugs and drug classes involved include:

■ **AMIODARONE**

■ **CARVEDILOL**

- CLARITHROMYCIN
- CYCLOSPORINE
- DILTIAZEM
- ERYTHROMYCIN
- ITRACONAZOLE
- KETOCONAZOLE
- QUINIDINE
- SPIRONOLACTONE
- TAMOXIFEN
- VERAPAMIL

Laboratory Considerations

- When used at microfilaricide dosages, ivermectin may yield false-negative results in animals with occult heartworm infection.

Doses

■ DOGS:

Note: When used for prophylaxis or treatment of dirofilariasis it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information.

As a preventative for heartworm:

- a) 6–12 mcg/kg PO once monthly (Knight 2000)
- b) Minimum dosage of 6 micrograms/kg (0.006 mg/kg) PO per month. (Package insert; *Heartgard* 30[®]—MSD)

As a microfilaricide:

- a) When used to kill third, fourth, and young fifth stage larvae for prophylaxis or to kill these larval stages prior to adulticide therapy along with microfilariae, ivermectin is dosed at 6–12 mcg/kg PO once a month. When only used to kill circulating microfilariae, ivermectin can be administered at 6 mcg/kg (the approved prophylactic dose) or at a dose of 50 mcg/kg (approximately 10 times the prophylactic dose). Microfilariae numbers decrease gradually to, or close to, zero within several months at the lower dose. The chance of adverse reactions with this approach is minimal. The higher dose results in a rapid kill that is associated with more adverse effects. (Kittleson 2006b)

As an ectoparasiticide (miticide):

- a) For generalized demodicosis: **Note:** Do not consider use in MDR1 mutation susceptible breeds unless tested “normal/normal” for mutation www.vetmed.wsu.edu. If normal/normal, drug reaction is very unlikely. Start at low dosage and increase:

Day 1: 100 mcg/kg PO q24h,

Day 4: 200 mcg/kg PO q24h,

Day 7: 300 mcg/kg; continue to increase by 100 mcg/kg every 3rd day until reach target dose of 600 mcg/kg PO daily and continue treatment 1–2 months after 2 negative skin scrapes. Treatment usually requires 10–33 weeks. (Hillier 2006g)

- b) For demodicosis: 400–600 mcg/kg PO daily. Consider using the test dose method: Start at 100 mcg/kg PO and increase by 100 mcg/day until target dose is reached. Treatment typically required for 2–4 months. If toxicity is noted, discontinue. Do not use in collies, Shelties, Old English Sheepdogs and other herding dogs. (DeManuelle 2000)
- c) As scabicide: 300–400 mcg/kg PO or SC once weekly for weeks. If using the 1% injection, 1 mL = 10,000 mcg. Beware in sensitive breeds (e.g., Collies, etc.; “white feet, don’t treat”). Check heartworm status prior to treatment. Adverse effects are rare outside of sensitive breeds. (Foil 2003c)

As an endoparasiticide:

- a) For treatment of parasitic lung disease (*Capillaria* spp.): 0.2 mg/kg PO once (Bauer 1988)
- b) For *Oslerus osleri*: 0.4 mg/kg SC once (Reinemeyer 1995)
- c) For *Eucoleus boehmi*: 0.2 mg/kg PO once (Reinemeyer 1995)
- d) For *Pneumonyssoides caninum*: 0.2 mg/kg SC once (Reinemeyer 1995)

■ CATS:

Note: When used for prophylaxis or treatment of dirofilariasis it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information

As a preventative for heartworm:

- a) Minimum effective dosage: 0.024 mg/kg (24 micrograms/kg) PO every 30–45 days (**Note:** also controls hookworms at this dosage) (Knight 1995)

For *Aelurostrongylus abstrusus*:

- a) 0.4 mg/kg SC once (Reinemeyer 1995); (Hawkins 2000)

■ FERRETS:

For prevention of heartworm disease:

- a) 0.02 mg/kg PO monthly (Hoeffler 2000)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: For *Sarcoptes scabiei*, *Notoedres cati*: 0.3–0.4 mg/kg SC, repeat in 14 days.

For ear mites (*Psoroptes*) 0.2–0.44 mg/kg PO, SC repeat in 8–18 days (Ivey and Morrissey 2000)

- b) Rabbits: For treatment of ear mites: 200 mcg/kg SC and repeated in two weeks. All rabbits in colony should be treated and cages cleaned and disinfected. (Burke 1999)
- c) Rodents and lagomorphs: For treatment of sarcoptoid and some fur mites: 200–250 mcg/kg SC. Cages should be thoroughly cleaned and disinfected. (Burke 1999)
- d) Mice, Rats, Gerbils, Guinea pigs, Chinchillas: 200 mcg/kg SC or PO every 7 days for 3 weeks Hamsters: 200–500 mcg/kg SC or PO every 14 days for 3 weeks (Adamcak and Otten 2000)
- e) Guinea pigs for *Trixacarus caviae* mites: 500 mcg/kg SC, repeated at 14 and 28 days. (Johnson 2006d)

■ CATTLE:

For susceptible parasites:

- a) 200 micrograms/kg SC. Doses greater than 10 mL should be given at two separate sites. (Paul 1986)
- b) For psoroptic mange: 200 mg/kg IM (**Note:** Reference was written before approval of the SC labeled bovine product); isolate from other cattle for at least 5 days after treatment. (Mullowney 1986)
- c) 200 micrograms/kg (0.2 mg/kg) SC under the loose skin in front of or behind the shoulder (Product Information; *Ivomec*® Inj. for Cattle 1%—MSD)

■ HORSES:

For susceptible parasites:

- a) 200 micrograms/kg (0.2 mg/kg) PO using oral paste or oral liquid (Product Information; *Eqvalan*®—MSD)
- b) 0.2 mg/kg PO; 0.2 mg/kg PO at 4 day intervals for lice and mange (Robinson 1987)
- c) As a larvicide for arterial stages of *S. vulgaris*: 0.2 mg/kg once (Herd 1987)

■ SWINE:

For susceptible parasites:

- a) 300 micrograms/kg (0.3 mg/kg) SC in the neck immediately behind the ear (Product Information; *Ivomec*® Inj. for Swine 1%—MSD)

- b) For general control of endo- and ectoparasites in potbellied pigs: 300 micrograms/kg SC or IM once for internal parasites and repeated in 10–14 days for external parasites (only partially effective against whipworms—see fenbendazole) (Braun 1995)

■ SHEEP:

For susceptible parasites:

- 200 micrograms/kg for nasal bot infection (Bennett 1986)
- 200 micrograms/kg SC for one dose (goats also) (Upson 1988)

■ LLAMAS:

For susceptible parasites:

- 0.2 mg/kg PO or SC for one dose (Cheney and Allen 1989), (Fowler 1989)

■ BIRDS:

For susceptible parasites:

- For ascarids, Capillaria and other intestinal worms, *Knemidocoptes pilae* (scaly face and leg mites): Dilute to a 2 mg/mL concentration. After diluting product, use immediately.

Most birds: Inject 220 mcg/kg IM;

Parakeets: 0.02 mg/30 g (2000 mcg/30 gram) IM;

Amazons: 0.1 mg IM;

Macaws: 0.2 mg IM;

Finches: 0.02 mg (Stunkard 1984)

- For ascarids, coccidia and other intestinal nematodes, *Oxyuris equi*, gapeworms, *Knemidocoptes pilae* (scaly face and leg mites): Dilute bovine preparation (10 mg/mL) 1:4 with propylene glycol.

For most species: 200 mcg/kg IM or orally; repeat in 10–14 days.

Budgerigars: 0.01 mL of diluted product (see above) IM or PO (Clubb 1986)

- 200 mcg/kg (0.2 mg/kg) SC; dilute using propylene glycol. (Sikarskie 1986)

- Ratites: 200 mcg/kg PO, IM or SC. Has efficacy against *Chandlerella quiscalis* in emus. (Jenson 1998)

■ REPTILES:

For most nematodes, ectoparasites:

- For lizards, snakes, and alligators: 0.2 mg/kg (200 mcg/kg) IM, SC, or PO once; repeat in 2 weeks **Note:** Ivermectin is toxic to chelonians (Gauvin 1993)

Monitoring

■ Clinical efficacy

■ Adverse effects/toxicity (see Adverse Effects and Overdosage Sections)

Client Information

- When using large animal products the manufacturer recommends not eating or smoking and to wash hands after use. Avoid contact with eyes.

- Dispose of unused products and containers by incineration or in approved-landfills. Ivermectin may adversely affect fish or other water-borne organisms if disposed in water.

- Contact veterinarian if any treated animal exhibits signs of toxicity (see Adverse effects and Overdosage sections above).

Chemistry/Synonyms

An avermectin anthelmintic, ivermectin occurs as an off-white to yellowish powder. It is very poorly soluble in water (4 micrograms/mL), but is soluble in propylene glycol, polyethylene glycol, and vegetable oils.

Ivermectin may also be known as MK 933, Ivermectine, Ivermectinum or Ivermectina; many trade names are available.

Storage/Stability/Compatibility

Ivermectin is photolabile in solution; protect from light. Unless otherwise specified by the manufacturer, store ivermectin products at room temperature (15–30°C).

Ivermectin 1% oral solution (equine tube wormer product) is stable at 1:20 and 1:40 dilutions with water for 72 hours when stored in a tight container, at room temperature, and protected from light.

Dosage Forms/Regulatory Status

VETERINARY APPROVED PRODUCTS:

Note: As ivermectin is no longer patent protected in the USA, there are a variety of “generic” products available with many trade names. The following may not be a complete listing.

Ivermectin for Injection: 10 mg/mL (1%) in 50 mL, 200 mL and 500 mL packs; *Ivomec*® (Merial); (OTC); Approved for use in swine. Slaughter withdrawal (at labeled doses) = 18 days.

Ivermectin for Injection: 10 mg/mL (1%) and Clorsulon 100 mg/mL; *Ivomec*® Plus Injection for Cattle (Merial); (OTC). Approved for use in cattle (not female dairy cattle of breeding age). Slaughter withdrawal (at labeled doses) = 40 days. No milk withdrawal has been established.

Ivermectin for Injection: 10 mg/mL (1%) in 50 mL, 200 mL, 500 mL bottles; *Ivomec*® 1% Injection for Cattle and Swine (Merial), *Double Impact*® (AgriLabs); *Ultramectrin*® Injection (RXV); (OTC). Approved for use in cattle (not female dairy cattle of breeding age) and swine. Slaughter (when used as labeled): cattle = 35 days, swine = 18 days, reindeer = 56 days, bison = 56 days. No milk withdrawal time has been established.

Ivermectin for Injection: 2.7 mg/mL (0.27%) in 200 mL bottles; *Ivomec*® 0.27% Injection for Feeder and Grower Pigs (Merial); (OTC). Approved for use in swine. Slaughter (when used as labeled) = 18 days

Ivermectin Oral Paste: 1.87% (18.7 mg/gram) in 6.08 g syringes; *Equimectrin*® Paste 1.87% (Farnam), *Eqvalan*® Paste 1.87% (Merial), *Rotectin*® 1 Paste 1.87% (Farnam), *Zimectrin*® Paste (Farnam); (OTC). Approved for use in horses (not intended for food purposes).

Oral Paste: containing 1.87% ivermectin and 14.03% of praziquantel in oral syringes (sufficient to treat one 1320 lb horse); *Equimax*® (Pfizer); (OTC). Approved for use in horse or ponies not intended for food purposes.

Oral Paste: containing 1.55% ivermectin and 7.75% of praziquantel in oral syringes; *Zimecterin Gold*® (Merial); (OTC). Approved for use in horse or ponies not intended for food purposes.

Ivermectin Liquid: 1% (10 mg/mL) in 50 mL and 100 mL btlts (for tube administration; **NOT** for injection); *Amtech Phoenectin*® Liquid for Horses (Phoenix Scientific), *Eqvalan*® Liquid (Merial), *Ivercide*® Liquid for Horses (Phoenix Pharmaceutical); (Rx). Approved for use in horses (not intended for food purposes).

Ivermectin Oral Tablets: 68 mcg, 136 mcg, 272 mcg (Plain or Chewable) in 6 chewables in carton in 10 carton trays, *Heartgard*® Tablets (Merial), *Heartgard*® Chewables (Merial); (Rx). Approved for use in dogs.

Ivermectin Oral Chewable Tablets: 55 mcg or 165 mcg in cartons of 6 in 10 cartons per tray. *Heartgard*® for Cats (Merial); (Rx) Approved for use in cats.

Ivermectin/Pyrantel Oral Tablets: 68 mcg/57 mg, 136 mcg/114mg, 272 mcg/228 mg; *Heartgard*® Plus Chewables (Merial); *Tri-Heart*® Plus Chewable Tablets (Schering); (Rx). Approved for use in dogs.

Ivermectin Oral Solution: 0.08% in 960 mL and 4,800 mL containers; *Ivomec® Sheep Drench* (Merial); (OTC); Approved for use in sheep. Slaughter withdrawal time = 11 days.

Ivermectin Bolus: 1.72 g; *Ivomec® SR Bolus* (Merial); (OTC). Approved for use in cattle (not female dairy cattle of breeding age). Slaughter withdrawal time = 180 days. No milk withdrawal time has been established.

Ivermectin Medicated feeds: *Ivomec® Premix for Swine Type A Medicated Article* (Merial) 0.6% in 50 lb. *Ivomec® Premix for Swine Type C Medicated Feed 0.02%* (Merial) in 20 lb one-ton bag and 40 lb two-ton bag, *Ivomec® Premix for Swine Type C medicated feed 0.1%* (Merial) in 20 lb one-ton bag. Approved for use in swine. Slaughter withdrawal = 5 days

Ivermectin Topical Parasiticide Pour-on for Cattle: 5 mg/mL 250 mL, 500 mL, 1 liter and 1 gallon bottles. Approved for use in cattle (not female dairy cattle of breeding age). Slaughter withdrawal time = 48 days, milk withdrawal has not been established. *Amtech Phoenectin® Pour-on for Cattle* (Phoenix Scientific), *Bimectin® Pour-On* (Bimeda), *Ivercide® Pour-On for Cattle* (Phoenix Pharmaceutical), *Ivermectin® Pour-On* (Aspen, Durvet), *Ivomec® Eprinex® Pour-on for Beef and Dairy Cattle* and *Ivomec® Pour-on for Cattle* (Merial), *Prozap® Ivermectin Pour-on* (Loveland), *Top Line®* (AgriLabs), *Ultramectrin® Pour-On* (RXV); (OTC)

An otic product *Acarexx®* is also available.

HUMAN-LABELED PRODUCTS:

Ivermectin Tablets: 3 mg and 6 mg; *Stromectol®* (Merck); (Rx)

KAOLIN/PECTIN

(kay-oh-lin/pek-tin) Kaopectolin

GI ADSORBENT/PROTECTANT

Prescriber Highlights

- ▶ Adsorbent for treatment of diarrhea & GI toxins; questionable efficacy
- ▶ Contraindications: Should not be relied on to control severe diarrheas or to replace adequate fluid/electrolyte monitoring or as replacement therapy in severe or chronic diarrheas
- ▶ Adverse Effects: Transient constipation
- ▶ Drug Interactions

Uses/Indications

Although its efficacy is in question, kaolin/pectin is used primarily in veterinary medicine as an oral anti-diarrheal agent. It has also been used as an adsorbent agent following the ingestion of certain toxins. Administration may be difficult due to the large volumes that may be necessary to give orally.

Pharmacology/Actions

Kaolin/pectin is thought to possess adsorbent and protective qualities. Presumably, bacteria and toxins are adsorbed in the gut and the coating action of the suspension may protect inflamed GI mucosa. The pectin component, by forming galacturonic acid, has been demonstrated to decrease pH in the intestinal lumen.

In one study in children with acute nonspecific diarrhea, stool fluidity was decreased, but stool frequency, water content, and weight remained unchanged. No studies documenting the clinical

efficacy of this combination in either human or veterinary species were located.

Pharmacokinetics

Neither kaolin nor pectin are absorbed after oral administration. Up to 90% of the pectin administered may be decomposed in the gut.

Contraindications/Precautions/Warnings

There are no absolute contraindications to kaolin/pectin therapy, but it should not be relied on to control severe diarrheas. Kaolin/pectin should not replace adequate fluid/electrolyte monitoring or replacement therapy in severe or chronic diarrheas.

Adverse Effects

At usual doses, kaolin/pectin generally has no adverse effects. Constipation may occur, but is usually transient and associated with high dosages. High doses in debilitated, or in very old or young patients may rarely cause fecal impaction. In rats, kaolin/pectin has been demonstrated to increase fecal sodium loss in diarrhea.

In humans, kaolin/pectin is recommended for use only under the direct supervision of a physician, in patients less than 3 years of age or for longer than 48 hours.

Reproductive/Nursing Safety

Adsorbent (only) anti-diarrheal products should be safe to use during pregnancy and lactation. The addition of other active ingredients (e.g., as opiates) may alter this recommendation.

Overdosage/Acute Toxicity

Overdosage is unlikely to cause any serious effects, but constipation requiring treatment may occur.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving kaolin/pectin and may be of significance in veterinary patients:

- **DIGOXIN:** Some evidence exists that kaolin/pectin may impair the oral absorption of digoxin. Separate doses by at least two hours.
- **LINCOMYCIN:** Kaolin/pectin may inhibit the oral absorption of lincomycin. If both drugs are to be used, administer kaolin/pectin at least 2 hours before or 3–4 hours after the lincomycin dose.

Doses

■ DOGS:

For diarrhea:

- a) 1–2 mL/kg PO q4–6h (Davis 1985a)
- b) 1–2 mL/kg PO four times daily (Johnson 1984)
- c) 1–2 mL/kg PO q2–6h (Kirk 1986)

For enterotoxins secondary to garbage ingestion:

- a) 2–5 mL/kg PO q1–6 hours (Coppock and Mostrom 1986)
- b) 10–15 grams of kaolin/kg PO four times daily (Grauer and Hjelle 1988a)

■ CATS:

For diarrhea:

- a) 1–2 mL/kg PO q4–6h (Davis 1985a)
- b) 1–2 mL/kg PO four times daily (Johnson 1984)
- c) 1–2 mL/kg PO q2–6h (Kirk 1986)

■ FERRETS:

- a) 1–2 mL/kg PO 3–4 times daily (Williams 2000)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Guinea pigs: 0.2 mL PO 3–4 times a day (Adamcak and Otten 2000)

■ CATTLE:

- a) Adult: 4–10 fl. oz. PO; Calves: 2–3 fl. oz PO; repeat every 2–4 hours or as indicated until condition improves. If no improvement in 48 hours additional treatment is indicated. (Label Directions; *Kao-Forte*®—Vet-A-Mix)

■ HORSES:

For diarrhea:

- a) 2–4 quarts PO per 450 kg body weight twice daily (Robinson 1987)
- b) 1 oz. per 8 kg body weight PO 3–4 times a day (Clark and Becht 1987)
- c) Foals: 3–4 oz PO q6–8h (authors believe that bismuth subsalicylate is superior) (Martens and Scrutchfield 1982)

■ SWINE:

- a) ½–2 fl. oz PO; repeat every 2–4 hours or as indicated until condition improves. If no improvement in 48 hours additional treatment is indicated. (Label Directions; *Kao-Forte*®—Vet-A-Mix)

■ SHEEP:

- a) 3–4 oz PO q2–3h (McConnell and Hughey 1987)

■ BIRDS:

- a) Canary or parakeet: 1 drop PO twice daily; or 1 and ½ drop-perful placed in 2/3 oz. drinking water.
Medium-sized birds: 0.5 mL PO
Large birds: 1 mL PO 1 to 4 times a day (Stunkard 1984)
- b) 2 mL/kg PO two to four times a day (Clubb 1986)

Monitoring

- Clinical efficacy
- Fluid and electrolyte status in severe diarrhea

Client Information

- Shake well before using
- If diarrhea persists, or if animal appears listless or develops a high fever, contact veterinarian

Chemistry/Synonyms

Kaolin is a naturally occurring hydrated aluminum silicate that is powdered and refined for pharmaceutical use. Kaolin is a white/light, odorless, almost tasteless powder that is practically insoluble in water.

Pectin is a carbohydrate polymer consisting primarily of partially methoxylated polygalacturonic acids. Pectin is a coarse or fine, yellowish-white, almost odorless with a mucilaginous flavor. It is obtained from the inner rind of citrus fruits or from apple pomace. One gram of pectin is soluble in 20 mL of water and forms a viscous, colloidal solution.

In the United States, the two compounds generally are used together in an oral suspension formulation in most proprietary products.

Kaolin may also be known as: bolus alba, E559, weisser ton, *Childrens Diarrhoea Mixture*®, *Entrocalm*®, *Kao-Pec*®, *Kao-Pect*®, *Kao-Pront*®, *Kaogel*®; many multi-ingredient trade names are available.

Storage/Stability/Compatibility

Kaolin/pectin should be stored in airtight containers; protect from freezing. It is physically **incompatible** when mixed with alkalis, heavy metals, salicylic acid, tannic acid, or strong alcohol.

Dosage Forms/Regulatory Status

There are variety of kaolin/pectin products available without prescription. Several products are labeled for veterinary use; their approval status is not known. Many products that formerly contained kaolin (e.g., *Kaopectate*®) no longer contain any kaolin, but use attapulgite as the adsorbent.

VETERINARY-LABELED PRODUCTS:

Kaolin Pectin 90 gr kaolin/2 g pectin per fluid oz. in 1 quart and 1 gallon containers. generic, (Bimeda, Durvet), *Kaolin Pectin Plus*® (AgriPharm), *Kao-Pec*® (AgriLabs), *Kao-Pect*® (Phoenix Pharmaceutical), *Kaopectolin* (Aspen, Butler); (OTC). Products may be labeled for use in horses, cattle, dogs and cats.

Kaolin Pectin 90 gr kaolin/4 g pectin per fl oz. in 1 gallon containers. *Kaolin Pectin Suspension* (Vedco); (OTC)

HUMAN-LABELED PRODUCTS:

Kaolin, Pectin Antidiarrheal Suspension: 90 g kaolin, 2 g pectin/30 mL in 180 mL and 360 mL, pt and UD 30 mL; *Kaopectolin* (various); generic; (OTC)

KETAMINE HCL

(kee-ta-meen) Ketaset®, Ketaflo®, Vetalar®

DISSOCIATIVE GENERAL ANESTHETIC;
NMDA-RECEPTOR ANTAGONIST

Prescriber Highlights

- Dissociative general anesthetic; also inhibits NMDA-receptors so may be adjunctively useful to control pain
- Contraindications: Prior hypersensitivity reactions; animals to be used for human consumption, alone for general anesthesia, increased CSF pressure/head trauma
- Relative contraindications: Significant blood loss, malignant hyperthermia, increased intra-ocular pressure or open globe injuries; procedures involving the pharynx, larynx, or trachea
- Caution: Significant hypertension, heart failure, & arterial aneurysms, hepatic or renal insufficiency, seizure disorders
- Adverse Effects: Hypertension, hypersalivation, respiratory depression, hyperthermia, emesis, vocalization, erratic & prolonged recovery, dyspnea, spastic jerking movements, seizures, muscular tremors, hypertonicity, opisthotonos, & cardiac arrest; pain after IM injection may occur
- Cats' eyes remain open after ketamine; protect
- Minimize exposure to handling or loud noises during the recovery period, but monitor adequately
- Drug interactions

Uses/Indications

Ketamine has been approved for use in humans, sub-human primates, and cats, although it has been used in many other species (see Dosage section). The approved indications for cats include, "for restraint, or as the sole anesthetic agent for diagnostic, or minor, brief, surgical procedures that do not require skeletal muscle relaxation... and in subhuman primates for restraint." (Package Insert; *Ketaset*®—Bristol).

Ketamine can inhibit NMDA receptors in the CNS and can decrease “wind-up” effect. There is increasing interest in using it to prevent exaggerated pain associated with surgery or chronic pain states in animals.

Pharmacology/Actions

Ketamine is a rapid acting general anesthetic that has significant analgesic activity and a lack of cardiopulmonary depressant effects. It is thought to induce both anesthesia and amnesia by functionally disrupting the CNS through over stimulating the CNS or inducing a cataleptic state. Ketamine inhibits GABA, and may block serotonin, norepinephrine, and dopamine in the CNS. The thalamo-neocortical system is depressed while the limbic system is activated. It induces anesthetic stages I and II, but not stage III. In cats, it causes a slight hypothermic effect as body temperatures decrease on average by 1.6°C after therapeutic doses.

Effects on muscle tone are described as being variable, but ketamine generally either causes no changes in muscle tone or increased tone. Ketamine does not abrogate the pinnal and pedal reflexes, nor the photic, corneal, laryngeal or pharyngeal reflexes.

Ketamine's effects on the cardiovascular system include increased cardiac output, heart rate, mean aortic pressure, pulmonary artery pressure, and central venous pressure. Its effects on total peripheral resistance are described as being variable. Cardiovascular effects are secondary to increased sympathetic tone; ketamine has negative inotropic effects if the sympathetic system is blocked.

Ketamine does not cause significant respiratory depression at usual doses, but at higher doses it can cause respiratory rates to decrease. In humans with asthma, ketamine causes decreased airway resistance.

Pharmacokinetics

After IM injection in the cat, peak levels occur in approximately 10 minutes. Ketamine is distributed into all body tissues rapidly, with highest levels found in the brain, liver, lung, and fat. Plasma protein binding is approximately 50% in the horse, 53% in the dogs, and 37–53% in the cat.

The drug is metabolized in the liver principally by demethylation and hydroxylation and these metabolites, along with unchanged ketamine, are eliminated in the urine. Ketamine will induce hepatic microsomal enzymes, but there appears to be little clinical significance associated with this effect. The elimination half-life in the cat, calf, and horse is approximately 1 hour, in humans it is 2–3 hours. Like the thiobarbiturates, the redistribution of ketamine out of the CNS is more of a factor in determining duration of anesthesia than is the elimination half-life.

By increasing the dose, the duration of anesthesia will increase, but not the intensity.

Contraindications/Precautions/Warnings

Ketamine is contraindicated in patients who have exhibited prior hypersensitivity reactions to it and animals to be used for human consumption. Use in patients with significant hypertension, heart failure, and arterial aneurysms could be hazardous. The manufacturer warns against its use in patients with hepatic or renal insufficiency but in humans with renal insufficiency, the duration of action is not prolonged. Because ketamine does not provide good muscle relaxation, it is contraindicated when used alone for major surgery.

Ketamine can cause increases in CSF pressure and it should not be used in cases with elevated pressures or when head trauma has occurred. Because of its supposed epileptogenic potential, it should generally not be used (unless very cautiously) in animals with preexisting seizure disorders. As myelography can induce sei-

zures, ketamine should be used cautiously in animals undergoing this procedure.

Ketamine is considered to be relatively contraindicated when increased intra-ocular pressure or open globe injuries exist, and for procedures involving the pharynx, larynx, or trachea. Animals that have lost significant amounts of blood, may require significantly reduced ketamine dosages.

While ketamine has been used safely in humans with malignant hyperthermia, its use in animals susceptible to this condition is controversial. Hyperthyroid human patients (and those receiving exogenous thyroid replacement) may be susceptible to developing severe hypertension and tachycardia when given ketamine. The veterinary significance of this potential problem is unknown.

Cats' eyes remain open after receiving ketamine, and should be protected from injury plus an ophthalmic lubricant (e.g., *Lacri-Lube*®) should be applied to prevent excessive drying of the cornea.

To minimize the incidences of emergence reactions, it is recommended to minimize exposure to handling or loud noises during the recovery period. The monitoring of vital signs should still be performed during the recovery phase, however.

Because ketamine can increase blood pressure, careful control of post-surgical hemorrhage (e.g., declawing) should be managed. It is not essential to withhold food or water prior to surgery, but in elective procedures, it is recommended to withhold food for 6 hours prior to surgery.

Adverse Effects

In approved species the following adverse reactions are listed by the manufacturer: “respiratory depression . . . following high doses, emesis, vocalization, erratic and prolonged recovery, dyspnea, spastic jerking movements, convulsions, muscular tremors, hypertonicity, opisthotonos and cardiac arrest. In the cat, myoclonic jerking and/or tonic/clonic convulsions can be controlled by ultrashort-acting barbiturates or acepromazine. These latter drugs must be given intravenously, cautiously, and slowly, to effect (approximately 1/6 to 1/4 the normal dose may be required).” (Package Insert; *Ketaset*®—Fort Dodge)

Seizures have been reported to occur in up to 20% of cats that receive ketamine at therapeutic dosages. Diazepam is suggested if treatment is necessary. It has been reported to rarely cause a variety of other CNS effects (mild CNS effects to blindness and death). Ketamine has been documented to cause hyperthermia in cats; low doses of acepromazine (0.01–0.02 mg/kg IV) may alleviate. Anecdotal reports of ketamine causing acute, CHF in cats with mild to moderate heart disease have been reported.

Pain after IM injection may occur.

To reduce the incidence of hypersalivation and other autonomic signs, atropine or glycopyrrolate is often administered.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

No specific lactation information was found.

Overdosage/Acute Toxicity

Ketamine is considered to have a wide therapeutic index (approximately 5 times greater when compared to pentobarbital). When given too rapidly or in excessive doses, significant respiratory depression may occur. Treatment using mechanically assisted respiratory support is recommended versus the use of analeptic agents. In cats, yohimbine with 4-aminopyridine has been suggested for use as a partial antagonist.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ketamine and may be of significance in veterinary patients:

- **CHLORAMPHENICOL (parenteral):** May prolong the anesthetic actions of ketamine
- **CNS DEPRESSANTS:** Narcotics, barbiturates, or diazepam may prolong the recovery time after ketamine anesthesia
- **HALOTHANE:** When used with halothane, ketamine recovery rates may be prolonged and the cardiac stimulatory effects of ketamine may be inhibited; close monitoring of cardiac status is recommended when using ketamine with halothane
- **NEUROMUSCULAR BLOCKERS** (e.g., **succinylcholine** and **tubocurarine**): May cause enhanced or prolonged respiratory depression
- **THYROID HORMONES:** When given concomitantly with ketamine, thyroid hormones have induced hypertension and tachycardia in humans; beta-blockers (e.g., propranolol) may be of benefit in treating these effects

Doses

Note: Ketamine is used in many different combinations with other agents. The following are representative, but not necessarily inclusive; it is suggested to refer to a recent veterinary anesthesia reference for more information.

■ DOGS:

Note: Ketamine/xylazine has induced cardiac arrhythmias, pulmonary edema, and respiratory depression in dogs. This combination should be used with caution.

As an adjunct to anesthesia:

- a) Diazepam 0.5 mg/kg IV, then ketamine 10 mg/kg IV to induce general anesthesia (Booth 1988a)
- b) Midazolam 0.066–0.22 mg/kg IM or IV, then ketamine 6.6–11 mg/kg IM (Mandsager 1988)
- c) Xylazine 2.2 mg/kg IM, in 10 minutes give ketamine 11 mg/kg IM. Dogs weighing more than 22.7 kg (50 lbs.) reduce dose (per kg) of both drugs by approx. 25% (Booth 1988a)
- d) Atropine (0.044 mg/kg) IM, in 15 minutes give xylazine (1.1 mg/kg) IM, 5 minutes later give ketamine (22 mg/kg) IM (Booth 1988a)

As an NMDA antagonist for adjunctive pain control:

- a) 0.1–1 mg/kg PO, IM or SC q4–6h for mild to moderate pain in conjunction with opioids. (Nieves 2002)
- b) For intraoperative use: If anesthesia was induced with a drug other than ketamine, give a loading dose of 0.5 mg/kg IV, then an infusion of 10–20 mcg/kg/minute. A CRI of 2–10 mcg/kg/minute can be used post-op. (Hellyer 2006)

■ CATS:

Most clinicians recommend giving atropine or glycopyrrolate before use to decrease hypersalivation.

- a) 11 mg/kg IM for restraint; 22–33 mg/kg for diagnostic or minor surgical procedures not requiring skeletal muscle relaxation (Package Insert; *Ketaset*®—Bristol)
- b) 2–4 mg/kg IV or 11–33 mg/kg IM (Davis 1985b)

- c) Restraint: 0.1 mL (10 mg) IV
Anesthesia: 22–33 mg/kg IM or 2.2–4.4 mg/kg IV (with atropine) (Morgan 1988)
- d) Sedation, restraint: 6.6–11 mg/kg IM
Anesthetic: 17.6–26.4 mg/kg IM
Induction (following sedation): 4.4–11 mg/kg IV (Mandsager 1988)

As an NMDA antagonist for adjunctive pain control:

- a) 0.1–1 mg/kg IM or SC q4–6h for mild to moderate pain in conjunction with opioids. (Nieves 2002)
- b) For intraoperative use: If anesthesia was induced with a drug other than ketamine, give a loading dose of 0.5 mg/kg IV, then an infusion of 10–20 mcg/kg/minute. A CRI of 2–10 mcg/kg/minute can be used post-op. (Hellyer 2006)

■ RABBITS/RODENTS/SMALL MAMMALS:

For chemical restraint:

- a) Mice: Alone: 50–100 mg/kg IM or IP, 50 mg/kg IV;
In combination with diazepam: Ketamine 200 mg/kg with Diazepam 5 mg/kg IM or IP;
In combination with xylazine: Ketamine 100 mg/kg with Xylazine 5–15 mg/kg IM or IP (Burke 1999)
- b) Rats: Alone: 50–100 mg/kg IM or IP, 40–50 mg/kg IV;
In combination with diazepam: Ketamine 40–60 mg/kg/Diazepam 5–10 mg/kg IP;
In combination with xylazine: Ketamine 40–75 mg/kg with Xylazine 5–12 mg/kg IM or IP (Burke 1999)
- c) Hamsters/Gerbils: 100 mg/kg IM;
In combination with diazepam: Ketamine 50 mg/kg with Diazepam 5 mg/kg IM;
In combination with xylazine: Not recommended (Burke 1999)
- d) Guinea pig: Alone: 10–30 mg/kg IM;
In combination with diazepam: Ketamine 60–100 mg/kg with Diazepam 5–8 mg/kg IM;
In combination with xylazine: Ketamine 85 mg/kg with Xylazine 12–13 mg/kg IM (Burke 1999)
- e) Rabbits: Alone: 20–60 mg/kg IM or IV;
In combination with diazepam: Ketamine 60–80 mg/kg with Diazepam 5–10 mg/kg IM;
In combination with xylazine: Ketamine 10 mg/kg with Xylazine 3 mg/kg IV (Burke 1999)
- f) Rabbits: Alone: 20–50 mg/kg IM or 15–20 mg/kg IV
In combination with diazepam for induction: Diazepam 5–10 mg/kg IM give ketamine 30 minutes after diazepam at 20–40 mg/kg IM or Diazepam 0.2–0.5 mg/kg and Ketamine 10–15 mg/kg (to effect) IV;
In combination with diazepam for anesthesia without inhalants: Diazepam 5–10 mg/kg IM plus ketamine 60–80 mg/kg IM 30 minutes later;
In combination with xylazine: Not recommended for pet rabbits (Ivey and Morrissey 2000)

■ FERRETS:

- a) For injectable anesthesia: Butorphanol 0.1 mg/kg, Ketamine 5 mg/kg, medetomidine 80 mcg/kg. Combine in one syringe and give IM. May need to supplement with isoflurane (0.5–1.5%) for abdominal surgery. (Finkler 1999)

■ CATTLE:

- a) Premedicate with atropine and xylazine, then ketamine 2 mg/kg IV bolus (Thurmon and Benson 1986)
- b) After sedation, 2.2 mg/kg IV (Mandsager 1988)

■ HORSES: (Note: ARCI UCGFS Class 2 Drug)

- For field anesthesia: Sedate with xylazine (1 mg/kg IV; 2 mg/kg IM) given 5–10 minutes (longer for IM route) before induction of anesthesia with ketamine (2 mg/kg IV). Horse must be adequately sedated (head to the knees) before giving the ketamine (ketamine can cause muscle rigidity and seizures). If adequate sedation does not occur, either: **1**) Redose xylazine: up to half the original dose, or **2**) Add butorphanol (0.02–0.04 mg/kg IV). Butorphanol can be given with the original xylazine if you suspect that the horse will be difficult to tranquilize (e.g., high-strung Thoroughbreds) or added before the ketamine. This combination will improve induction, increase analgesia and increase recumbency time by about 5–10 minutes, or **3**) Diazepam (0.03 mg/kg IV). Mix the diazepam with the ketamine. This combination will improve induction when sedation is marginal, improve muscle relaxation during anesthesia and prolong anesthesia by about 5–10 minutes, or **4**) Guaifenesin (5% solution administered IV to effect) can also be used to increase sedation and muscle relaxation. (Mathews 1999)
- Initially give xylazine 1.1 mg/kg IV and wait for full sedative effect (4–8 minutes); then give ketamine 2.2–2.75 mg/kg IV only (the higher dose may be necessary for ponies, young “high-strung” Arabians, Hackneys, and Thoroughbreds) as a bolus. Do not administer to an “excited” horse. If surgery time requires additional anesthesia, $\frac{1}{3}$ – $\frac{1}{2}$ of the original xylazine/ketamine doses may be given IV. For procedures where better muscle relaxation is required, use guaifenesin-thiobarbiturate. Do not disturb horse until fully recovered. (Thurmon and Benson 1987)
- For foals and ponies: Add 500 mg ketamine and 250 mg xylazine to 500 mL of 5% guaifenesin solution. For induction, give 1.1 mL/kg IV rapidly. Anesthesia may be maintained by constant IV infusion of 2–3 mL/kg/hr. Lower doses for foals, higher doses for ponies. (Thurmon and Benson 1987)
- For induction of surgical colic patients: Use guaifenesin to effect, then 1.6–2.2 mg/kg ketamine (Mandsager 1988)
- 200 mg bolus (in a 454 kg horse) intra-operatively to reduce movement with light general anesthesia (Mandsager 1988)

■ SWINE:

- Give atropine, then ketamine at 11 mg/kg IM. To prolong anesthesia and increase analgesia give additional ketamine 2–4 mg/kg IV. Local anesthetics injected at the surgical site (e.g., 2% lidocaine) may enhance analgesia. (Thurmon and Benson 1986)
- Ketamine (22 mg/kg) combined with acepromazine (1.1 mg/kg) IM (Swindle 1985)
- 4.4 mg/kg IM or IV after sedation (Mandsager 1988)

■ SHEEP:

- Premedicate with atropine (0.22 mg/kg) and acepromazine (0.55 mg/kg; then ketamine 22 mg/kg IM. To extend anesthetic time, may give ketamine intermittently IV at 2–4 mg/kg. (Thurmon and Benson 1986)
- 2 mg/kg IV for induction, then 4 mL/minute constant infusion of ketamine in a concentration of 2 mg/mL in D5W (Thurmon and Benson 1986)

■ GOATS:

- Give atropine 0.4 mg/kg, followed by xylazine 0.22 mg/kg IM 20–25 minutes later. Approximately 10 minutes after xylazine give ketamine 11 mg/kg IM. To extend anesthesia give ketamine 2–4 mg/kg IV (shorter extension) or 6 mg/kg (longer extension). (Thurmon and Benson 1986)

■ REPTILES:

- Medium to small land Tortoises: Medetomidine 100–150 mcg/kg with ketamine 5–10 mg/kg IV or IM;
Freshwater Turtles: Medetomidine 150–300 mcg/kg with ketamine 10–20 mg/kg IV or IM;
Giant Land Tortoises: 200 kg Aldabra tortoise: Medetomidine 40 mcg/kg with ketamine 4 mg/kg IV or IM
Smaller Aldabra tortoises: Medetomidine 40–80 mcg/kg with ketamine 4–8 mg/kg IV or IM. Wait 30–40 minutes for peak effect;
Iguanas: Medetomidine 100–150 mcg/kg with ketamine 5–10 mg/kg IV or IM;
Reversal of all dosages with atipamezole is 4–5 times the medetomidine dose (Heard 1999)
- 20–60 mg/kg IM (McConnell and Hughey 1987)

■ SUB-HUMAN PRIMATES:

- Doses vary with regard to individual species; refer to package insert for *Ketaset*®.

■ BIRDS:

- Birds weighing:
<100 grams (canaries, finches, budgies): 0.1–0.2 mg/gm IM;
250–500 grams (parrots, pigeons): 0.05–0.1 mg/gm IM;
500 grams–3 kg (chickens, owls, hawks): 0.02–0.1 mg/gm IM;
>3 kg (ducks, geese, swans): 0.02–0.05 mg/gm IM (Booth 1988a)
- In combination with xylazine: Ketamine 10–30 mg/kg IM; Xylazine 2–6 mg/kg IM; birds less than 250 g require a higher dosage (per kg) than birds weighing greater than 250 g. Xylazine is not recommended to be used in debilitated birds because of its cardiodepressant effects.
In combination with diazepam: Ketamine 10–50 mg/kg IM; Diazepam 0.5–2 mg/kg IM or IV; doses can be halved for IV use
In combination with acepromazine: Ketamine 25–50 mg/kg IM; Acepromazine 0.5–1 mg/kg IM (Wheeler 1993)

Monitoring

- Level of anesthesia/analgesia
- Respiratory function; cardiovascular status (rate, rhythm, BP if possible)
- Monitor eyes to prevent drying or injury;
- Body temperature

Client Information

- Should only be administered by individuals familiar with its use.

Chemistry/Synonyms

A congener of phencyclidine, ketamine HCl occurs as white, crystalline powder. It has a melting point of 258–261°C, a characteristic odor, and will precipitate as the free base at high pH. One gram is soluble in 5 mL of water, and 14 mL of alcohol. The pH of the commercially-available injections are between 3.5–5.5.

Ketamine HCl may also be known as: CI-581, CL-369, CN-52372-2, ketamini hydrochloridum, *Amtech*®, *Brevinaze*®, *Calypsol*®, *Cost*®, *Inducmina*®, *Keta*®, *Keta-Hameln*®, *Ketaject*®, *Ketalin*®, *Ketanest*®, *Ketaset*®, *Ketasthesia*®, *Keta-sthetic*®, *Ketava*®, *Ketina*®, *Ketmin*®, *Ketolar*®, *Velonarcon*®, *VetaKet*®, and *Vetalar*®.

Storage/Stability/Compatibility

Ketamine injection should be stored between 15–30°C (59–86°C) and protected from light.

Solution may darken upon prolonged exposure to light which does not affect the drug's potency. Do not use if precipitates appear.

Ketamine may be mixed with sterile water for injection, D5W, and normal saline for diluent purposes. Ketamine is physically **compatible** with xylazine in the same syringe. Do not mix ketamine with barbiturates or diazepam in the same syringe or IV bag as precipitation may occur.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Ketamine HCl for Injection: 100 mg/mL in 10 mL vials; *Amtech® Ketamine Hydrochloride Injection*, USP (IVX), *Ketaject®* (Phoenix Pharmaceutical), *Ketaset®* (Fort Dodge), *Keta-sthetic®* (RXV), *Vetalar®* (Fort Dodge); *VetaKet®* (Lloyd), *Ketasthesia®* (Butler); (Rx, C-III). Approved for use in cats and sub-human primates.

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Ketamine HCl Injection: 10 mg/mL in 20 mL vials; 50 mg/mL in 10 mL vials; 100 mg/mL in 5 mL vials; *Ketalar®* (Monarch); generic; (Rx, C-III)

KETOCONAZOLE

(kee-toe-*kah*-na-zole) Nizoral®

AZOLE ANTIFUNGAL

Prescriber Highlights

- ▶ Original imidazole oral antifungal used for systemic mycoses, including aspergillosis, cryptococcal meningitis, blastomycosis, & histoplasmosis; also used as an alternative treatment of hyperadrenocorticism in dogs.
- ▶ Contraindications: Known hypersensitivity; some believe ketoconazole is contraindicated in cats
- ▶ Caution: Hepatic disease or thrombocytopenia
- ▶ Potentially teratogenic & embryotoxic; weigh risks vs. benefits
- ▶ May cause infertility in male dogs by decreasing testosterone synthesis.
- ▶ Adverse Effects: GI (anorexia, vomiting, &/or diarrhea) most common & more prevalent in cats; hepatic toxicity, thrombocytopenia, reversible lightening of haircoat, transient dose-related suppressant effect on gonadal & adrenal steroid synthesis
- ▶ Long-term treatment may be required; relatively expensive
- ▶ Drug interactions

Uses/Indications

Because of its comparative lack of toxicity when compared to amphotericin B, oral administration, and relatively good efficacy, ketoconazole has been used to treat several fungal infections in dogs, cats, and other small species. Ketoconazole is often employed with amphotericin B to enhance the efficacy of ketoconazole, and by reducing the dose of amphotericin B, decreasing its risk of toxicity. See the Dosage section or Pharmacology section for specifics. Newer antifungal agents (fluconazole, itraconazole) have advantages over ketoconazole, primarily less toxicity and/or enhanced

efficacy; however, ketoconazole can be significantly less expensive than the newer agents. Ketoconazole is considered by some to still be the drug of choice for treating histoplasmosis in dogs.

Use of ketoconazole in cats is controversial and some say it should never be used that species.

Ketoconazole is also used clinically for the medical treatment of hyperadrenocorticism in dogs. Ketoconazole appears to be a viable option (although relatively expensive) to mitotane, particularly for palliative therapy in dogs with large, malignant, or invasive tumors where surgery is not an option. Ketoconazole is also used frequently in dogs for stabilization prior to surgery. It is a reversible inhibitor of steroidogenesis, so it is usually not a viable option for long-term treatment.

Because it interferes with the metabolism of cyclosporine, it has been used to reduce the dosage necessary for cyclosporine in dogs.

Pharmacology/Actions

At usual doses and serum concentrations, ketoconazole is fungistatic against susceptible fungi. At higher concentrations for prolonged periods of time or against very susceptible organisms, ketoconazole may be fungicidal. It is believed that ketoconazole increases cellular membrane permeability and causes secondary metabolic effects and growth inhibition. The exact mechanism for these effects has not been determined, but may be due to ketoconazole interfering with ergosterol synthesis. The fungicidal action of ketoconazole may be due to a direct effect on cell membranes.

Ketoconazole has activity against most pathogenic fungi, including *Blastomyces*, *Coccidioides*, *Cryptococcus*, *Histoplasma*, *Microsporum*, and *Trichophyton*. Higher levels are necessary to treat most strains of *Aspergillus* and *Sporothrix*. Resistance to ketoconazole has been documented for some strains of *Candida albicans*.

Ketoconazole has *in vitro* activity against *Staphylococcus aureus* and *epidermidis*, *Nocardia*, enterococci, and herpes simplex virus types 1 and 2. The clinical implications of this activity are unknown.

Via inhibition of 5-lipoxygenase, ketoconazole possesses some antiinflammatory activity. The drug can suppress the immune system, probably by suppressing T-lymphocytes proliferation.

Ketoconazole also has endocrine effects as steroid synthesis is directly inhibited by blocking several P-450 enzyme systems. Measurable reductions in testosterone or cortisol synthesis can occur at dosages used for antifungal therapy, but higher dosages are generally required to reduce levels of testosterone or cortisol to be clinically useful in the treatment of prostatic carcinoma or hyperadrenocorticism. Effects on mineralocorticoids are negligible.

Pharmacokinetics

Although it is reported that ketoconazole is well absorbed after oral administration, oral bioavailability of ketoconazole tablets in dogs is highly variable. One study (Baxter et al. 1986) in six normal dogs, found bioavailabilities ranging from 0.04–0.89 (4–89%) after 400 mg (19.5–25.2 mg/kg) was administered to fasted dogs. Peak serum concentrations occur between 1 and 4.25 hours after dosing and peak serum levels ranged from 1.1–45.6 micrograms/mL. This wide interpatient variation may have significant clinical implications from both a toxicity and efficacy standpoint, particularly since ketoconazole is often used in life-threatening infections, and assays for measuring serum levels are not readily available. Administration with food may increase absorption.

Oral absorption in horses is poor. Single doses of 30 mg/kg yielded nondetectable blood levels.

Ketoconazole absorption is enhanced in an acidic environment and should not be administered (at the same time) with H₂ block-

ers or antacids (see Drug Interactions below). Whether to administer ketoconazole with meals or during a fasted state to maximize absorption is controversial. The manufacturer recommends giving with food in human patients. Dogs or cats that develop anorexia/vomiting during therapy may benefit from administration with meals.

After absorption, ketoconazole is distributed into the bile, cerumen, saliva, urine, synovial fluid, and CSF. CSF levels are generally less than 10% of those found in the serum, but may be increased if the meninges are inflamed. High levels of the drug are found in the liver, adrenals, and pituitary gland, while more moderate levels are found in the kidneys, lungs, bladder, bone marrow, and myocardium. At usual doses (10 mg/kg), attained levels are probably inadequate in the brain, testis, and eyes to treat most infections; higher dosages are required. Ketoconazole is 84–99% bound to plasma proteins and crosses the placenta (at least in rats). The drug is found in bitch's milk.

Ketoconazole is metabolized extensively by the liver into several inactive metabolites. These metabolites are excreted primarily into the feces via the bile. About 13% of a given dose is excreted into the urine and only 2–4% of the drug is excreted unchanged in the urine. Half-life in dogs is about 1–6 hours (avg. 2.7 hours).

Contraindications/Precautions/Warnings

Ketoconazole is contraindicated in patients with known hypersensitivity to it. It should be used with caution in patients with hepatic disease or thrombocytopenia.

Adverse Effects

Gastrointestinal signs of anorexia, vomiting, and/or diarrhea are the most common adverse effects seen with ketoconazole therapy and are more prevalent in cats. Anorexia may be minimized by dividing the dose and/or giving it with meals. Appetite stimulants such as oxazepam or cyproheptadine may also be of benefit in cats.

Hepatic toxicity consisting of cholangiohepatitis and increased liver enzymes has been reported with ketoconazole, and may be either idiosyncratic in nature or a dose-related phenomenon. Cats may be more prone to developing hepatotoxicity than dogs. While liver enzymes should be monitored during therapy, an increase does not necessarily mandate dosage reduction or discontinuation unless concomitant anorexia, vomiting, diarrhea, or abdominal pain is present. Thrombocytopenia has also been reported with ketoconazole therapy, but is rarely encountered. A reversible lightening of haircoat may also occur in patients treated with ketoconazole.

Ketoconazole has a transient dose-related suppressant effect on gonadal and adrenal steroid synthesis. Doses as low as 10 mg/kg depressed serum testosterone levels in dogs within 3–4 hours after dosing, but levels returned to normal within 10 hours. Doses of 30 mg/kg/day have been demonstrated to suppress serum cortisol levels in dogs with hyperadrenocorticism (see Dosages section). Dogs undergoing high dose antifungal therapy may need additional glucocorticoid support during periods of acute stress.

Reproductive/Nursing Safety

Ketoconazole is a known teratogen and embryotoxin in rats. There have been reports of mummified fetuses and stillbirths in dogs who have been treated. Ketoconazole should not be considered absolutely contraindicated in pregnant animals, however, as it is often used in potentially life-threatening infections. The benefits of therapy should be weighed against the potential risks. Ketoconazole may cause infertility in male dogs by decreasing testosterone synthesis. Testosterone production rebounds once the drug is discontinued.

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are*

no animal reproduction studies and no adequate studies in humans.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Ketoconazole is excreted in milk; use with caution in nursing dams.

Overdosage/Acute Toxicity

No reports of acute toxicity associated with overdosage were located. The oral LD₅₀ in dogs after oral administration is >500 mg/kg. Should an acute overdose occur, the manufacturer recommends employing supportive measures, including gastric lavage with sodium bicarbonate.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ketoconazole and may be of significance in veterinary patients:

- **ALCOHOL:** Ethanol may interact with ketoconazole and produce a disulfiram-like reaction (vomiting)
- **ANTACIDS:** May reduce oral absorption of ketoconazole; administer ketoconazole at least 1 hour before or 2 hours after
- **ANTIDEPRESSANTS, TRICYCLIC (amitriptyline, clomipramine):** Ketoconazole may reduce metabolism and increase adverse effects
- **BENZODIAZEPINES (midazolam, triazolam):** Ketoconazole may increase levels
- **BUSPIRONE:** Plasma concentrations may be elevated
- **BUSULFAN:** Ketoconazole may increase levels
- **CALCIUM-CHANNEL BLOCKING AGENTS (amlodipine, verapamil):** Ketoconazole may increase levels
- **CISAPRIDE:** Ketoconazole may increase cisapride levels and possibility for toxicity; use together contraindicated in humans
- **CORTICOSTEROIDS:** Ketoconazole may inhibit the metabolism of corticosteroids; potential for increased adverse effects
- **CYCLOPHOSPHAMIDE:** Ketoconazole may inhibit the metabolism of cyclophosphamide and its metabolites; potential for increased toxicity
- **CYCLOSPORINE:** Increased cyclosporine levels
- **DIGOXIN:** Ketoconazole may increase digoxin levels
- **FENTANYL/ALFENTANIL:** Ketoconazole may increase fentanyl or alfentanil levels
- **H2-BLOCKERS (ranitidine, famotidine, etc.):** Increased gastric pH may reduce ketoconazole absorption
- **HEPATOTOXIC DRUGS, OTHER:** Because ketoconazole can cause hepatotoxicity, it should be used cautiously with other hepatotoxic agents
- **ISONIAZID:** May affect ketoconazole levels and concomitant use not recommended in humans
- **IVERMECTIN:** Ketoconazole may increase risk for neurotoxicity
- **MACROLIDE ANTIBIOTICS (erythromycin, clarithromycin):** May increase ketoconazole concentrations
- **MITOTANE:** Mitotane and ketoconazole are not recommended for use together to treat hyperadrenocorticism as the adrenolytic effects of mitotane may be inhibited by ketoconazole's inhibition of cytochrome P450 enzymes
- **PHENYTOIN:** May decrease ketoconazole levels
- **PROTON-PUMP INHIBITORS (omeprazole, etc.):** Increased gastric pH may reduce ketoconazole absorption

- **QUINIDINE:** Ketoconazole may increase quinidine levels
- **RIFAMPIN:** May decrease ketoconazole levels; ketoconazole may increase rifampin levels
- **SUCRALFATE:** May reduce absorption of ketoconazole
- **SULFONYLUREA ANTIDIABETIC AGENTS** (e.g., **glipizide**, **glyburide**): Ketoconazole may increase levels; hypoglycemia possible
- **THEOPHYLLINE:** Ketoconazole may decrease serum theophylline concentrations in some patients; theophylline levels should be monitored
- **VINCISTINE/VINBLASTINE:** Ketoconazole may inhibit vinca alkaloid metabolism and increase levels
- **WARFARIN:** Ketoconazole may cause increased prothrombin times in patients receiving warfarin or other coumarin anticoagulants

Doses

Note: Clinical antifungal effects may require 10–14 days of therapy

■ DOGS:

For coccidioidomycosis:

- a) For the systemic form of the disease: 5–10 mg/kg PO twice daily; For the CNS form: 15–20 mg/kg PO twice daily. Treatment should persist for a minimum of 3–6 months. Animals with bony lesions or relapses after discontinuing therapy, give lifelong therapy at 5 mg/kg PO every other day. (Macy 1988)
- b) 10–30 mg/kg PO divided twice a day, most animals need to be treated for 6–12 months (Taboada 2000)

For blastomycosis:

- a) 10 mg/kg PO twice daily (15–20 mg/kg PO twice daily if CNS involvement) for at least 3 months with amphotericin B: initially at 0.25–0.5 mg/kg every other day IV. If tolerated, increase dose to 1 mg/kg until 4–5 mg/kg total dose is administered. See amphotericin B monograph for more information. (Macy 1988)
- b) Ketoconazole 20 mg/kg/day PO once daily or divided twice daily; 40 mg/kg divided twice daily for ocular or CNS involvement (for at least 2–3 months or until remission then start maintenance) with amphotericin B 0.15–0.5 mg/kg IV 3 times a week. When a total dose of amphotericin B reaches 4–6 mg/kg, start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month or use ketoconazole at 10 mg/kg PO either once daily, divided twice daily or ketoconazole at 2.5–5 mg/kg PO once daily. If CNS/ocular involvement, use ketoconazole at 20–40 mg/kg PO divided twice daily (Greene, O'Neal, and Barsanti 1984)

For histoplasmosis:

- a) 10 mg/kg PO once a day or twice a day for at least 3 months. Treat at least 30 days after complete resolution of clinical disease. If patient relapses, retreat as above then put on maintenance 5 mg/kg PO every other day indefinitely. For acute cases: use with amphotericin B (see blastomycosis recommendation by same author above) (Macy 1988)
- b) Ketoconazole 10–20 mg/day PO once daily or divided twice daily (for at least 2–3 months or until remission then start maintenance) with amphotericin B at 0.15–0.5 mg/kg IV 3 times a week. When a total dose of amphotericin B reaches 2–4 mg/kg start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month or use ketoconazole at 10 mg/kg PO either once daily, divided twice daily or at 2.5–5 mg/kg PO once daily (Greene, O'Neal, and Barsanti 1984)

For aspergillosis:

- a) 20 mg/kg PO for at least 6 weeks; may require long-term/maintenance therapy (Macy 1988)

- b) For nasal aspergillosis: 10 mg/kg PO once daily (q24h) or 5 mg/kg PO q12h. Treatment requires many weeks and should continue for 1 month beyond last detection of infection. Itraconazole somewhat more effective. (Greene, Hartmann et al. 2006)

For cryptococcosis:

- a) Amphotericin B 0.15–0.4 mg/kg IV 3 times a week with flucytosine 150–175 mg/kg PO divided three to four times a day. When a total dose of amphotericin B reaches 4–6 mg/kg start maintenance dosage of amphotericin B at 0.15–0.25 mg/kg IV once a month with flucytosine at dosage above or with ketoconazole at 10 mg/kg PO once daily or divided twice daily (Greene, O'Neal, and Barsanti 1984)

For fungal myocarditis:

- a) 10 mg/kg PO three times daily (Ogburn 1988)

For Candidiasis:

- a) 10 mg/kg PO once daily (q24h) or 5 mg/kg PO q12h. Treatment requires many weeks and should continue for 1 month beyond last detection of infection. Itraconazole somewhat more effective. (Greene, Hartmann et al. 2006)

For Sporotrichosis:

- a) 15 mg/kg PO q12h. Treatment requires many weeks and should continue for 1 month beyond last detection of infection. (Greene, Hartmann et al. 2006)

For Malassezia dermatitis:

- a) 5–10 mg/kg PO twice a day for 30 days. Often used with therapeutic shampoos containing selenium disulfide, miconazole, ketoconazole or chlorhexidine. Underlying conditions must be identified and remedied or condition will recur. (Noxon 1997)
- b) 5–10 mg/kg PO daily for 10 days, then every other day for an additional 10 days. This regimen resolves the majority of cases, but some may need higher dosages. (Muse 2000)
- c) Initial dose is 5 mg/kg twice daily for 21–30 days, may increase to 10 mg/kg PO twice daily if poor response. Absorption is enhanced when administered with food and is ideal in an acid environment. (McDonald 1999)
- d) 2.5–10 mg/kg PO once daily (q24h) for 7–14 days; once a good response is seen taper to every other day (q48h) and continue until a complete remission occurs. In the rare case when ketoconazole is ineffective or intolerance or toxicity is seen, itraconazole or fluconazole can be used. (Rosenkrantz 2006a)

For treatment of hyperadrenocorticism:

- a) 5 mg/kg PO twice a day for 7 days. If no problems with appetite or icterus, increase dose to 10 mg/kg PO twice a day. Repeat ACTH response test in 14 days (animal stays on drug). If not satisfactorily controlled, increase to 15 mg/kg twice a day. Goal is pre- and post-ACTH plasma cortisol levels of less than 5 mcg/kg. (Feldman 2000)
- b) Begin with a dose of 5 mg/kg q12h for 5–7 days and if there are no side effects (usually GI-related), increase dose to 10 mg/kg q12h for 10–14 days and perform ACTH stimulation test. Plasma cortisol levels should be between 0.7–1.8 mcg/dl if ketoconazole is to be effective. Over 25% of cases do not respond to ketoconazole and many cases that do respond, require doses of between 15–20 mg/kg q12h. Because of unpredictable efficacy, high occurrence of adverse effects, twice daily dosing, and expense, ketoconazole usage for PDH has been limited. (Church 2004)
- c) For palliative treatment of canine Cushing's syndrome: 15 mg/kg PO q12h (Lorenz and Melendez 2002b)

To reduce the dosage requirements of cyclosporine:

- a) Ketoconazole at 5–10 mg/kg PO per day can be administered concurrently with cyclosporine; in these patients the cyclosporine dose can be reduced (approximately half) or possibly tapered sooner than in patients not receiving the combination. Addition of ketoconazole is particularly useful in allergic patients with concurrent *Malassezia* dermatitis or otitis. (Hnilica 2006)
- b) To treat perianal fistula: ketoconazole 7.5 mg/kg PO twice daily; cyclosporine 0.5–0.75 mg PO twice daily. (O'Neill, Edwards et al. 2001)
- c) For atopic dermatitis: Cyclosporine at 5–7 mg/kg/day or less. Ideally should be given on an empty stomach, but if causes GI upset administration with food may help. In large dogs, administration of cyclosporine at 2.5 mg/kg/day with ketoconazole (5 mg/kg/day) may give good results and reduce expenses. (White 2007)
- d) As an alternative immunosuppressive agent for refractory IMHA, especially those that are non-regenerative: Cyclosporine at 5–10 mg/kg PO divided twice daily to achieve plasma trough levels of >200 ng/mL (**Note:** reference states >200 mg/mL, but it is believed this is a typo). Large breed dogs can be dosed concurrently with ketoconazole (10 mg/kg/day) to allow reduction of cyclosporine dose. (Macintire 2006d)

■ CATS:

Note: Use of ketoconazole in cats is somewhat controversial and some clinicians recommend that it not be used in this species because of its toxic potential. Consider using itraconazole in its place.

- a) For coccidioidomycosis: 10–30 mg/kg PO divided twice a day, most animals need to be treated for 6–12 months (Taboada 2000)
- b) For coccidioidomycosis: 50 mg per cat PO once daily; or 25–75 mg per cat q12–48h. Treatment requires many months (9–12 on average) and should continue for 1 month beyond last detection of infection. (Greene, Hartmann et al. 2006)
- c) For blastomycosis: 10 mg/kg q12h PO (for at least 60 days) with amphotericin B: 0.25 mg/kg in 30 mL D5W IV over 15 minutes q48h. Continue amphotericin B therapy until a cumulative dose of 4 mg/kg is given or until BUN >50 mg/dl. If renal toxicity does not develop, may increase dose to 0.5 mg/kg of amphotericin B. (Legendre 1989)
- d) For cryptococcosis: 10 mg/kg twice daily. Very useful for this condition in cats, but at this dosage can produce anorexia and debility. (Legendre 1995)
- e) For aspergillosis: 10 mg/kg PO q12h (Legendre 1989)
- f) For dermatophytosis: Usually reserved for when griseofulvin ineffective or not tolerated. 10 mg/kg PO once daily with an acidic meal. Prolonged course of therapy required. Begin taking cultures after 4 weeks of treatment. Continue therapy for 2 weeks beyond clinical cure and when 2–3 negative cultures are obtained at weekly intervals. (Frank 2000)
- g) For Sporotrichosis: 5–10 mg/kg PO q12–24h. Treatment requires many weeks (2–4 months on average) and should continue for 1 month beyond last detection of infection. (Greene, Hartmann et al. 2006)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: 10–40 mg/kg per day PO for 14 days (Ivey and Morrisey 2000)
- b) Hamsters, Gerbils, Mice, Rats, Guinea pigs, Chinchillas: For systemic mycoses/candidiasis: 10–40 mg/kg per day PO for 14 days (Adamcak and Otten 2000)

■ BIRDS:

For susceptible fungal infections:

- a) For severe refractory candidiasis in Psittacines: 5–10 mg/kg as a gavage twice daily for 14 days. For local effect in crop dissolve ¼ tablet (50 mg) in 0.2 mL of 1 N hydrochloric acid and add 0.8 mL of water. Solution turns pale pink when dissolved. Add mixture to food for gavage.
To add to water for most species: 200 mg/L for 7–14 days. As drug is not water soluble at neutral pH, dissolve in acid prior to adding to water (see above).
To add to feed for most species: 10–20 mg/kg for 7–14 days. Add to favorite food or add to mash. (Clubb 1986)
- b) 20–30 mg/kg PO twice daily (based on the kinetics determined in a single trial of Moluccan Cockatoos) (Flammer 2003a)
- c) Ratites: 5–10 mg/kg PO once daily (Jenson 1998)

■ REPTILES:

- a) For susceptible infections: For most species: 15–30 mg/kg PO once daily for 2–4 weeks (Gauvin 1993)
- b) For fungal shell diseases in turtles/tortoises: 25 mg/kg PO once a day for 2–4 weeks (Roskopf 1986)

Monitoring

- Liver enzymes with chronic therapy (at least every 2 months; some clinicians say monthly)
- CBC with platelets
- Efficacy and other adverse effects

Client Information

- If animal develops gastrointestinal signs divide dose and administer with meals.
- Long-term therapy with adequate dosing compliance is usually necessary for successful results
- Clients must be committed for both the financial and dosing burdens associated with therapy.

Chemistry/Synonyms

An imidazole antifungal agent, ketoconazole occurs as a white to slightly beige powder with pK_a s of 2.9 and 6.5. It is practically insoluble in water.

Ketoconazole may also be known as ketoconazolum, and R-41400; many trade names are available.

Storage/Stability

Ketoconazole tablets should be stored at room temperature in well-closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ketoconazole Tablets: 200 mg (scored); *Nizoral*® (Janssen); generic; (Rx)

Topical forms are also available.

KETOPROFEN

(kee-toe-*proe*-fen) Ketofen®

NON-STEROIDAL ANTIINFLAMMATORY AGENT

Prescriber Highlights

- ▶ **Nonsteroidal antiinflammatory agent used in horses, cats (short-term) & dogs**
- ▶ **Contraindications:** Hypersensitivity to ketoprofen
- ▶ **Cautions:** GI ulceration or bleeding, hypoproteinemia, breeding animals (especially late in pregnancy), significant renal or hepatic impairment; may mask the signs of infection (inflammation, hyperpyrexia)
- ▶ **Adverse Effects:** Horses: Potentially, gastric mucosal damage & GI ulceration, renal crest necrosis, & mild hepatitis may occur. Dogs: Vomiting, anorexia, & GI ulcers
- ▶ **Do not administer intra-arterially & avoid SC injections**
- ▶ **Drug-drug; drug-lab interactions**

Uses/Indications

Ketoprofen is labeled for use in horses for the alleviation of inflammation and pain associated with musculoskeletal disorders. Like flunixin (and other NSAIDs), ketoprofen potentially has many other uses in a variety of species and conditions. There are approved dosage forms for dogs and cats in Europe and Canada. Some consider ketoprofen to be the NSAID of choice for use short-term for analgesia in cats.

Pharmacology/Actions

Ketoprofen exhibits actions similar to that of other nonsteroidal antiinflammatory agents in that it possesses antipyretic, analgesic and antiinflammatory activity. Its purported mechanism of action is the inhibition of cyclooxygenase catalysis of arachidonic acid to prostaglandin precursors (endoperoxides), thereby inhibiting the synthesis of prostaglandins in tissues. Ketoprofen purportedly has inhibitory activity on lipoxygenase, whereas flunixin reportedly does not at therapeutic doses. *In vitro* studies have not confirmed lipoxygenase activity in studied species.

The S (+) enantiomer is associated with anti-prostaglandin activity and toxicity and the R (-) form analgesia without the GI effects.

Pharmacokinetics

In species studied (rats, dog, man), ketoprofen is rapidly and nearly completely absorbed after oral administration. The presence of food or milk decreases oral absorption. Oral absorption characteristics in horses were not located. It has been reported that when comparing IV vs. IM injections in horses, the areas under the curve are relatively equivalent.

While distribution characteristics are not well described, the drug does enter synovial fluid and is highly bound to plasma proteins (99% in humans, and approximately 93% in horses). In horses, the manufacturer reports that the onset of activity is within 2 hours and peak effects 12 hours post dose.

Ketoprofen is eliminated via the kidneys both as a conjugated metabolite and unchanged drug. The elimination half-life in horses is approximately 1.5 hours.

Contraindications/Precautions/Warnings

While the manufacturer states that there are no contraindications to the drug's use (other than previous hypersensitivity to ketoprofen), it should be used only when the potential benefits outweigh the risks in cases where GI ulceration or bleeding is evident or in patients with significant renal or hepatic impairment. Ketoprofen may mask the clinical signs of infection (inflammation, hyperpyrexia). Because ketoprofen is highly protein bound, patients with hypoproteinemia may have increased levels of free drug, thereby increasing the risks for toxicity.

Adverse Effects

Because ketoprofen is a relatively new agent, its adverse effect profile in horses has not been clearly elucidated. Preliminary studies and reports indicate that ketoprofen appears relatively safe to use in horses and may have a lower incidence of adverse effects than either phenylbutazone or flunixin. Potentially, gastric mucosal damage and GI ulceration, renal crest necrosis, and mild hepatitis may occur.

Do not administer intra-arterially and avoid SC injections. While not labeled for IM use in horses, it reportedly is effective and may only cause occasional inflammation at the injection site.

In dogs or cats, ketoprofen may cause vomiting, anorexia, and GI ulcers.

Reproductive/Nursing Safety

The manufacturer cautions against ketoprofen's use in breeding animals because effects on fertility, pregnancy, or fetal health have not been established in horses. However, rat and mice studies have not demonstrated increased teratogenicity or embryotoxicity. Rabbits receiving twice the human dose exhibited increased embryotoxicity, but not teratogenicity. Because non-steroidal antiinflammatory agents inhibit prostaglandin synthesis, adversely affecting neonatal cardiovascular systems (premature closure of patent ductus), ketoprofen should not be used late in pregnancy. Studies in male rats demonstrated no changes in fertility. In humans, the FDA categorizes this drug as category **B** for use during the first two trimesters of pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is presently unknown whether ketoprofen enters equine milk. Ketoprofen does enter canine milk; use with caution.

Overdosage/Acute Toxicity

Horses given ketoprofen at doses up to 11 mg/kg administered IV once daily for 15 days exhibited no signs of toxicity. Severe laminitis was observed in a horse given 33 mg/kg/day (15X over labeled dosage) for 5 days. Anorexia, depression, icterus, and abdominal swelling were noted in horses given 55 mg/kg/day (25X labeled dose) for 5 days. Upon necropsy, gastritis, nephritis, and hepatitis were diagnosed in this group.

There were 24 exposures to ketoprofen reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 9 were dogs with 1 showing clinical signs and the remaining 15 cases were cats that showed no clinical signs. Common findings in dogs include vomiting.

Humans have survived oral ingestions of up to 5 grams. The LD₅₀ in dogs after oral ingestion has been reported to be 2000 mg/kg.

This medication is a NSAID. As with any NSAID, overdosage can lead to gastrointestinal and renal effects. Decontamination with emetics and/or activated charcoal is appropriate. For doses where GI effects are expected, the use of gastrointestinal protectants

is warranted. If renal effects are also expected, fluid diuresis is warranted.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ketoprofen and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (*gentamicin, amikacin*, etc.): Increased risk for nephrotoxicity
- **ANTICOAGULANTS** (*heparin, LMWH, warfarin*): Increased risk for bleeding possible
- **ASPIRIN**: When aspirin is used concurrently with ketoprofen, plasma levels of ketoprofen could decrease and an increased likelihood of GI adverse effects (blood loss) could occur. Concomitant administration of aspirin with ketoprofen cannot be recommended.
- **BISPHOSPHONATES** (*alendronate*, etc.): May increase risk for GI ulceration
- **CORTICOSTEROIDS**: Concomitant administration with NSAIDs may significantly increase the risks for GI adverse effects
- **CYCLOSPORINE**: May increase risk for nephrotoxicity
- **FLUCONAZOLE**: May increase NSAID levels
- **FUROSEMIDE**: Ketoprofen may reduce the saluretic and diuretic effects of furosemide
- **HIGHLY PROTEIN BOUND DRUGS** (e.g., *phenytoin, valproic acid, oral anti-coagulants*, other *antiinflammatory agents, salicylates, sulfonamides*, and the *sulfonylurea antidiabetic agents*): Because ketoprofen is highly bound to plasma proteins (99%), it potentially could displace other highly bound drugs; increased serum levels and duration of actions may occur. Although these interactions are usually of little concern clinically, use together with caution.
- **METHOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution.
- **PROBENECID**: May cause a significant increase in serum levels and half-life of ketoprofen

Laboratory Considerations

Ketoprofen may cause:

- Falsely elevated **blood glucose** values when using the glucose oxidase and peroxidase method using ABTS as a chromogen;
- Falsely elevated **serum bilirubin** values when using DMSO as a reagent;
- Falsely elevated **serum iron** concentrations using the Ramsey method, or falsely decreased serum iron concentrations when using bathophenanthroline disulfonate as a reagent

Doses

■ DOGS:

- As an antiinflammatory/analgesic:
 - a) 2 mg/kg IV one time (Hardie 2000)
 - b) For osteoarthritis unresponsive to aspirin: 0.5–1 mg/kg PO twice daily with food; decrease the dose by 50% when giving to geriatric patients (Trepanier 1999)
 - c) For post-operative pain control: 1–2 mg/kg IV, IM once daily for 2–3 days duration (Tranquilli 2003)
 - d) For post-operative pain control: 1–2 mg/kg IV, SC once daily for 3 days duration after surgery; or 1 mg/kg PO once daily for 5 days, after surgery (Hansen 2003b)
 - e) For acute indications: 2 mg/kg SC, IM, IV once daily for up to 3 consecutive day. If preferred after one injection treatment may be followed on the next day with tablets at 1 mg/

kg PO per day and continued on successive days for up to 4 days (i.e., up to 5 days in total). For chronic pain: 0.25 mg/kg PO once daily for up to 30 days. (Label Information *Ketofen* 1%; *Ketofen*® Tablets—Merial U.K.)

■ CATS:

- As an antiinflammatory/analgesic:
 - a) 2 mg/kg IV one time (Hardie 2000)
 - b) For mild to moderate pain: 1–2 mg/kg SC, IM initially, then 0.5–1 mg PO, SC once daily; not recommended to treat more than 5 days (Nieves 2002)
 - c) For post-operative pain control: 1–2 mg/kg IV, SC once daily for 3 days duration after surgery; or 1 mg/kg PO once daily for 3 days, after surgery (Hansen 2003b)
 - d) 2 mg/kg SC once daily for up to 3 consecutive days. If preferred after one injection treatment may be followed on the next day with tablets at 1 mg/kg and continued on successive days for up to 4 days (i.e., up to 5 days in total). (Label Information *Ketofen* 1%; *Ketofen*® Tablets—Merial U.K.)

■ RABBITS/RODENTS/SMALL MAMMALS:

- a) Rabbits: For chronic pain/antiinflammatory: 1 mg/kg IM q12–24h (Ivey and Morrissey 2000)
- b) Rats: 5 mg/kg SC (Adamcak and Otten 2000)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- a) For labeled indications: 2.2 mg/kg (1 mL/100 lbs) IV once daily for up to 5 days (Package insert; *Ketofen*®)
- b) As an adjunctive treatment for laminitis: 2.2 mg/kg IV once daily (Brumbaugh, Lopez et al. 1999)

■ CATTLE:

- a) 3 mg/kg IV or deep IM once daily for up to 3 days; withdrawal times (U.K.) are meat: 4 days; milk: 0 days (Label information *Comforion Vet*®—Merial U.K.)
- b) 3.3 mg/kg; duration of effect 24 hours; appropriate withdrawal times: 24 hour for milk; 7 days for meat. (Walz 2006b)

■ SWINE:

- a) 3 mg/kg IM once daily for up to 3 days; withdrawal times (U.K.) for meat: 4 days (Label information *Comforion Vet*®—Merial U.K.)

■ BIRDS:

- a) As an antiinflammatory analgesic 2 mg/kg IM q8–24 hours (Clyde and Paul-Murphy 2000)

Monitoring

■ Efficacy

- Adverse Effects (occasional liver or renal function tests are recommended with long-term therapy)

Chemistry/Synonyms

A propionic acid derivative nonsteroidal antiinflammatory agent (NSAID), ketoprofen occurs as an off-white to white, fine to granular powder. It is practically insoluble in water, but freely soluble in alcohol at 20°C. Ketoprofen has a pK_a of 5.9 in a 3:1 methanol:water solution. Ketoprofen has both an S enantiomer and R enantiomer. The commercial product contains a racemic mixture of both. The S (+) enantiomer has greater antiinflammatory potency than the R (–) form.

Ketoprofen may also be known as ketoprofenum and RP-19583; many trade names are available.

Storage/Stability/Compatibility

Ketoprofen oral capsules should be stored at room temperature in tight, light resistant containers. The veterinary injection should be stored at room temperature. Compatibility studies with inject-

able ketoprofen and other compounds have apparently not been published.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Ketoprofen Injection: 100 mg/mL in 50 mL and 100 mL multi-dose vials; *Ketofen*® (Fort Dodge), generic (Phoenix Pharmaceutical), (Rx). Approved for use in horses not intended for food.

In Canada and the U.K., there are approved oral dosage forms (5, 10, 20 mg tablets) and an injectable form (10 mg/mL) for use in dogs and cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Ketoprofen Capsules: 50 mg & 75 mg; generic; (Rx)

Ketoprofen Extended-Release Capsules: 100 mg, 150 mg and 200 mg; Ketoprofen (Andrx); (Rx)

KETOROLAC TROMETHAMINE

(kee-toe-role-ak) Toradol®

NON-STEROIDAL ANTIINFLAMMATORY AGENT

Prescriber Highlights

- ▶ **NSAID used primarily for short-term analgesia**
- ▶ **Contraindications:** Active GI ulcers or history of hypersensitivity to the drug
- ▶ **Relatively contraindicated:** Hematologic, renal, or hepatic disease
- ▶ **Caution:** History of gastric ulcers, heart failure
- ▶ **Adverse Effects:** GI ulcers & perforation, renal effects possible with chronic use; consider co-dosing with misoprostol/sucralfate in dogs to reduce chances of ulcers

Uses/Indications

Ketorolac is used primarily for its analgesic effects for short-term treatment of mild to moderate pain in dogs and rodents. The duration of analgesic effect in dogs is about 8–12 hours, but because of the availability of approved, safer NSAIDs for dogs, its use is questionable.

Pharmacology/Actions

Like other NSAIDs, ketorolac exhibits analgesic, antiinflammatory, and antipyretic activity probably through its inhibition of cyclooxygenase with resultant impediment of prostaglandin synthesis. Ketorolac may exhibit a more potent analgesic effect than some other NSAIDs. It inhibits both COX-1 and COX-2 receptors.

Pharmacokinetics

After oral administration, ketorolac is rapidly absorbed; in dogs peak levels occur in about 50 minutes and oral bioavailability is about 50–75%.

Ketorolac is distributed marginally through the body. It does not appear to cross the blood-brain barrier and is highly bound to plasma proteins (99%). The volume of distribution in dogs is reported to be about 0.33–0.42 L/kg (similar in humans). The drug does cross the placenta.

Ketorolac is primarily metabolized via glucuronidation and hy-

droxylation. Both unchanged drug and metabolites are excreted mainly in the urine. Patients with diminished renal function will have longer elimination times than normal. In normal dogs, the elimination half-life is between 4–8 hours.

Contraindications/Precautions/Warnings

Ketorolac is relatively contraindicated in patients with a history of, or preexisting, hematologic, renal or hepatic disease. It is contraindicated in patients with active GI ulcers or with a history of hypersensitivity to the drug. It should be used cautiously in patients with a history of GI ulcers, or heart failure (may cause fluid retention), and in geriatric patients. Animals suffering from inflammation secondary to concomitant infection, should receive appropriate antimicrobial therapy.

Because ketorolac has a tendency to cause gastric erosion and ulcers in dogs, long-term use (>3 days) is not recommended in this species.

Adverse Effects

Ketorolac use is limited in domestic animals because of its adverse effect profile and a lack of veterinary-labeled products. The primary issue in dogs is its GI toxicity. GI ulceration can be common if the drug is used chronically. Most clinicians who have used this medication in dogs limit treatment to less than 3 days and give misoprostol with or without sucralfate concurrently. Like other NSAIDs, platelet inhibition, renal, and hepatic toxicity are also possible with this drug.

Reproductive/Nursing Safety

Ketorolac does cross the placenta. In humans, the FDA categorizes this drug as category **C** for use during the *first two trimesters of pregnancy* (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In humans, all NSAIDs are assigned to category **D** for use during pregnancy during the *third trimester* or near delivery (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Most NSAIDs are excreted in milk. Ketorolac was detected in human breast milk at a maximum milk:plasma ratio of 0.037. It is unlikely to pose great risk to nursing offspring.

Overdosage/Acute Toxicity

Limited information is available. The oral LD₅₀ is 200 mg/kg in mice. GI effects, including GI ulceration are likely in overdoses in small animals. Metabolic acidosis was reported in one human patient. Consider GI emptying in large overdoses; patients should be monitored for GI bleeding. Treat ulcers with sucralfate; consider giving misoprostol early.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving ketorolac and may be of significance in veterinary patients:

- **ACE INHIBITORS:** Increased risk for nephrotoxicity
- **ALPRAZOLAM:** Hallucinations reported in some human patients taking with ketorolac
- **AMINOGLYCOSIDES** (gentamicin, amikacin, etc.): Increased risk for nephrotoxicity
- **ANTICOAGULANTS** (heparin, LMWH, warfarin): Increased risk for bleeding possible
- **ASPIRIN:** Increased likelihood of GI adverse effects (blood loss)

- **BISPHOSPHONATES** (alendronate, etc.): May increase risk for GI ulceration
- **CORTICOSTEROIDS**: Concomitant administration with NSAIDs may significantly increase the risks for GI adverse effects
- **CYCLOSPORINE**: May increase risk for nephrotoxicity
- **FLUCONAZOLE**: May increase NSAID levels
- **FLUOXETINE**: Hallucinations reported in some human patients taking with ketorolac
- **FUROSEMIDE**: Ketorolac may reduce the saluretic and diuretic effects of furosemide
- **METHOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- **MUSCLE RELAXANTS, NONDEPOLARIZING**: Ketorolac may potentiate effects
- **PROBENECID**: May cause a significant increase in serum levels and half-life of ketorolac

Doses

- **DOGS**:
 - a) As an analgesic: 0.5 mg/kg IV three times daily or 0.3 mg/kg PO twice daily. Repeated doses have considerable potential for causing GI or renal toxicity. Treated dogs should receive misoprostol. (Dowling 2000)
 - b) As an analgesic: 0.3–0.5 mg/kg IV, IM q8–12h for one or two doses (Scherk 2003a)
- **CATS**:
 - a) As an analgesic: 0.25 mg/kg IM q8–12h for one or two doses (Scherk 2003a)
- **GOATS**:
 - a) As an analgesic: 0.3–0.7 mg/kg IV, IM, SC, PO three times daily (Resources 2000)
- **RABBITS/RODENTS/SMALL MAMMALS**:
 - a) As an analgesic: Mice: 0.7–10 mg/kg PO once daily. Rats: 3–5 mg/kg PO once to twice a day; 1 mg/kg IM once to twice a day (Huerkamp 2000)

Monitoring

- Analgesic/antiinflammatory efficacy
- GI: appetite, feces (occult blood, diarrhea)

Client Information

- Notify veterinarian if signs of GI distress (anorexia, vomiting, diarrhea, black feces, or blood in stool) occur, or if the animal becomes depressed.

Chemistry/Synonyms

A carboxylic acid derivative nonsteroidal antiinflammatory agent, ketorolac tromethamine occurs as an off-white crystalline powder with a pKa of 3.54 (in water). More than 500 mg are soluble in one mL of water at room temperature. The commercially available injection is a clear, slightly yellow solution with a pH of 6.9–7.9. Sodium chloride is added to make the solution isotonic.

Ketorolac tromethamine may also be known as RS-37619-00-31-3; many trade names are available.

Storage/Stability/Compatibility

Both the tablets and injection should be stored at room temperature and protected from light. Protect the tablets from excessive humidity. It is recommended not to mix the injection with other drugs in the same syringe. The injection is stable for at least 48 hours in commonly used IV solutions.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Ketorolac Tromethamine Tablets: 10 mg; generic; (Rx)

Ketorolac Tromethamine Injection: 15 mg/mL & 30 mg/mL in 1 mL, 2 mL vials, & 10 mL multiple-dose vials; generic; (Rx)

A topical ophthalmic preparation is also available; see the ophthalmology section in the appendix for further information.

L-Asparaginase — see **Asparaginase**

L-Thyroxine — see **Levothyroxine Sodium**

Lactated Ringer's — see the appendix section on intravenous fluids

LACTULOSE

(lak-tyoo-lose) Cephulac®

DISACCHARIDE LAXATIVE/AMMONIA REDUCER

Prescriber Highlights

- Disaccharide laxative & reducer of blood ammonia levels
- Adverse Effects: Flatulence, gastric distention, cramping, etc.; diarrhea & dehydration are signs of overdosage
- Cats dislike the taste of lactulose & administration may be difficult
- May alter insulin requirements in diabetics

Uses/Indications

The primary use of lactulose in veterinary medicine is to reduce ammonia blood levels in the prevention and treatment of hepatic encephalopathy (portal-systemic encephalopathy; PSE) in small animals and pet birds. It is also used as a laxative in small animals.

Pharmacology/Actions

Lactulose is a disaccharide (galactose/fructose) that is not hydrolyzable by mammalian and, probably, avian gut enzymes. Upon reaching the colon, lactulose is metabolized by the resident bacteria resulting in the formation of low molecular weight acids (lactic, formic, acetic) and CO₂. These acids have a dual effect; they increase osmotic pressure drawing water into the bowel causing a laxative effect and also acidify colonic contents. The acidification causes ammonia NH₃ (ammonia) to migrate from the blood into the colon where it is trapped as [NH₄]⁺ (ammonium ion) and expelled with the feces.

Pharmacokinetics

In humans, less than 3% of an oral dose of lactulose is absorbed (in the small intestine). The absorbed drug is not metabolized and excreted unchanged in the urine within 24 hours.

Contraindications/Precautions/Warnings

Lactulose syrup contains some free lactose and galactose, and may alter the insulin requirements in diabetic patients. In patients with preexisting fluid and electrolyte imbalances, lactulose may exacerbate these conditions if it causes diarrhea; use cautiously.

Adverse Effects

Signs of flatulence, gastric distention, cramping, etc. are not uncommon early in therapy, but generally abate with time. Diarrhea and dehydration are signs of overdosage; dosage should be reduced.

Cats dislike the taste of lactulose and administration may be difficult.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether lactulose is excreted in milk, but it would be unexpected.

Overdosage/Acute Toxicity

Excessive doses may cause flatulence, diarrhea, cramping, and dehydration. Replace fluids and electrolytes if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lactulose and may be of significance in veterinary patients:

- **ANTACIDS, ORAL:** Antacids (non-adsorbable) may reduce the colonic acidification effects (efficacy) of lactulose
- **LAXATIVES, OTHER:** Do not use lactulose with other laxatives as the loose stools that are formed can be falsely attributed to the lactulose with resultant inadequate therapy for hepatic encephalopathy
- **NEOMYCIN:** Theoretically, orally administered antibiotics (e.g., neomycin) could eliminate the bacteria responsible for metabolizing lactulose, thereby reducing its efficacy. However, some data suggests that synergy may occur when lactulose is used with an oral antibiotic (e.g., neomycin) for the treatment of hepatic encephalopathy; enhanced monitoring of lactulose efficacy is probably warranted in cases where an oral antibiotic is added to the therapy

Doses

■ DOGS:

For hepatic encephalopathy:

- a) 15–30 mL PO four times a day; adjust the dosage to produce 2–3 soft stools per day (Cornelius and Bjorling 1988)
- b) Give 5 mL per 2.5 lbs. of body weight divided three times a day, may increase as necessary to achieve 2–3 soft stools per day. If patient is in hepatic encephalopathy crisis, may give 20–60 mL via stomach tube every 4–6 hours or may give as an intermittent enema (diluted with water) to total 200–300 mL (300–450 grams). (Tams 2000)
- c) 5–15 mL PO three times daily; adjust dose to induce 2–3 soft stools per day; reduce dosage if diarrhea develops. In certain cases, neomycin with lactulose may be superior to either drug alone. (Hardy 1985)
- d) 1–10 mL PO three times daily; adjust dose to give 3–4 soft stools per day; reduce dose if diarrhea develops. May also give via enema in treating severe hepatic encephalopathy. (Twedt 2005a)

For constipation:

- a) 1 mL per 4.5 kg of body weight PO q8h initially, then adjust as needed (Kirk 1986)

■ CATS:

For hepatic encephalopathy:

- a) 0.25–1 mL PO; individualize dosage until semi-formed stools are produced (Center, Hornbuckle, and Scavelli 1986)

For constipation:

- a) 1 mL per 4.5 kg of body weight PO q8h initially, then adjust as needed (Kirk 1986)
- b) 0.5 mL/kg q8–12h PO (Sherding 1989); (Washabau and Holt 2000)

■ BIRDS:

For hepatic encephalopathy; to stimulate appetite, improve intestinal flora:

- a) Cockatiel: 0.03 mL PO two to three times a day; Amazon: 0.1 mL PO two to three times a day. Reduce dosage if diarrhea develops. May be used for weeks. (Clubb 1986)

■ REPTILES:

As a laxative:

- a) Green Iguana: 0.3 mL/kg PO q12h (Wilson 2002a)

Monitoring

- Clinical efficacy (2–3 soft stools per day) when used for PSE
- In long-term use (months) or in patients with preexisting fluid/electrolyte problems, serum electrolytes should be monitored.

Client Information

- Contact veterinarian if diarrhea develops.
- When lactulose is used for hepatic encephalopathy, contact veterinarian if signs worsen or less than 2–3 soft stools are produced per day.

Chemistry/Synonyms

A synthetic derivative of lactose, lactulose is a disaccharide containing one molecule of galactose and one molecule of fructose. It occurs as a white powder that is very slightly soluble in alcohol and very soluble in water. The commercially available solutions are viscous, sweet liquids with an adjusted pH of 3–7.

Lactulose may also be known as lactulosum; many trade names are available.

Storage/Stability

Lactulose syrup should be stored in tight containers, preferably at room temperature; avoid freezing. If exposed to heat or light, darkening or cloudiness of the solution may occur, but apparently this does not affect drug potency.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Lactulose Solution: 10 g lactulose per 15 mL (<1.6 g galactose, <1.2 g lactose and < or = to 1.2 g of other sugars) in 30 mL, 237 mL, 240 mL, 473 mL, 480 mL, 946 mL, 960 mL, 1893 mL, 1920 mL and 3785 mL, 1.89 L and 1.9 L, and UD 30 mL; *Cephulac*® (Hoechst-Marion Roussel); *Cholac*® (Alra); *Constulose*® and *Enulose*® (Alpharma); generic; (Rx)

Lactulose Crystals for Reconstitution: Lactulose (<0.3 g galactose and lactose/10 g) in 10 g and 20 g; *Kristalose*® (Bertek); (Rx)

LEFLUNOMIDE

(le-*floo*-noh-myde) Arava

IMMUNOMODULATING AGENT

Prescriber Highlights

- ▶ Immunomodulating drug that may be useful in dogs for treating a variety of immune-mediated conditions such as IMHA, systemic & cutaneous reactive histiocytosis, granulomatous meningoencephalitis, etc.; can be used as part of transplant rejection protocols in dogs. Has been used with methotrexate to treat rheumatoid arthritis in cats.
- ▶ Appears well-tolerated in dogs, but number treated is low
- ▶ Teratogenic (Category X)
- ▶ Active metabolite can persist in body for years
- ▶ Treatment can be very expensive

Uses/Indications

Leflunomide is an immunomodulating drug that may be useful in dogs for treating a variety of immune-related conditions such as IMHA, systemic and cutaneous reactive histiocytosis, granulomatous meningoencephalitis, etc; it can be used as part of transplant rejection protocols in dogs.

Leflunomide has been used with methotrexate to treat rheumatoid arthritis in cats.

Pharmacology/Actions

Leflunomide inhibits autoimmune T-cell proliferation and autoantibody production by B cells. Leflunomide acts almost exclusively via its active metabolite A77 1726 (M1). This metabolite reversibly inhibits the mitochondrial enzyme dihydroorotate dehydrogenase thereby preventing the formation of ribonucleotide uridine monophosphate (rUMP). This causes decreased DNA and RNA synthesis, inhibition of cell proliferation, and G1 cell cycle arrest.

Pharmacokinetics

Information on the pharmacokinetics of leflunomide in dogs and cats was not located. In humans, leflunomide is rapidly converted to A77 1726 (active metabolite; M1) in the GI mucosa and liver. Peak levels of A77 1726 occur between 6–12 hours after an oral dose. The presence of food in the gut does not appear to affect oral bioavailability. A77 1726 is highly bound to albumin (>99%). A77 1726 is further degraded in the liver as glucuronides and an oxalonic acid compound which are excreted in the urine and bile. Half life is about 15 days, but the drug (A77 1726) can be detectable in patients up to 2 years after it is discontinued.

Contraindications/Precautions/Warnings

Leflunomide is contraindicated during pregnancy and in patients hypersensitive to it. It should be used with extreme caution in patients with immunodeficiency.

Adverse Effects

Leflunomide appears to be well tolerated by dogs. Adverse effects reported include vomiting, lymphopenia, and anemia.

In humans, gastrointestinal effects (diarrhea, nausea), alopecia and rash are most commonly reported. Serious adverse effects that have been reported include hematologic toxicity, dermatologic effects (TEN, Stevens-Johnson, etc.), and hepatotoxicity.

Reproductive/Nursing Safety

Leflunomide should not be used during pregnancy. A variety of teratogenic effects in laboratory animals have been detailed at doses used clinically. In humans, the FDA categorizes this drug as category X for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*)

It is not known whether leflunomide is excreted in milk; it is suggested to use milk replacer if the dam is receiving the drug.

Overdosage/Acute Toxicity

Acute toxicologic studies in mice and rats have demonstrated that the minimally toxic dose is 200 mg/kg and 100 mg/kg, respectively. Cholestyramine or activated charcoal are recommended to accelerate elimination. Contact an animal poison control center for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving leflunomide and may be of significance in veterinary patients:

- **CHARCOAL, ACTIVATED:** Can increase elimination and decrease A77 1726 drug concentrations; may be used when more rapid elimination is desirable
- **CHOLESTYRAMINE:** Can increase elimination and decrease A77 1726 drug concentrations; may be used when more rapid elimination is desirable
- **HEPATOTOXIC AGENTS, OTHER:** Increased risk for toxicity
- **METHOTREXATE:** Increased adverse effects and ALT possible
- **PHENYTOIN:** Leflunomide can increase phenytoin levels
- **RIFAMPIN:** Can increase A77 1726 peak levels
- **VACCINES, LIVE VIRUS:** Live virus vaccines should be used with caution, if at all, during leflunomide therapy
- **WARFARIN:** Leflunomide may increase INR

Doses

- **DOGS:**
 - a) As an immunosuppressive as part of a protocol (with cyclosporine) following organ transplant: Leflunomide 4–6 mg/kg PO q24h and then to maintain trough plasma levels of 20 mcg/mL. (Sykes 2007)
 - b) As an adjunctive immunosuppressive for immune-mediated hemolytic anemia: 4 mg/kg PO q24h. (Chabanne 2006)
 - c) For treatment of systemic and cutaneous reactive histiocytosis: 2–4 mg/kg PO once daily to attain trough levels of 20 mcg/mL. (Foil 2003a)
- **CATS:**
 - a) For rheumatoid arthritis: Initially, leflunomide at 10 mg (total dose) PO once daily and methotrexate at 2.5 mg (total dose) PO three times on one day per week. When significant improvement occurs, reduce doses of leflunomide to 10 mg PO twice weekly and methotrexate to 2.5 mg PO once weekly. (Bennett 2005)

Monitoring

- Adverse effects (CBC, liver enzymes)
- Trough levels (20 mcg/mL is target)

Client Information

- Relatively experimental when used in veterinary patients; contact veterinarian if any unusual effects are noted
- Treatment can be very expensive

Chemistry/Synonyms

Leflunomide has a molecular weight of 270.207 g/mol and a melting point of 165–166°C. It is poorly soluble in water (21 mg/L). Leflunomide may also be known as HWA 486, RS 34821, or SU 101; a common trade name is *Arava*®.

Storage/Stability

Leflunomide tablets should be stored at room temperature (15–30°C) and protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Leflunomide Tablets: 10 mg & 20 mg: *Arava*® (Hoechst Marion Roussel); generic; (Rx)

LEUCOVORIN CALCIUM

(loo-koe-vor-in) Folinic Acid, Citrovorum Factor

ORAL OR INJECTABLE FOLIC ACID DERIVATIVE

Prescriber Highlights

- ▶ Primarily used in veterinary medicine to help reverse neurotoxicity or hematologic toxicity associated with dihydrofolate reductase inhibitors (e.g., pyrimethamine, trimethoprim, or ormetoprim)
- ▶ Leucovorin does not require conversion by dihydrofolate reductase for it to be active

Uses/Indications

Leucovorin calcium is the calcium salt of folinic acid and is used as an antidote for toxicity from folic acid antagonists (e.g., methotrexate, pyrimethamine, trimethoprim, ormetoprim). It is used routinely in human medicine as a rescue agent for high-dose methotrexate chemotherapy, but the drug is rarely used for this in veterinary medicine. More commonly, it is used in dogs, cats or horses to help reverse or prevent hematologic toxicity associated with pyrimethamine, trimethoprim, or ormetoprim.

Pharmacology/Actions

Reduced folates act as coenzymes in the synthesis of purine and pyrimidine nucleotides that are necessary for DNA synthesis. Folates are also required for maintenance of normal erythropoiesis.

Leucovorin is a reduced form of folic acid that does not require dihydrofolate reductase conversion, as does folic acid, for it to become biologically active. It is further converted to active reduced forms, of which 5-methyltetrahydrofolate (5-methyl THF) is predominantly responsible for its activity. Although, leucovorin is a mixture of diastereoisomers, only the (-)-L-isomer (citrovorum factor) becomes biologically active.

Leucovorin inhibits thymidylate synthase by stabilizing the binding of fluorodeoxyuridylic acid to the enzyme. This can potentiate the activity, but also the toxicity of fluorouracil (5-FU).

Pharmacokinetics

There is limited information available on the pharmacokinetics of leucovorin in animals. In dogs, the elimination half-life of the L-isomer (active) of leucovorin is about 50 minutes. It is extensively metabolized and then excreted into the urine. The D-form (not biologically active) elimination half-life is about 2.5 hours. Apparent volume of distribution for both forms is about 0.6 L/kg.

In humans, oral bioavailability of leucovorin is reduced as dosage is increased above 25 mg. A 25 mg dose in an adult has a bioavailability of 97%, while 50 mg and 100 mg doses have bioavailabilities of 75% and 37%, respectively. IM bioavailability is similar to IV. Oral doses of 25 mg yield peak levels of leucovorin in about an hour and peaks of the active reduced folates occur between 1.7 and 2.4 hours after dosing. After intravenous administration, peak total reduced folate levels occur in about 10 minutes. About 50% of oral body stores of reduced folates are found in the liver. Elimination occurs in the urine, primarily as 10-formyl-THF or 5,10-methyl-THF. Elimination half-life is approximately 5–6 hours for total reduced folates.

Contraindications/Precautions/Warnings

Leucovorin is contraindicated only when known intolerance to the drug is documented. In humans, cobalamin (B-12) levels may be reduced with megaloblastic anemias and folinic acid therapy may mask the signs associated with it.

Use with extreme caution in patients receiving systemic fluorouracil (see Drug Interactions).

Because of its calcium content, large intravenous doses should be given slowly and not bolused.

Reproductive/Nursing Safety

Leucovorin reproductive studies have not been performed nor is it known if it enters milk, however, it is likely safe to administer during pregnancy or nursing.

Adverse Effects

Adverse effects have not been noted when leucovorin has been used in animals. In humans, gastrointestinal effects can be seen when the drug is given orally and, very rarely, seizures or hypersensitivity reactions may occur.

Overdosage/Acute Toxicity

Except in situations where drug interactions are possible, an inadvertent overdose is unlikely to be of concern.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving leucovorin and may be of significance in veterinary patients:

- **BARBITURATES, PRIMIDONE, PHENYTOIN:** Large doses of leucovorin may reduce the antiseizure efficacy of these agents
- **FLUOROURACIL:** Leucovorin may increase both the antineoplastic efficacy and toxicity of 5-FU
- **TRIMETHOPRIM, ORMETOPRIM, PYRIMETHAMINE** (drugs that inhibit dihydrofolate reductase): Leucovorin may reduce efficacy somewhat, however, protozoa cannot utilize leucovorin

Laboratory Considerations

No specific concerns were noted

Doses**■ DOGS/CATS:**

- a) For folate deficiency associated with pyrimethamine use: 5–15 mg (total dose) PO or parenterally once daily. (Greene, Hartmann et al. 2006)
- b) Cats: For bone marrow suppression associated with pyrimethamine or trimethoprim/sulfa: 5 mg (route not specified) once daily. (Lindsay 2004)
- c) Cats: To prevent bone marrow toxicity associated with pyrimethamine: 1 mg/kg (route not specified) once daily. (Inzana 2002)

- d) For methotrexate overdose: Most effective if given within 48 hours of overdose. The dose of leucovorin is dependent on the serum methotrexate concentration. Dogs with serum methotrexate levels greater than 10^{-7} M at 48 hours have toxic reactions. Leucovorin dosage ranges from 25–200 mg/m² parenterally every 6 hours until methotrexate levels are less than 1×10^{-8} M. In one study, dogs tolerated methotrexate dosages up to 3 g/m² when leucovorin was given at 15 mg/m² IV q 3 hours for 8 doses, then IM q6h hours for 8 doses. Higher doses of methotrexate may be tolerated if higher doses of leucovorin are given. (O'Keefe and Harris 1990)

■ HORSES:

- a) For macrocytic anemia and neutropenia associated with pyrimethamine and/or trimethoprim (especially in pregnant mares): 0.1–0.3 mg/kg PO once daily. A more practical approach would be to ensure that the horse receives green hay or pasture (high tetrahydrofolate levels in green roughage) (Divers 2002)

Monitoring

- CBC
- Methotrexate serum levels (contact a local human hospital) if used for methotrexate overdoses

Client Information

- If being used for methotrexate toxicity, this medication should only be administered in an inpatient setting
- Oral leucovorin may be administered with or without meals.
- Stress adherence to dosage schedule in order to adequately treat or prevent hematologic toxicity

Chemistry/Synonyms

Leucovorin calcium occurs as a yellowish-white or yellow, odorless powder. It is very soluble in water and practically insoluble in alcohol. It is a mixture of diastereoisomers of 5-formyl tetrahydrofolic acid.

Leucovorin calcium may also be known as: folinic acid, citrovorum factor, 5-formyl tetrahydrofolate, citrovorin, folidan, folinic, FTHF, NSC-3590, calcium folinate, calcifolin, calfonat, or folinic acid calcium salt; many international trade names are available.

Storage/Stability/Compatibility

Leucovorin calcium tablets should be stored below 40°C, preferably between 15–30°C in a well-closed container; protect from light. Leucovorin solution for injection should be stored refrigerated between 2°–8°C; protect from light.

Leucovorin Powder for reconstitution and injection should be stored below 40°C, preferably between 15–30°C; protect from light.

The powder for injection is reconstituted by adding 5 or 10 mL of bacteriostatic water for injection or sterile water for injection. As bacteriostatic water for injection contains benzyl alcohol, it is not recommended in neonates or very small animals. If reconstituting with sterile water for injection, the resulting solution should be administered immediately; solutions made with bacteriostatic water for injection are stable for up to 7 days.

Intravenous solutions containing leucovorin calcium in Ringer's lactate, Ringer's, or 0.9% sodium chloride are stable for up to 24 hours at room temperature. Leucovorin calcium is **not compatible** with solutions containing fluorouracil.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Note: Strengths listed are in terms of leucovorin base.

Leucovorin Calcium Tablets: 5 mg, 15 mg, & 25 mg; generic; (Rx)

Leucovorin Calcium Injection: 3 mg/mL in 1 mL amps, & 5 mg/0.5 mL single dose vials; generic; (Rx)

Leucovorin Calcium Powder for Injection: 50 mg, 100 mg, & 350 mg vials; generic; (Rx)

LEUPROLIDE

(loo-*proe*-lide) Lupron®

HORMONAL AGONIST

Prescriber Highlights

- For medical treatment of adrenal associated endocrinopathy in ferrets, & to treat inappropriate egg laying in captive birds
- Depot form must not be confused with once a day injectable, doses below are for depot (IM suspension)
- Teratogenic, contraindicated in pregnancy
- Extremely costly (especially for ferrets); may be obtained in smaller aliquots from compounding pharmacies
- Lab considerations

Uses/Indications

The primary uses for leuprolide at present are for the medical treatment of adrenal associated endocrinopathy in ferrets, and to treat inappropriate egg laying in captive cockatiels. In ferrets, it may be more effective in treating clinical signs associated with adrenal hyperplasia or adenomas than with adenocarcinomas.

Pharmacology/Actions

Leuprolide is a luteinizing hormone-releasing hormone agonist. Via negative feedback, leuprolide inhibits the release of luteinizing hormone and follicle stimulating hormone from the pituitary. Both estrogen and androgen levels are decreased in the serum.

Pharmacokinetics

No veterinary data was located. The depot forms appear to have sustained effects in birds and ferrets.

Contraindications/Precautions/Warnings

Contraindicated in pregnancy.

Adverse Effects

In ferrets, adverse effects reported include pain/irritation at injection site, dyspnea, and lethargy. Tachyphylaxis (higher dosages required over time to obtain same effect) has been reported when using leuprolide in ferrets.

Little information is available on the adverse effect profile of leuprolide birds. At this point, it appears safe at the recommended doses.

Reproductive/Nursing Safety

Leuprolide is considered contraindicated in pregnancy. Major fetal abnormalities may result. In humans, the FDA categorizes this drug as category **X** for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports in-*

dicade evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.)

It is not known whether leuprolide is excreted in milk; use with caution.

Overdosage/Acute Toxicity

Because of its expense and method of dosing, it is unlikely an acute overdose would occur. Studies in lab animals at dosages of up to 5 gm/kg IM produced no untoward effects.

Drug Interactions

No documented adverse drug interactions with leuprolide were located.

Laboratory Considerations

- Diagnostic tests measuring **pituitary gonadotrophic** and **gonadal functions** may be misleading during, and for several months after discontinuing therapy

Doses

■ FERRETS:

For treatment of adrenal associated endocrinopathy:

- Using the depot form: 100 mcg IM once a month (Wagner, Bailey et al. 2001)
- Using the 4 month depot form: 2 mg IM for a 3 lb ferret; may last 5–6 months. Not as effective with carcinomas. (Weiss 2002a)
- Using the 30 day depot form: If ferret weighs less than 1 kg: 100 mcg IM q30 days. If weighs >1 kg: 200 mcg IM q30 days. Generally, the drug is diluted from its original concentration to negate the muscle necrosis problem that has been reported. The diluted form appears to remain active after being stored in the freezer for a year. (Murray 2002) (**Note:** The manufacturer states that the depot form is not to be frozen and no studies are known that support the stability of the depot activity when frozen and thawed—Plumb)
- Using the one month depot form: 100–250 mcg/kg IM every 4 weeks until signs resolve, then every 4–8 weeks as needed, lifelong. Larger ferrets may require the higher dosage range. (Johnson 2006b)

■ BIRDS:

To inhibit egg laying in pet birds:

- For inappropriate egg laying (to reduce or prevent ovulation) in Cockatiels using Lupron Depot: 0.375 mg per Cockatiel IM once monthly (Tully 2000)
- 100 mcg/kg per day. Multiply dose by number of days for effect and give once monthly. Example: 100 mcg/kg for 28 days = 2800 mcg/kg dose (Olsen and Orosz 2000)

Monitoring

- Clinical effects (Birds: decreased egg-laying; Ferrets: decreases in vulvar swelling, pruritus, undesirable sexual behaviors, aggression, and increased hair regrowth)

Client Information

- Relatively experimental in birds or ferrets. Long-term safety is not known.
- Can be extremely expensive to treat.

Chemistry/Synonyms

A synthetic nonapeptide analog of GnRH (gonadotropin releasing hormone, gonadorelin, luteinizing hormone-releasing hormone), leuprolide acetate occurs as a white to off-white powder. In water more than 250 mg are soluble in one mL.

Leuprolide may also be known as: leuprorelin, leuprorelinum, abbot-43818, leuprolide acetate, TAP-144, *Carcinil*®, *Daronda*®, *Eligard*®, *Elityran*®, *Enanton*®, *Enantone*®, *Enantone-Gyn*®, *Ginecrin*®, *Lectrum*®, *Leuplin*®, *Lucrin*®, *Lupride*®, *Lupron*®, *Procren*®, *Procrin*®, *Prostap*®, *Reliser*®, *Trenantone*®, *Uno-Enantone*®, and *Viadur*®.

Storage/Stability/Compatibility

The injection should be stored below room temperature (<78°F); do not freeze and protect from light (store in carton until use). The depot form may be stored at room temperature. After reconstituting the suspension is stable for 24 hours, but as it contains no preservative it is recommended for immediate use.

The manufacturer states that the depot form is not to be frozen and no studies are known that support the stability of the depot activity when frozen and thawed.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Leuprolide Acetate Injection: 5 mg/mL in 2.8 mL multi-dose vials; *Lupron*® & *Lupron*® for Pediatric Use (TAP Pharm); generic; (Rx)

Leuprolide Acetate Injection: 22.5 mg in single-use kits with a 2-syringe mixing system and needle; 30 mg & 45 mg in single-use kit with 2-syringe mixing system and syringe containing *Atrigel*; *Eligard*® (Sanofi-Synthelabo); (Rx)

Leuprolide Powder for Injection: lyophilized 7.5 mg in single-use kits with a 2-syringe mixing system and needle; *Eligard*® (Sanofi-Synthelabo); (Rx)

Leuprolide Acetate Microspheres for Injection, lyophilized and preservative free with mannitol: 3.75 mg, 7.5 mg, 11.25 mg, 15 mg single dose kits and pre-filled dual-chamber syringes; *Lupron*® Depot and *Lupron*® Depot-Ped (TAP Pharm); (Rx)

Leuprolide Acetate Microspheres for Injection, lyophilized and preservative free with mannitol: 11.25 mg and 22.5 mg (3 month), 30 mg (4 month) in single pre-filled dual-chamber syringes; *Lupron*® Depot-3 or -4 Month, (TAP Pharm); (Rx)

Leuprolide Acetate Implants: 72 mg in single-dose kit; *Viadur*® (ALZA Corporation); (Rx)

LEVAMISOLE

(*leh-vam-i-sole*) Levasole®, Tramisol®

ANTIPARASITIC, IMMUNE STIMULANT

Prescriber Highlights

- Antinematodal parasiticide that also may be useful as an immune stimulant
- Contraindications: Milk-producing animals (not approved)
- Very cautiously, if at all: Severely debilitated, or significant renal or hepatic impairment; in cattle that are stressed due to vaccination, dehorning, or castration
- Not usually used in horses; infrequently used in small animals today as an antiparasitic agent
- Numerous adverse effects

Uses/Indications

Depending on the product licensed, levamisole is indicated for the treatment of many nematodes in cattle, sheep and goats, swine, poultry. In sheep and cattle, levamisole has relatively good activity against abomasal nematodes, small intestinal nematodes (not particularly good against *Strongyloides* spp.), large intestinal nematodes (not *Trichuris* spp.), and lungworms. Adult forms of species that are usually covered by levamisole, include: *Haemonchus* spp., *Trichostrongylus* spp., *Ostertagia* spp., *Cooperia* spp., *Nematodirus* spp., *Bunostomum* spp., *Oesophagostomum* spp., *Chabertia* spp., and *Dictyocaulus vivapurus*. Levamisole is less effective against the immature forms of these parasites, and is generally ineffective in cattle (but not sheep) against arrested larval forms. Resistance of parasites to levamisole is a growing concern.

In swine, levamisole is indicated for the treatment of *Ascaris suum*, *Oesophagostomum* spp., *Strongyloides*, *Stephanurus*, and *Metastrongylus*.

Levamisole has been used in dogs as a microfilaricide to treat *Dirofilaria immitis* infection in the past, but is rarely used today. It has also garnered some interest as an immunostimulant in the adjunctive therapy of various neoplasms.

Because of its narrow margin for safety and limited efficacy against many equine parasites, levamisole is not generally used in horses as an antiparasitic agent. It has been tried as an immune stimulant, however.

Pharmacology/Actions

Levamisole stimulates the parasympathetic and sympathetic ganglia in susceptible worms. At higher levels, levamisole interferes with nematode carbohydrate metabolism by blocking fumarate reduction and succinate oxidation. The net effect is a paralyzing effect on the worm that is then expelled alive. Levamisole's effects are considered to be nicotine-like in action.

Levamisole's mechanism of action for its immunostimulating effects are not well understood. It is believed it restores cell-mediated immune function in peripheral T-lymphocytes and stimulates phagocytosis by monocytes. Its immune stimulating effects appear to be more pronounced in animals that are immune-compromised.

Pharmacokinetics

Levamisole is absorbed from the gut after oral dosing and through the skin after dermal application, although bioavailabilities are variable. It is reportedly distributed throughout the body. Levamisole is primarily metabolized with less than 6% excreted unchanged in the urine. Plasma elimination half-lives have been determined for several veterinary species: Cattle, 4–6 hours; Dogs, 1.8–4 hours; and Swine, 3.5–6.8 hours. Metabolites are excreted in both the urine (primarily) and feces.

Contraindications/Precautions/Warnings

Levamisole is contraindicated in lactating animals (not approved). It should be used cautiously, if at all, in animals that are severely debilitated, or significant renal or hepatic impairment.

Use cautiously or, preferably, delay use in cattle that are stressed due to vaccination, dehorning, or castration.

Levamisole is not indicated for use as a dirofilarial adulticide.

Avoid, if possible, administering levamisole intramuscularly to birds.

Adverse Effects

Adverse effects that may be seen in cattle can include muzzle foaming or hypersalivation, excitement or trembling, lip-licking and head shaking. These effects are generally noted with higher than recommended doses or if levamisole is used concomitantly with organophosphates. Signs generally subside within 2 hours. When

injecting into cattle, swelling may occur at the injection site. This will usually abate in 7–14 days, but may be objectionable in animals that are close to slaughter.

In sheep, levamisole may cause a transient excitability in some animals after dosing. In goats, levamisole may cause depression, hyperesthesia, and salivation. Injecting levamisole SC in goats apparently causes a stinging sensation.

In swine, levamisole may cause salivation or muzzle foaming. Swine infected with lungworms may develop coughing or vomiting.

Adverse effects that may be seen in dogs include GI disturbances (usually vomiting, diarrhea), neurotoxicity (panting, shaking, agitation or other behavioral changes), immune-mediated anemia, agranulocytosis, dyspnea, pulmonary edema, immune-mediated skin eruptions (erythroedema, erythema multiforme, toxic epidermal necrolysis), and lethargy.

Adverse effects seen in cats include hypersalivation, excitement, mydriasis, and vomiting.

Reproductive/Nursing Safety

There is little information available regarding the safety of this drug in pregnant animals. Although levamisole is considered relatively safe to use in large animals that are pregnant, use only if the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: C (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Levamisole is excreted in cows' milk; use with caution in nursing dams.

Overdosage/Toxicity

Signs of levamisole toxicity often mimic those of organophosphate toxicity. Signs may include hypersalivation, hyperesthesias and irritability, clonic seizures, CNS depression, dyspnea, defecation, urination, and collapse. These effects are best treated by supportive means as animals generally recover within hours of dosing. Acute levamisole overdosage can result in death due to respiratory failure. Should respiratory failure occur, artificial ventilation with oxygen should be instituted until recovery occurs. Cardiac arrhythmias may also be seen. If the ingestion was oral, emptying the gut and/or administering charcoal with cathartics may be indicated.

Levamisole is considered to be more dangerous when administered parenterally than when given orally or topically. Intravenous administration is particularly hazardous, and is never recommended.

In pet birds (cockatoos, budgerigars, Mynah birds, parrots, etc.), 40 mg/kg has been reported as a toxic dose when administered SC. IM injections may cause more severe toxicity. Depression, ataxia, leg and wing paralysis, mydriasis, regurgitation, and death may be seen after a toxic dose in birds.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving levamisole and may be of significance in veterinary patients:

- **ASPIRIN:** Levamisole may increase salicylate levels
- **CHLORAMPHENICOL:** Fatalities have been reported after concomitant levamisole and chloramphenicol administration; avoid using these agents together

■ **CHOLINESTERASE-INHIBITING DRUGS** (e.g., organophosphates, neostigmine): Could theoretically enhance the toxic effects of levamisole; use together with caution

■ **NICOTINE-LIKE COMPOUNDS** (e.g., pyrantel, morantel, diethylcarbamazine): Could theoretically enhance the toxic effects of levamisole; use together with caution.

■ **WARFARIN**: Increased risk for bleeding

Doses

■ DOGS:

As an immune stimulant:

- For recurrent cutaneous infections: 2.2 mg/kg PO every other day, with appropriate antimicrobial therapy (Rosenkrantz 1989)
- 0.5–2 mg/kg PO 3 times a week (Kirk 1989)
- For adjunctive therapy in dogs with chronic pyoderma: 0.5–1.5 mg/kg PO 2–3 times a week (efficacy not established) (Lorenz 1984)
- For adjunctive therapy in dogs with chronic pyoderma: 2.2 mg/kg PO every other day (may only be efficacious in 10% of cases) (Ihrke 1986)
- For adjunctive therapy in aspergillosis/penicillinosis: 2–5 mg/kg PO every other day (Prueter 1988)

As an alternative treatment for SLE:

- 3–7 mg/kg PO every other day for 4 months; alone or in combination with corticosteroids (Marks and Henry 2000)

As a microfilaricide (**Note**: Rarely recommended today):

- 11 mg/kg PO for 6–12 days. Examine blood on 6th day of treatment; discontinue therapy when microfilaria negative. May cause neurologic signs, vomiting, behavioral changes, or possibly death. If treatment is prolonged (>15 days), there is increased likelihood of toxicity. (Todd, Paul, DiPietro 1985)
- 11 mg/kg PO for 6–12 days. Examine for microfilaria within 7–10 days and at weekly intervals until eliminated or treatment is halted. Retching and vomiting are common. Avoid giving on an empty stomach or immediately after drinking water. A “conditioning” dose of 5 mg/kg PO once a day may be necessary. Stop therapy if abnormal behavior or ataxia develops. (Knight 1988)

For treatment of *Angiostrongylus vasorum*:

- 7.5 mg/kg (route not specified) for two consecutive days, followed by 10 mg/kg for 2 days; if the infection is not cleared, the regimen is repeated. (Bowman 2006a)

For the treatment of lungworms:

- For *Crenosoma vulpis*: 8 mg/kg once (Todd, Paul, and DiPietro 1985)
- For *Capillaria*: 7–12 mg/kg once daily PO for 3–7 days
For *Filaroides osleri*: 7–12 mg/kg once daily PO for 20–45 days (Roudebush 1985)
- 7.5 mg/kg PO twice daily or 25 mg/kg PO every other day for 10 days (Bauer 1988)
- For *Capillaria aerophila*: 10 mg/kg PO once daily for 5 days; repeat in 9 days (Reinemeyer 1995)

■ CATS:

For the treatment of lungworms:

- 20–40 mg/kg PO every other day for 5–6 treatments (Kirk 1989)
- For *Aelurostrongylus abstrusus*: 100 mg PO daily every other day for 5 treatments; give atropine (0.5 mg SC, 15 minutes before administering); or 15 mg/kg PO every other day for 3 treatments, then 3 days later: 30 mg/kg PO, then 2 days later: 60 mg/kg.

For *Capillaria aerophila*: 4.4 mg/kg SC for 2 days, then 8.8 mg/kg once 2 weeks later; or 5 mg/kg PO once daily for 5 days, followed by 9 days of no therapy, repeat two times (Todd, Paul, and DiPietro 1985)

- 25 mg/kg every other day for 10–14 days (Roudebush 1985)
- For *Capillaria aerophila*: 10 mg/kg PO once daily for 5 days; repeat in 9 days (Reinemeyer 1995)

For treatment of *Ollulanus tricuspis*:

- 5 mg/kg SC (Todd, Paul, and DiPietro 1985)

As a microfilaricide:

- 10 mg/kg PO for 7 days (Dillon 1986)

As an immune-stimulant:

- For adjunctive therapy of feline plasma-cell gingivitis/pharyngitis: 25 mg PO every other day for 3 doses (DeNovo, Potter, and Woolfson 1988)

■ RABBITS/RODENTS/SMALL MAMMALS:

- Rabbits: For nematodes: 12.5–20 mg/kg PO (for gastric nematodes) or SC (for extragastric nematodes) (Ivey and Morrissey 2000)

■ HORSES:

As an immunostimulant:

- Dosages have ranged from 2.5 mg/kg injected at 7 day intervals, and 2.2 mg/kg PO every 24 hours for 3 days, then off for 4 days for a period of 4–6 weeks. Anecdotal reports of beneficial effects in the treatment of nasal viral papillomas, COPD, and EPM have been suggested. (Bentz 2006a)

■ CATTLE:

For treatment of susceptible nematodes (also refer to specific label directions for approved products):

- For removal of mature and immature *Dictyocaulus vivaparus*: 5.5–11 mg/kg PO, either given in feed or as a drench or oral bolus. May also be administered SC at 3.3–8 mg/kg. (Bennett 1986)
- 7.5 mg/kg PO (Brander, Pugh, and Bywater 1982)

■ LLAMAS:

For treatment of susceptible nematodes:

- 5–8 mg/kg IM, or PO (Fowler 1989)
- 5–8 mg/kg PO or SC for 1 day (Cheney and Allen 1989)

■ SWINE:

For treatment of susceptible nematodes (also refer to specific label directions for approved products):

- For removal of mature and immature *Metastrongylus*: 8 mg/kg PO in feed or water (Bennett 1986)
- 8 mg/kg PO in feed or water (Howard 1986)
- 7.5 mg/kg PO (Brander, Pugh, and Bywater 1982)

■ SHEEP & GOATS:

For treatment of susceptible nematodes (also refer to specific label directions for approved products):

- For removal of mature and immature *Dictyocaulus vivaparus*: 8 mg/kg PO (Bennett 1986)
- 7.5 mg/kg PO (Brander, Pugh, and Bywater 1982)

■ BIRDS:

- Using 13.65% injectable:

For intestinal nematodes: 5–15 mL/gallon of drinking water for 1–3 days; repeat in 10 days. If birds refuse to drink, withhold water prior to treating.

For gavage in Australian Parakeets (or desert species that refuse to drink water): 15 mg/kg; repeat in 10 days

For parenteral use: 4–8 mg/kg IM or SC; repeat in 10–14 days. May cause vomiting, ataxia, or death. Do not use in debilitated birds.

For immunostimulation: 0.3 mL/gallon of water for several weeks

As a parenteral immunostimulant: 2 mg/kg IM or SC. 3 doses at 14 day intervals (Clubb 1986)

- b) As a nebulized immunostimulant: 1 mL (of 13.65% levamisole phosphate) in 15 mL saline (Spink 1986)
- c) For *Capillaria* infections: 15–30 mg/kg orally as a single bolus or through a crop tube; or 2.25 mg/gallon of drinking water for 4–5 days. Repeat treatment in 10–14 days. (Flammer 1986)
- d) Poultry: 18–36 mg/kg, PO (Brander, Pugh, and Bywater 1982)
- e) Ratites: For *Libyastrongylus douglassi*: Give 30 mg/kg PO or IM at one month of age, then once a month for 7 treatments, then 4 times yearly (Jenson 1998)

Monitoring

- Clinical efficacy
- Adverse effects/toxicity observation

Client Information

- Levamisole is not approved for use in dairy animals of breeding age.
- Follow directions on the product label unless otherwise directed by veterinarian. Animals that are severely parasitized or in conditions with constant helminth exposure should be retreated 2–4 weeks after initial treatment.
- Do not administer injectable products IV.
- Report serious adverse effects to veterinarian.

Chemistry/Synonyms

The levo-isomer of dl-tetramisole, levamisole has a greater safety margin than does the racemic mixture. It is available commercially in two salts, a phosphate and a hydrochloride. Levamisole hydrochloride occurs as a white to pale cream colored, odorless or nearly odorless, crystalline powder. One gram is soluble in 2 mL of water.

Levamisole HCl may also be known as: cloridrato de levamizol, ICI-59623, levamisoli hydrochloridum, NSC-177023, R-12564, RP-20605, l-tetramisole hydrochloride, *Amtech*®, *Ascaridil*®, *Decaris*®, *Ergamisol*®, *Immunol*®, *Ketrax*®, *Levasole*®, *Meglum*®, *Prohibit*®, *Solaskil*®, *Vermisol*®, and *Vizole*®.

Storage/Stability/Compatibility

Levamisole hydrochloride products should be stored at room temperature (15–30°C), unless otherwise instructed by the manufacturer; avoid temperatures greater than 40°C. Levamisole phosphate injection should be stored at temperatures at or below 21°C (70°F); refrigeration is recommended and freezing should be avoided.

Levamisole tablets should not be crushed nor suspensions made from them.

Dosage Forms/Regulatory Status/Withdrawal Times

In cattle, sheep, and swine a level of 0.1 ppm has been established for negligible residues in edible tissues.

VETERINARY-LABELED PRODUCTS:

Levamisole Phosphate Injection: 136.5 mg/mL (13.65%) in 500 mL vials. Levamisole Injectable (AgriLabs), *Levasole*® *Injectable Solution* 13.65% (Schering Plough); Approved for use in cattle. Slaughter withdrawal (at labeled dosages) = 7 days. To prevent residues in milk, do not administer to dairy animals of breeding age.

Levamisole Hydrochloride Water Medication: 18.15 g in 0.71 oz bottle. *Levamisole Soluble Pig Wormer* (AgriLabs, Durvet, Aspen); (OTC); *Levasole*® *Soluble Pig Wormer* (Schering-Plough), *Amtech*® *Levamisole HCl Pig Wormer* (IVX); (OTC). Approved for use in swine. Slaughter withdrawal (at labeled dosages) = 72 hours

Levamisole Hydrochloride Anthelmintic Oral: *Levasole*® *Soluble Drench Powder* 46.8 grams/packet (Schering-Plough); (OTC). Approved for use in cattle (Not in dairy animals of breeding age), and sheep. Slaughter withdrawal (at labeled dosages) = 48 hours (cattle); 72 hours (sheep)

Levamisole Hydrochloride Soluble Drench Powder 46.8 grams/packet; 544.5 g/21.34 oz bottle. *Prohibit*® (AgriLabs) (OTC). Approved for use in cattle and sheep. Slaughter withdrawal (at labeled dosages) cattle = 48 hours, sheep = 72 hours. To prevent residues in milk, do not administer to dairy animals of breeding age.

Levamisole HCl Oral Tablets/Boluses: 184 mg bolus: *Levasole*® *Sheep Wormer Bolus* (Schering Plough); (OTC). Approved for use in sheep. Slaughter withdrawal (at labeled dosages) = 72 hours.

Levamisole 2.19 gram bolus: *Levasole*® *Cattle Wormer Boluses* (Schering-Plough); (OTC). Approved for use in beef (not for use in dairy animals of breeding age). Slaughter withdrawal (at labeled dosages) = 48 hours.

HUMAN-LABELED PRODUCTS:

Levamisole HCl Tablets: 50 mg levamisole base; *Ergamisol*® (Janssen); (Rx)

LEVETIRACETAM

(lee-ve-tye-ra-se-tam) Keppra®

ANTICONVULSANT

Prescriber Highlights

- May be useful as a third drug adjunct for refractory canine epilepsy or when either phenobarbital or bromides are not tolerated; may also be useful in cats, but less is known
- Limited clinical experience; investigations ongoing regarding efficacy, adverse effects
- Appears to be well tolerated in dogs & cats
- Not substantially metabolized by liver; does not induce hepatic enzymes
- Dosage frequency (three times daily) problematic; cost may be prohibitive

Uses/Indications

Levetiracetam may be useful as a third antiseizure medication in dogs that are not well controlled with phenobarbital and bromides or when either bromides or phenobarbital are not tolerated. Some evidence suggests that in dogs suffering from phenobarbital liver toxicity, the addition of levetiracetam will allow reduction of their phenobarbital dosage without increasing seizure frequency.

Levetiracetam may also be useful as add-on therapy in cats.

Pharmacology/Actions

The exact mechanism for levetiracetam's antiseizure activity is not well understood. It may selectively prevent hypersynchronization of epileptiform burst-firing and propagation of seizure activity. It does not affect normal neuronal excitability.

Pharmacokinetics

Little published pharmacokinetic data is available for dogs; elimination half-life is about 4 hours and volume of distribution is about 0.5 L/kg. In a very small sample size, levetiracetam half-life in cats was around 5 hours. In humans, levetiracetam is rapidly, and nearly completely, absorbed after oral administration. Peak levels occur about one hour after dosing. Presence of food in the gut delays the rate, but not the extent, of drug absorbed. Less than 10% of the drug is bound to plasma proteins. While not extensively metabolized, the drug's acetamide group is enzymatically hydrolyzed to the carboxylic acid metabolite that is apparently not active. Hepatic CYP P450 isoenzymes are not involved. Half-life in humans is about 7 hours; about 66% of a given dose is excreted unchanged via renal mechanisms, primarily glomerular filtration and active tubular secretion. Clearance can be significantly reduced in patients with impaired renal function.

Contraindications/Precautions/Warnings

Levetiracetam is contraindicated in patients who have previously exhibited hypersensitivity to it or any of its components. It should be used with caution in patients with renal impairment; dosage amounts or dosing frequency changes should be considered. In humans, renal elimination of levetiracetam correlates with creatinine clearance.

Adverse Effects

Levetiracetam appears to be very well tolerated in the limited number of dogs treated thus far. Changes in behavior, somnolence, and gastrointestinal effects could occur.

In cats, the drug appears to have a wide safety margin, but less clinical use has occurred in that species. Transient inappetence has been reported in some cats receiving the drug.

In humans, it is recommended to withdraw the drug slowly to prevent "withdrawal" seizures.

Reproductive/Nursing Safety

In pregnant dogs or cats, levetiracetam should be used with caution. In humans, the FDA categorizes levetiracetam as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). At high dosages, levetiracetam has caused increased embryofetal mortality in rabbits and rats. At dosages equivalent to the maximum human therapeutic dose, levetiracetam caused minor skeletal abnormalities and retarded offspring growth in rats.

Levetiracetam is excreted into maternal milk and its safety in nursing offspring is unknown. Use with caution in nursing patients.

Overdosage/Acute Toxicity

Levetiracetam is a relatively safe agent. Dogs given 1200 mg/kg/day (approximately 20 times therapeutic dosage) developed only salivation and vomiting. Human patients given 6000 mg/kg during drug testing developed only drowsiness. Other effects noted in human overdoses (doses not specified) after the drug was released include depressed levels of consciousness, agitation, aggression and respiratory depression. Treatment is basically supportive; the drug can be removed with hemodialysis. In the circumstance of a significant overdose in animals, contact an animal poison control center for further recommendations.

Drug Interactions

No clinically significant adverse drug interactions were located.

Laboratory Considerations

No specific laboratory interactions or considerations noted.

Doses

■ DOGS:

- As an add-on treatment for epilepsy in dogs refractory to phenobarbital and bromides: 20 mg/kg PO every 8 hours (Munana 2004b)
- As an add-on treatment for epilepsy in dogs refractory to phenobarbital and/or bromides: 7.1–23.8 mg/kg PO every 8 hours (Steinberg and Faissler 2004)
- 10–20 mg/kg PO q8h (Dickinson 2007)
- 10–20 mg/kg PO q8–12h (Podell 2006a)
- Initially, 20 mg/kg PO q8h. May increase dose in 20 mg/kg increments until efficacy achieved, side effects become apparent, or the drug becomes cost prohibitive. (Dewey 2005a)

■ CATS:

- As an add-on to phenobarbital treatment for epilepsy: Initially, 20 mg/kg PO three times daily; slowly increase to effect (Pearce 2006b)

Monitoring

- At this point, in both humans and dogs, blood levels of levetiracetam are not monitored for either efficacy or toxicity.
- Veterinarians should have the owner keep a record of seizure activity to document efficacy and report any potential levetiracetam-associated adverse effects.

Client Information

- Clients should understand that limited experience has occurred with levetiracetam in dogs. Although it appears to be well tolerated, information on its safety and efficacy profile is still being generated.
- The current dosage frequency recommendation (q8h) may be difficult to adhere to, but the drug may not be effective if not followed.
- The cost of this medication can be very substantial; potentially several hundred dollars per month (depending on dog's size).

Chemistry/Synonyms

A pyrrolidone-derivative antiepileptic agent, levetiracetam occurs as an odorless, bitter-tasting, white to off-white crystalline powder. It is very soluble in water and soluble in ethanol. It is a chiral molecule with one asymmetric carbon atom. Levetiracetam is not related chemically to other antiseizure medications.

Levetiracetam may also be known as: S-Etriacetam, UCB-22059, UCB-L059, and *Keppra*®.

Storage/Stability

Levetiracetam tablets or oral solution should be stored at 25°C (77°F); excursions permitted to 15–30°C (59–86°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Levetiracetam Tablets (film-coated, scored): 250 mg, 500 mg, 750 mg & 1000 mg; *Keppra*® (UCB); (Rx)

Levetiracetam Oral Solution: 100 mg/mL in 480 mL; *Keppra*® (UCB), (Rx)

Levetiracetam Solution for Injection: 100 mg/mL (45 mg sodium chloride & 8.2 mg sodium acetate trihydrate/5 mL) in 5 mL vials; *Keppra*® (UCB Pharma); (Rx)

LEVOTHYROXINE SODIUM

(lee-voe-thye-rox-een) Soloxine®, Synthroid®

THYROID HORMONE

Prescriber Highlights

- ▶ Thyroid hormone for hypothyroidism in all species
- ▶ Contraindications: Acute myocardial infarction, thyrotoxicosis, or untreated adrenal insufficiency
- ▶ Caution: Concurrent hypoadrenocorticism (treated), cardiac disease, diabetes, or elderly patients
- ▶ Adverse Effects: Only associated with OD's (tachycardia, polyphagia, PU/PD, excitability, nervousness, & excessive panting); some cats may appear apathetic
- ▶ Drug-drug; drug-lab interactions

Uses/Indications

Levothyroxine sodium is indicated for the treatment of hypothyroidism in all species.

Pharmacology/Actions

Thyroid hormones affect the rate of many physiologic processes including: fat, protein, and carbohydrate metabolism, increasing protein synthesis, increasing gluconeogenesis, and promoting mobilization and utilization of glycogen stores. Thyroid hormones also increase oxygen consumption, body temperature, heart rate and cardiac output, blood volume, enzyme system activity, and growth and maturity. Thyroid hormone is particularly important for adequate development of the central nervous system. While the exact mechanisms how thyroid hormones exert their effects are not fully understood, it is known that thyroid hormones (primarily triiodothyronine) act at the cellular level.

In humans, triiodothyronine (T₃) is the primary hormone responsible for activity. Approximately 80% of T₃ found in the peripheral tissues is derived from thyroxine (T₄) which is the principle hormone released by the thyroid.

Pharmacokinetics

In dogs, peak plasma concentrations after oral dosing reportedly occur 4–12 hours after administration and the serum half-life is approximately 12–16 hours. There is wide variability from animal to animal, however.

Contraindications/Precautions/Warnings

Levothyroxine (and other replacement thyroid hormones) are contraindicated in patients with acute myocardial infarction, thyrotoxicosis, or untreated adrenal insufficiency. It should be used with caution, and at a lower initial dosage, in patients with concurrent hypoadrenocorticism (treated), cardiac disease, diabetes, or in those who are aged.

Adverse Effects

When administered at an appropriate dose to patients requiring thyroid hormone replacement, there should not be any adverse effects associated with therapy. For adverse effects associated with overdosage, see below.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category A for use during pregnancy (*Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Minimal amounts of thyroid hormones are excreted in milk and should not affect nursing offspring.

Overdosage/Acute Toxicity

Chronic overdosage will produce signs of hyperthyroidism, including tachycardia, polyphagia, PU/PD, excitability, nervousness and excessive panting. Dosage should be reduced and/or temporarily withheld until signs subside. Some (10%?) cats may exhibit signs of "apathetic" (listlessness, anorexia, etc.) hyperthyroidism.

A single acute overdose in small animals is less likely to cause severe thyrotoxicosis than with chronic overdosage. Vomiting, diarrhea, hyperactivity to lethargy, hypertension, tachycardia, tachypnea, dyspnea, and abnormal pupillary light reflexes may be noted in dogs and cats. In dogs, clinical signs may appear within 1–9 hours after ingestion. If ingestion occurred within 2 hours, treatment to reduce absorption of drug should be accomplished using standard protocols (emetics, cathartics, charcoal) unless contraindicated by the patient's condition. Treatment is supportive and symptomatic. Oxygen, artificial ventilation, cardiac glycosides, beta-blockers (e.g., propranolol), fluids, dextrose, and antipyretic agents have all been suggested for use if necessary; contact an animal poison control center for further guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving levothyroxine and may be of significance in veterinary patients:

- **AMIODARONE:** May decrease the metabolism of T₄ to T₃
- **ANTACIDS, ORAL:** May reduce levothyroxine absorption; separate doses by 4 hours
- **ANTIDEPRESSANTS, TRICYCLIC/TETRACYCLIC:** Increased risk for CNS stimulation and cardiac arrhythmias
- **ANTIDIABETIC AGENTS (insulin, oral agents):** Levothyroxine may increase requirements for insulin or oral agents
- **CHOLESTYRAMINE:** May reduce levothyroxine absorption; separate doses by 4 hours
- **CORTICOSTEROIDS (high dose):** Decreased conversion of T₄ to T₃
- **DIGOXIN:** Potential for reduced digoxin levels
- **FERROUS SULFATE:** May reduce levothyroxine absorption; separate doses by 4 hours
- **HIGH FIBER DIET:** May reduce levothyroxine absorption
- **KETAMINE:** May cause tachycardia and hypertension
- **PHENOBARBITAL:** Possible increased metabolism of thyroxine; dosage adjustments may be needed
- **PROPYLTHIOURACIL:** Decreased conversion of T₄ to T₃
- **RIFAMPIN:** Possible increased metabolism of thyroxine; dosage adjustments may be needed
- **SERTRALINE:** May increase levothyroxine requirements
- **SUCRALFATE:** May reduce levothyroxine absorption; separate doses by 4 hours
- **SYMPATHOMIMETIC AGENTS (epinephrine, norepinephrine, etc.):** Levothyroxine can potentiate effects
- **WARFARIN:** Thyroid hormones increase the catabolism of vitamin K-dependent clotting factors that may increase the anticoagulation effects in patients on warfarin

Laboratory Considerations

The following drugs may have effects on thyroid function tests; evaluate results accordingly:

- **EFFECTS ON SERUM T₄:** aminoglutethimide↓, anabolic steroids/androgens↓, antithyroid drugs (PTU, methimazole)↓, asparaginase↓, barbiturates↓, corticosteroids↓, danazol↓, diazepam↓, estrogens↑ (**Note:** estrogens may have no effect on canine T₃ or T₄ concentrations), fluorouracil↑, heparin↓, insulin↑, lithium carbonate↓, mitotane (o,p-DDD)↓, nitroprusside↓, phenylbutazone↓, phenytoin↓, propranolol↑, salicylates (large doses)↓, and sulfonyleureas↓.
- **EFFECTS ON SERUM T₃:** antithyroid drugs (PTU, methimazole)↓, barbiturates↓, corticosteroids↓, estrogens↑, fluorouracil↑, heparin↓, lithium carbonate↓, phenytoin↓, propranolol↓, salicylates (large doses)↓, and thiazides↑.
- **EFFECTS ON T₃ UPTAKE RESIN:** anabolic steroids/androgens↑, antithyroid drugs (PTU, methimazole)↓, asparaginase↑, corticosteroids↑, danazol↑, estrogens↓, fluorouracil↓, heparin↑, lithium carbonate↓, phenylbutazone↑, and salicylates (large doses)↑.
- **EFFECTS ON SERUM TSH:** aminoglutethimide↑, antithyroid drugs (PTU, methimazole)↑, corticosteroids↓, danazol↓, and lithium carbonate↑.
- **EFFECTS ON FREE THYROXINE INDEX (FTI):** antithyroid drugs (PTU, methimazole)↓, barbiturates↓, corticosteroids↓, heparin↑, lithium carbonate↓, and phenylbutazone↓.

Doses

■ DOGS:

For hypothyroidism:

- a) Use a trade name product. Initially give 20 micrograms/kg (0.02 mg/kg) body weight PO twice daily with a maximum dose of 0.8 mg twice daily. Four to eight weeks later evaluate clinical response and draw a T₄ level 4–6 hours post dosing.

If positive clinical response and **1**) low normal T₄: increase dose and recheck in 4 weeks; **2**) high normal to slightly higher than normal T₄: no change in dosing and recheck in 6 months; **3**) 40% or more greater than high normal: decrease dose or consider once a day therapy and recheck in 4 weeks (if once a day dosing get a level prior to dosing as well).

If a negative clinical response and **1**) low normal T₄: increase dose and recheck in 8 weeks (may need to: increase dose again; change to 3 times a day dosing or reevaluate diagnosis); **2**) high normal to 40% or more greater than high normal: re-evaluate diagnosis.

For myxedema coma: 5 mcg/kg IV q12h initially as oral administration may be poorly absorbed (Scott-Moncrieff and Guptill-Yoran 2000)
- b) Initiate treatment at 22 micrograms/kg PO twice daily (0.1 mg/10 lbs body weight twice daily); reevaluate dosage after monitoring clinical response and serum levels after 4–8 weeks. If clinical response is satisfactory and T₄ is elevated (≥ 60 nmol/L) may reduce dosage to 22 micrograms/kg once daily. If clinical response is not satisfactory, either reevaluate the need for T₄ supplementation or increase the dose. Daily dosage of 20–40 micrograms/day appears to be adequate for most dogs. (Refsal and Nachreiner 1995)
- c) 0.022 mg/kg (22 mcg/kg) PO twice daily or 0.044/kg mg (44 mcg/kg) once daily. Monitor by resolution of clinical signs, pre- and post dosing Total T₄ (in the normal range), or by endogenous TSH concentrations that decrease into the normal range. (Greco 1999)

- d) 0.02 mg/kg PO twice daily to start; (0.02–0.04 mg/kg PO once daily or, if necessary divided twice daily to maintain). Alternatively, give 0.5 mg/m² which may prevent hyperthyroid effects, particularly in large breed dogs. (Ferguson 2002)

■ CATS:

For hypothyroidism:

- a) 0.05–0.1 mg per cat PO once daily. Monitoring and dosage adjustments as above for dogs. (Scott-Moncrieff and Guptill-Yoran 2000)
- b) Initially, 0.05–0.1 mg once daily. Wait a minimum of 4–6 weeks to assess cat's clinical response to treatment. Then obtain a serum T₄ level prior to, and 6–8 hours after, dosing. Increase or decrease dose and/or dosing frequency after reviewing these values and clinical response. If levothyroxine is ineffective, may try liothyronine. (Feldman and Nelson 1987d)

■ HORSES:

For hypothyroidism:

- a) 10 mg in 70 mL of corn syrup once daily. Monitor T₄ levels one week after initiation of therapy. Obtain one blood sample just before administration and on sample 2–3 hours after dosing. (Chen and Li 1987)

For adjunctive treatment of equine metabolic syndrome to lower the risk for laminitis:

- a) 48 mg (total dose) in the feed once daily for 3–6 months. When discontinuing treatment, wean off the drug by reducing dose to 24 mg a day for 2 weeks, then 12 mg a day for 2 weeks. The benefits of longer treatment at lower dosages of levothyroxine have not been evaluated. (Frank 2007)

■ BIRDS:

For hypothyroidism:

- a) One 0.1 mg tablet in 30 mL–120 mL of water daily; stir water and offer for 15 minutes and remove. Use high dose for budgerigars and low dose for water drinkers. Used for respiratory clicking, vomiting in budgerigars and thyroid responsive problems. (Clubb 1986)

■ REPTILES:

For hypothyroidism in tortoises:

- a) 0.02 mg/kg PO every other day (Gauvin 1993)

Monitoring

- Therapeutic efficacy should be judged first via clinical effects, and, if necessary serum T₄
- Serum T₄; after therapy is started wait at a week before measuring T₄. Draw level preferably just prior to the next dose. Dosage should generally be reduced if serum thyroxine levels exceed 100 ng/mL or signs of thyrotoxicosis develop.

Client Information

- Clients should be instructed in the importance of compliance with therapy as prescribed.
- Also, review the signs that can be seen with too much thyroid supplementation (see Overdosage section above).

Chemistry/Synonyms

Prepared synthetically for commercial use, levothyroxine sodium is the levo isomer of thyroxine that is the primary secretion of the thyroid gland. It occurs as an odorless, light yellow to buff-colored, tasteless, hygroscopic powder that is very slightly soluble in water and slightly soluble in alcohol. The commercially available powders for injection also contain mannitol.

100 micrograms of levothyroxine is approximately equivalent to 65 mg (1 grain) of desiccated thyroid.

Levothyroxine sodium may also be known as: T₄, T₄ thyroxine sodium, levothyroxin natrium, levothyroxinum natricum, 3,5,3',5'-tetra-iodo-L-thyronine sodium, thyroxine sodium, L-thyroxine sodium, thyroxinum natricum, tirossina, and tiroxina sodica; many trade names are available.

Storage/Stability/Compatibility

Levothyroxine sodium preparations should be stored at room temperature in tight, light-resistant containers. The injectable product should be reconstituted immediately before use; unused injection should be discarded after reconstituting. Do not mix levothyroxine sodium injection with other drugs or IV fluids.

Levothyroxine sodium is reportedly unstable in aqueous solutions. If using a commercial liquid preparation, it is suggested to obtain validated stability data for the product.

Dosage Forms/Regulatory Status

All levothyroxine products require a prescription, but are not necessarily FDA approved. There have been bioavailability differences between products reported. It is recommended to use a reputable product and not to change brands indiscriminately.

VETERINARY-LABELED PRODUCTS:

Levothyroxine Sodium Tablets: 0.1 mg, 0.2 mg, 0.3 mg, 0.4 mg, 0.5 mg, 0.6 mg, 0.7 mg, 0.8 mg, (1 mg *Soloxine*®); *Amtech*® *Levothyroxine Sodium Tablets* (IVX); *Levosyn*® (V.E.T.); *Soloxine*® (Virbac); *Thyro-Tabs*® (Vet-A-Mix); *Thyrosyn*® (Vedco); *Thyroxine-L Tablets*® (Butler); *Thyrozone*® (Phoenix Pharmaceutical); *Thyrokare*® *Tablets* (Neogen); (Rx). Labeled for use in dogs.

Levothyroxine Sodium Tablets Chewable (Veterinary) 0.1 mg, 0.2 mg, 0.3 mg, 0.4 mg, 0.5 mg, 0.6 mg, 0.7 mg, 0.8 mg; *Canine Thyroid Chewable Tablets*® (Pala-Tech); *Nutrived*® *T-4 Chewable Tablets* (Vedco); *Heska Thyromed*® *Chewable Tablets* (Heska); (Rx). Labeled for use in dogs.

Levothyroxine Oral Solution: 1 mg/mL in 30 mL bottles: *Leventa*® *Oral Solution* (Intervet); (Rx) Labeled for use in dogs.

Levothyroxine Sodium Powder (Veterinary): 0.22% (1 gram of T₄ in 454 grams of powder): One level teaspoonful contains 12 mg of T₄. Available in 1 lb. and 10 lb. containers; *Equine Thyroid Supplement*® (Pala-Tech); *Thyrozone Powder*® (Phoenix Pharmaceutical); *Levoxine*® *Powder* (First Priority); *Thyro-L*® (Vet-A-Mix); *Throxine-L*® *Powder* (Butler); *Equi-Phar Thyrosyn Powder*® (Vedco); *Thyrokare*® *Powder* (Neogen); (Rx). Labeled for use in horses.

HUMAN-LABELED PRODUCTS:

Levothyroxine Sodium Tablets: 0.025 mg, 0.05 mg, 0.075 mg, 0.088 mg, 0.1 mg, 0.112 mg, 0.125 mg, 0.137 mg, 0.15 mg, 0.175 mg, 0.2 mg & 0.3 mg; *Synthroid*® (Abbott); *Levothroid*® (Forest); *Levoxyl*® (Jones Pharma); *Thyro-Tabs*® (Lloyd); *Unithroid*® (Lannett); generic; (Rx)

Levothyroxine Powder for Injection lyophilized: 200 micrograms & 500 micrograms in 10 mL vials; generic; (Rx)

LIDOCAINE HCL (SYSTEMIC)

(līe-doe-kane) Xylocaine®

ANTIARRHYTHMIC/LOCAL ANESTHETIC

Prescriber Highlights

- ▶ Local anesthetic & antiarrhythmic agent; may be useful to prevent post-operative ileus, reperfusion injury in horses
- ▶ Contraindications: Known hypersensitivity to the amide-class local anesthetics, severe degree of SA, AV, or intra-ventricular heart block (if not being artificially paced), or Adams-Stokes syndrome
- ▶ Caution: Liver disease, congestive heart failure, shock, hypovolemia, severe respiratory depression, marked hypoxia, bradycardia, or incomplete heart block having VPC's, unless the heart rate is first accelerated
- ▶ Cats might be more sensitive to the CNS effects of lidocaine; use with caution
- ▶ Patients susceptible to malignant hyperthermia should receive intensified monitoring
- ▶ Adverse Effects: Most common adverse effects reported are dose related (serum level) & mild. CNS signs include drowsiness, depression, ataxia, muscle tremors, etc.; nausea & vomiting (usually transient). Adverse cardiac effects usually only at high plasma concentrations
- ▶ When an IV bolus is given too rapidly, hypotension may occur
- ▶ Do NOT use the product containing epinephrine intravenously
- ▶ Drug interactions

Uses/Indications

Besides its use as a local and topical anesthetic agent, lidocaine is used to treat ventricular arrhythmias, principally ventricular tachycardia and ventricular premature complexes in all species. Cats may be more sensitive to the drug and some clinicians feel that it should not be used in this species as an antiarrhythmic, but this remains controversial. In horses, lidocaine may be useful to prevent post-operative ileus and reperfusion injury.

Pharmacology/Actions

Lidocaine is considered to be a class IB (membrane-stabilizing) antiarrhythmic agent. It is thought that lidocaine acts by combining with fast sodium channels when inactive which inhibits recovery after repolarization. Class IB agents demonstrate rapid rates of attachment and dissociation to sodium channels. At therapeutic levels, lidocaine causes phase 4 diastolic depolarization attenuation, decreased automaticity, and either a decrease or no change in membrane responsiveness and excitability. These effects will occur at serum levels that will not inhibit the automaticity of the SA node, and will have little effect on AV node conduction or His-Purkinje conduction.

Lidocaine apparently has some enhancing effects on intestinal motility in patients with postoperative ileus. The mechanism for this effect is not well understood, but probably involves more than just blocking increased sympathetic tone.

Lidocaine has been shown to be a scavenger of reactive oxygen species (ROS) and lipid peroxidation

Pharmacokinetics

Lidocaine is not effective orally as it has a high first-pass effect. If very high oral doses are given, toxic signs occur (due to active metabolites?) before therapeutic levels can be reached. Following a therapeutic IV bolus dose, the onset of action is generally within 2 minutes and has duration of action of 10–20 minutes. If a constant infusion is begun without an initial IV bolus, it may take up to an hour for therapeutic levels to be reached. IM injections may be given every 1.5 hours in the dog, but because monitoring and adjusting dosages are difficult, it should be reserved for cases where IV infusions are not possible.

After injection, the drug is rapidly redistributed from the plasma into highly perfused organs (kidney, liver, lungs, heart) and distributed widely throughout body tissues. It has a high affinity for fat and adipose tissue and is bound to plasma proteins, primarily α_1 -acid glycoprotein. It has been reported that lidocaine binding to this protein is highly variable and concentration dependent in the dog and may be higher in dogs with inflammatory disease. Lidocaine is distributed into milk. The apparent volume of distribution (V_d) has been reported to be 4.5 L/kg in the dog.

Lidocaine is rapidly metabolized in the liver to active metabolites (MEGX and GX). The terminal half-life of lidocaine in humans is 1.5–2 hours and has been reported to be 0.9 hours in the dog. The half-lives of lidocaine and MEGX may be prolonged in patients with cardiac failure or hepatic disease. Less than 10% of a parenteral dose is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

Cats tend to be more sensitive to the CNS effects of lidocaine; use with caution. Lidocaine is contraindicated in patients with known hypersensitivity to the amide-class local anesthetics, a severe degree of SA, AV or intraventricular heart block (if not being artificially paced), or Adams-Stokes syndrome. The use of lidocaine in patients with Wolff-Parkinson-White (WPW) syndrome is controversial. Some manufacturers state its use is contraindicated, but several physicians have used the drug in people.

Lidocaine should be used with caution in patients with liver disease, congestive heart failure, shock, hypovolemia, severe respiratory depression, or marked hypoxia. It should also be used with caution in patients with bradycardia or incomplete heart block having VPC's, unless the heart rate is first accelerated. Patients susceptible to developing malignant hyperthermia should receive lidocaine with intensified monitoring.

When preparing lidocaine for intravenous injection, be certain of the concentration and do not use products containing epinephrine.

Adverse Effects

At usual doses and if the serum level remains within the proposed therapeutic range (1–5 micrograms/mL), serious adverse reactions are quite rare. The most common adverse effects reported are dose related (serum level) and mild. CNS signs include drowsiness, depression, ataxia, muscle tremors, etc. Nausea and vomiting may occur, but are usually transient. Adverse cardiac effects generally only occur at high plasma concentrations and are usually associated with PR and QRS interval prolongation and QT interval shortening. Lidocaine may increase ventricular rates if used in patients with atrial fibrillation. If an IV bolus is given too rapidly, hypotension may occur.

Be certain not to use the product that contains epinephrine intravenously.

Reproductive/Nursing Safety

In humans, the FDA categorizes systemic lidocaine as category B for use during pregnancy (*Animal studies have not yet demonstrated*

risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), systemic lidocaine is categorized as in class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Lidocaine is excreted in concentrations of approximately 40% of that found in the serum and would unlikely to pose significant risk to nursing offspring.

Overdosage/Acute Toxicity

In dogs, if serum levels of >8 micrograms/mL are attained, toxicity may result. Signs may include ataxia, nystagmus, depression, seizures, bradycardia, hypotension and, at very high levels, circulatory collapse. Because lidocaine is rapidly metabolized, cessation of therapy or reduction in infusion rates with monitoring may be all that is required for minor signs. Seizures or excitement may be treated with diazepam, or a short or ultrashort acting barbiturate. Longer acting barbiturates (e.g., pentobarbital) should be avoided. Should circulatory depression occur, treat with fluids, pressor agents and, if necessary, begin CPR.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lidocaine and may be of significance in veterinary patients:

- **ANTIARRHYTHMICS, OTHER** (e.g., **procainamide, quinidine, propranolol, phenytoin**): When administered with lidocaine may cause additive or antagonistic cardiac effects and toxicity may be enhanced
- **CIMETIDINE**: Lidocaine levels or effects may be increased
- **PHENYTOIN**: May increase lidocaine metabolism; decrease levels
- **PROPRANOLOL**: Lidocaine levels or effects may be increased
- **SUCCINYLCHOLINE**: Large doses of lidocaine may prolong succinylcholine-induced apnea

Laboratory Considerations

- Lidocaine may cause increased **creatinine kinase** levels (CK).

Doses

■ DOGS:

- a) Initial bolus of 2 mg/kg slowly IV, up to 8 mg/kg; or rapid IV infusion of 0.8 mg/kg/minute, if effective, then give constant rate infusion of 25–80 mcg/kg/minute (0.025–0.08 mg/kg/minute) (Ware 2000)
- b) For rapid conversion of life-threatening, incessant, unstable ventricular tachycardia: Initial IV bolus of 1–2 mg/kg preferably over 30 seconds to judge response, higher doses may be required but rarely need to give 4 mg/kg. Once effectiveness determined, begin constant rate infusion at 25–80 mcg/kg/minute. Adjust dose to attain efficacy but without side effects. To prevent adverse effects total dose should not exceed 8 mg/kg over approximately one hour. Alternatively may give lidocaine at 4 mg/kg IM, but not if shock is present. Effects generally are seen in 10–15 minutes, and persist for about 90 minutes. (Moise 2000)
- c) For ventricular arrhythmias: Initial dosage of 2–8 mg/kg IV slowly is given to effect while monitoring ECG; then following by a CRI of 25–75 mcg/kg/minute starting at a high dose and tapering down when possible. (Macintire 2006a)

■ **CATS:**

CAUTION: Cats are reportedly very sensitive to the CNS effects of lidocaine, monitor carefully and treat seizures with diazepam.

- Initially, IV bolus of 0.25–0.5 mg/kg given slowly; can repeat at 0.15–0.25 mg/kg in 5–20 minutes; if effective, 10–20 mcg/kg/minute (0.01–0.02 mg/kg/min) as a constant rate IV infusion (Ware 2000)
- 0.25–0.5 mg/kg slow IV, with the possibility of repeating up to twice more if needed. If diluting for accurate dosing, use an insulin/tuberculin syringe. May be used as first-line therapy, or after propranolol, if it was ineffective. (Cote 2004)

■ **HORSES: (Note: ARCI UCGFS Class 2 Drug)**

For ventricular tachyarrhythmias:

- Initially IV bolus of 1–1.5 mg/kg. Will generally distinguish between ventricular tachyarrhythmias (effective) and supraventricular tachyarrhythmias (no effect). To maintain effect, a constant IV infusion will be required. (Hilwig 1987)
- 0.25–0.5 mg/kg IV (slowly) every 5–10 minutes up to a total dose of 1.5 mg/kg (Mogg 1999)

For postoperative ileus:

- Initially, IV bolus of 1.3 mg/kg followed by a IV infusion of 0.05 mg/kg/minute for 24 hours (Malone, Turner et al. 1999)

Monitoring

- ECG
- Signs of toxicity (see Adverse Effects and Overdosage)
- If available and indicated, serum levels may be monitored. Therapeutic levels are considered to range from 1–6 micrograms/mL.

Client Information

- This drug should only be used systemically by professionals familiar with its use and in a setting where adequate patient monitoring can be performed.

Chemistry/Synonyms

A potent local anesthetic and antiarrhythmic agent, lidocaine HCl occurs as a white, odorless, slightly bitter tasting, crystalline powder with a melting point between 74°–79°C and a pK_a of 7.86. It is very soluble in water and alcohol. The pH of the commercial injection is adjusted to 5–7, and the pH of the commercially available infusion in dextrose 5% is adjusted to 3.5–6.

Lidocaine may also be known as: lidocaini hydrochloridum, and lignocaine hydrochloride; many trade names are available; a common trade name is *Xylocaine*® (Astra).

Storage/Stability/Compatibility/Preparation

Lidocaine for injection should be stored at temperatures less than 40°C and preferably between 15–30°C; avoid freezing.

Lidocaine is physically **compatible** with most commonly used IV infusion solutions, including D5W, lactated Ringer's, saline, and combinations of these. It is also reportedly physically **compatible** with: aminophylline, bretylium tosylate, calcium chloride/gluceptate/gluconate, carbenicillin disodium, chloramphenicol sodium succinate, chlorothiazide sodium, cimetidine HCl, dexamethasone sodium phosphate, digoxin, diphenhydramine HCl, dobutamine HCl, ephedrine sulfate, erythromycin lactobionate, glycopyrrolate, heparin sodium, hydrocortisone sodium succinate, hydroxyzine HCl, insulin (regular), mephentermine sulfate, metaraminol bitartrate, methicillin sodium, metoclopramide HCl, nitrofurantoin sodium, oxytetracycline HCl, penicillin G potassium, pentobarbital sodium, phenylephrine HCl, potassium chloride, procainamide HCl, prochlorperazine edisylate, promazine HCl, sodium bicarbon-

ate, sodium lactate, tetracycline HCl, verapamil HCl, and Vitamin B-Complex with C.

Lidocaine **may not be compatible** with dopamine, epinephrine, isoproterenol, or norepinephrine as these require low pH's for stability. Lidocaine is reportedly physically **incompatible** when mixed with: ampicillin sodium, cefazolin sodium, methohexital sodium, or phenytoin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

To prepare IV infusion solution using the veterinary 2% solution add 1 gram (50 mL of 2% solution to 1 liter of D5W or other compatible solution, this will give an approximate concentration of 1 mg/mL (1000 micrograms/mL). When using a mini-drip (60 drops/mL) IV set, each drop will contain approximately 17 micrograms. In small dogs and cats, a less concentrated solution may be used for greater dosage accuracy. When preparing solution be certain that you are not using the lidocaine product that contains epinephrine.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

There are injectable lidocaine products labeled for use in veterinary medicine (dogs, cats, horses, and cattle) as an injectable anesthetic, but it is not approved for use as an antiarrhythmic agent. Information regarding its use in food-producing species is conflicting; when using a food animal it is suggested to contact FARAD (see appendix).

Lidocaine HCl for Injection: 2% (20 mg/mL) in 100 mL & 250 mL multi-use vials; (contains preservatives). Manufacturers include: Vedco, Phoenix Pharmaceutical, Aspen, AgriLabs, IVX, Butler, & RXV; (Rx)

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Lidocaine Hydrochloride Injection: 0.5%, 1%, 1.5%, 2% & 4% in 5 mL, 10 mL, 20 mL, 30 mL & 50 mL single- & multi-dose vials, 2 mL & 5 mL amps, 5 mL syringe with laryngotracheal cannula & 1.8 mL cartridges; *Xylocaine*® & *Xylocaine MPF*® (AstraZeneca); generic; (Rx)

Premixed with D5W for IV infusion in concentrations of 2 mg/mL, 4 mg/mL, and 5 mg/mL, injections with epinephrine, topical liquids, patches, ointment, cream, lotion, gel, spray, & jelly available.

LINCOMYCIN HCL

(lin-koe-mye-sin) Lincocin®, Lincomix®

LINCOSAMIDE ANTIBIOTIC

Prescriber Highlights

- ▶ Lincosamide antibiotic similar to clindamycin; broad spectrum against many anaerobes, gram-positive aerobic cocci, *Toxoplasma*, etc.
- ▶ Contraindications: Horses, Rodents, Ruminants, Lagomorphs; Hypersensitivity to lincosamides
- ▶ Caution: Liver or renal dysfunction; consider reducing dosage if severe
- ▶ Adverse Effects: Gastroenteritis, pain at injection site if given IM; rapid IV administration can cause hypotension & cardiopulmonary arrest
- ▶ Distributed into milk; may cause diarrhea in nursing animals
- ▶ Drug interactions

Uses/Indications

Lincomycin has dosage forms approved for use in dogs, cats, swine, and in combination with other agents for chickens. Because clindamycin is generally better absorbed, more active, and probably less toxic, it has largely supplanted the use of lincomycin for oral and injectable therapy in small animals, but some clinicians believe that clindamycin does not offer enough clinically significant improvements over lincomycin to justify its higher cost. For further information, refer to the Pharmacology or Doses sections.

Pharmacology/Actions

The lincosamide antibiotics lincomycin and clindamycin, share mechanisms of action and have similar spectrums of activity although lincomycin is usually less active against susceptible organisms. Complete cross-resistance occurs between the two drugs; at least partial cross-resistance occurs between the lincosamides and erythromycin. They may act as bacteriostatic or bactericidal agents, depending on the concentration of the drug at the infection site and the susceptibility of the organism. The lincosamides are believed to act by binding to the 50S ribosomal subunit of susceptible bacteria, thereby inhibiting peptide bond formation.

Most aerobic gram-positive cocci are susceptible to the lincosamides (*Strep. faecalis* is not), including staphylococcus and streptococci. Other organisms that are generally susceptible include: *Corynebacterium diphtheriae*, *Nocardia asteroides*, *Erysipelothrix*, and *Mycoplasma* spp. Anaerobic bacteria that may be susceptible to the lincomycin include: *Clostridium perfringens*, *C. tetani* (not *C. difficile*), *Bacteroides* (including many strains of *B. fragilis*), *Fusobacterium*, *Peptostreptococcus*, *Actinomyces*, and *Peptococcus*.

Pharmacokinetics

The pharmacokinetics of lincomycin have not apparently been extensively studied in veterinary species. Unless otherwise noted, the following information applies to humans. The drug is rapidly absorbed from the gut, but only about 30–40% of the total dose is absorbed. Food both decreases the extent and the rate of absorption. Peak serum levels are attained about 2–4 hour after oral dosing. IM administration gives peak levels about double those reached after oral dosing, and peak at about 30 minutes post injection.

Lincomycin is distributed into most tissues. Therapeutic levels are achieved in bone, synovial fluid, bile, pleural fluid, peritoneal fluid, skin, and heart muscle. CNS levels may reach 40% of those in the serum if meninges are inflamed. Lincomycin is bound from 57–72% to plasma proteins, depending on the drug's concentration. The drug crosses the placenta and can be distributed into milk at concentrations equal to those found in plasma.

Lincomycin is partially metabolized in the liver. Unchanged drug and metabolites are excreted in the urine, feces and bile. Half-lives can be prolonged in patients with renal or hepatic dysfunction. The elimination half-life of lincomycin is reportedly 3–4 hours in small animals.

Contraindications/Precautions/Warnings

Although there have been case reports of parenteral administration of lincosamides to horses, cattle and sheep, the lincosamides are considered *contraindicated* for use in **rabbits, hamsters, guinea pigs, horses, and ruminants** because of serious gastrointestinal effects that may occur, including death.

Lincomycin is contraindicated in patients with known hypersensitivity to it or having a preexisting monilial infection.

Adverse Effects

Adverse effects reported in dogs and cats include gastroenteritis (emesis, loose stools, and infrequently bloody diarrhea in dogs). IM injections reportedly cause pain at the injection site. Rapid intravenous administration can cause hypotension and cardiopulmonary arrest.

Swine may develop gastrointestinal disturbances while receiving the medication.

Reproductive/Nursing Safety

Lincomycin crosses the placenta and cord blood concentrations are approximately 25% of those found in maternal serum. Safe use during pregnancy has not been established, but neither has the drug been implicated in causing teratogenic effects.

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as in class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Because lincomycin is distributed into milk, nursing animals of mothers given lincomycin may develop diarrhea.

Overdosage/Acute Toxicity

There is little information available regarding overdoses of this drug. In dogs, oral doses of up to 300 mg/kg/day for up to one year or parenterally at 60 mg/kg/day apparently did not result in toxicity.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lincomycin and may be of significance in veterinary patients:

- **CYCLOSPORINE:** Lincomycin may reduce levels
- **ERYTHROMYCIN:** *In vitro* antagonism when used with lincomycin; concomitant use should probably be avoided
- **KAOLIN:** Kaolin (found in several over-the-counter antidiarrheal preparations) has been shown to reduce the absorption of linco-

mycin by up to 90% if both are given concurrently; if both drugs are necessary, separate doses by at least 2 hours

- **NEUROMUSCULAR BLOCKING AGENTS** (e.g., **pancuronium**): Lincomycin possesses intrinsic neuromuscular blocking activity and should be used cautiously with other neuromuscular blocking agents

Laboratory Considerations

- Slight increases in **liver function tests** (AST, ALT, Alk. Phosph.) may occur. There is apparently not any clinical significance associated with these increases.

Doses

■ DOGS:

For susceptible infections:

- a) For skin and soft tissue infections: 15.4 mg/kg PO q8h or 22 mg/kg PO q12h. Treatment for superficial pyoderma 21–42 days; for deep, resistant pyoderma 56 days;

For systemic infections: 22 mg/kg IM, SC, or IV (must be diluted and given as a slow drip infusion) q24h or 11 mg/kg IM or SC q12h for 12 days or less.

For bacteremia, sepsis: 11–22 mg/kg IV q8h for 12 days or less. (Greene, Hartmann et al. 2006)

- b) For pyoderma: 20 mg/kg twice daily (Halliwell 2002)
- c) For superficial pyodermas: 20 mg/kg PO q12h (White 2007)
- d) For pyoderma: 22 mg/kg PO twice daily; good for first time pyodermas. (Logas 2005b)

■ CATS:

For susceptible infections:

- a) For skin and soft tissue infections: 11 mg/kg IM q12h or 22 mg/kg IM q24h. Treatment for 12 days or less;
- For systemic infections: 15 mg/kg PO q8h or 22 mg/kg PO q12h. Treatment for 12 days or less. (Greene, Hartmann et al. 2006)

■ FERRETS:

For susceptible infections:

- a) 10–15 mg/kg PO three times daily; 10 mg/kg IM twice daily (Williams 2000)

■ SWINE:

For susceptible infections:

- a) For mycoplasmal (*M. hyopneumoniae*) pneumonia: Fed at 200 grams per ton of feed for 21 days or 11 mg/kg IM once daily (Amass 1999)
- b) 11 mg/kg IM once daily for 3–7 days; or added to drinking water at a rate of 250 mg/gallon (average of 8.36 mg/kg/day) (Label directions; *Lincocin*®—Upjohn)

Monitoring

- Clinical efficacy
- Adverse effects; particularly severe diarrheas

Client Information

- Clients should be instructed to report the incidence of severe, protracted, or bloody diarrhea to the veterinarian.

Chemistry/Synonyms

An antibiotic obtained from cultures of *Streptomyces lincolnensis*, lincomycin is available commercially as the monohydrate hydrochloride. It occurs as a white to off-white, crystalline powder that is freely soluble in water. The powder may have a faint odor and has a pK_a of 7.6. The commercially available injection has a pH of 3–5.5 and occurs as a clear to slightly yellow solution.

Lincomycin may also be as: U-10149, NSC-70731, *Anbycin*®, *Frademicina*®, *Fredcina*®, *Linco*®, *Lincocin*®, *LincoMed*®, *Lincomix*®, *Linco-Ped*®, *Lincono*®, and *Macrolin*®.

Storage/Stability/Compatibility

Lincomycin capsules, tablets and soluble powder should be stored at room temperature (15–30°C) in tight containers. Lincomycin injectable products should be stored at room temperature; avoid freezing.

Lincomycin HCl for injection is reportedly physically **compatible** for at least 24 hours in the following IV infusion solutions and drugs: D5W, D5W in sodium chloride 0.9%, D10W, sodium chloride 0.9%, Ringer's injection, amikacin sulfate, cephalothin sodium, chloramphenicol sodium succinate, cimetidine HCl, cytarabine, heparin sodium, penicillin G potassium/sodium (4 hours only), polymyxin B sulfate, tetracycline HCl, and vitamin B-complex with C.

Drugs that are reportedly physically **incompatible** when mixed with lincomycin, data conflicts, or compatibility is concentration and/or time dependent include: ampicillin sodium, carbenicillin disodium, methicillin sodium, and phenytoin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Lincomycin Oral Tablets: 100 mg, 200 mg, 500 mg; *Lincocin*® (Pharmacia); (Rx). Approved for use in dogs and cats.

Lincomycin Oral Solution: 50 mg/mL in 20 mL dropper bottles; *Lincocin*® *Aquadrops* (Pharmacia); (Rx). Approved for use in dogs and cats.

Lincomycin Sterile Injection: 100 mg/mL in 20 mL vials; *Lincocin*® (Pharmacia); (Rx). Approved for use in dogs and cats.

Lincomycin Sterile Injection: 25 mg/mL, 100 mg/mL & 300 mg/mL in 100 mL vials; approved for use in swine. Slaughter withdrawal (when used as labeled) = 48 hours. *Lincocin*® *Sterile Solution* (Pharmacia and Upjohn); *Lincomix*® *Injectable* (Pharmacia); *LincoMed*® (Bimeda); generic; (OTC)

There are also several lincomycin combination feed/water additive products for use in swine and/or poultry.

HUMAN-LABELED PRODUCTS:

Lincomycin Capsules: 500 mg (as hydrochloride); *Lincocin*® (Upjohn); (Rx)

Lincomycin Injection: 300 mg (as hydrochloride)/mL in 2 mL and 10 mL vials; *Lincocin*® (Upjohn), (Rx)

LIOTHYRONINE SODIUM

(lye-oh-thye-roe-neen) Cytomel®, Triostat®

THYROID HORMONE

Prescriber Highlights

- ▶ **Form of T3 (active thyroid hormone) used for hypothyroidism particularly in animals unresponsive to T4**
- ▶ **Shorter duration of effect than levothyroxine**
- ▶ **Contraindications: Acute myocardial infarction, thyrotoxicosis, or untreated adrenal insufficiency**
- ▶ **Caution: Concurrent hypoadrenocorticism (treated), cardiac disease, diabetes, or elderly**
- ▶ **Adverse Effects: Only associated with OD's (tachycardia, polyphagia, PU/PD, excitability, nervousness, & excessive panting); some cats may appear apathetic**
- ▶ **Drug-drug; drug-lab interactions**

Uses/Indications

Because of its shorter duration of action, liothyronine is generally not considered the drug of first choice in treating hypothyroidism. Infrequently, animals not responding to levothyroxine may respond to liothyronine.

Pharmacology/Actions

Thyroid hormones affect the rate of many physiologic processes including: fat, protein, and carbohydrate metabolism, increasing protein synthesis, increasing gluconeogenesis, and promoting mobilization and utilization of glycogen stores. Thyroid hormones also increase oxygen consumption, body temperature, heart rate and cardiac output, blood volume, enzyme system activity, and growth and maturity. Thyroid hormone is particularly important for adequate development of the central nervous system. While the exact mechanisms how thyroid hormones exert their effects are not well understood, it is known that thyroid hormones (primarily triiodothyronine) act at the cellular level.

In humans, triiodothyronine (T₃) is the primary hormone responsible for activity. Approximately 80% of T₃ found in the peripheral tissues is derived from thyroxine (T₄) which is the principle hormone released by the thyroid.

Pharmacokinetics

In dogs, peak plasma levels of liothyronine occur 2–5 hours after oral dosing. The plasma half-life is approximately 5–6 hours. In contrast to levothyroxine, it is believed that liothyronine is nearly completely absorbed by dogs and absorption is not as affected by stomach contents, intestinal flora changes, etc.

Contraindications/Precautions/Warnings

Liothyronine (and other replacement thyroid hormones) are contraindicated in patients with acute myocardial infarction, thyrotoxicosis, or untreated adrenal insufficiency. It should be used with caution, and at a lower initial dosage, in patients with concurrent hypoadrenocorticism (treated), cardiac disease, diabetes, or in elderly patients.

Adverse Effects

When administered at an appropriate dose to patients requiring thyroid hormone replacement, there should not be any adverse effects associated with therapy. For adverse effects associated with overdosage, see below.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category A for use during pregnancy (*Adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Minimal amounts of thyroid hormones are excreted in milk and should not adversely affect nursing offspring.

Overdosage/Acute Toxicity

Chronic overdosage will produce signs of hyperthyroidism, including tachycardia, polyphagia, PU/PD, excitability, nervousness, and excessive panting. Dosage should be reduced and/or temporarily withheld until signs subside. Some (10%?) cats may exhibit signs of “apathetic” (listlessness, anorexia, etc.) hyperthyroidism.

Acute massive overdosage can produce signs resembling thyroid storm. After oral ingestion, treatment to reduce absorption of drug should be accomplished using standard protocols (emetics or gastric lavage, cathartics, charcoal) unless contraindicated by the patient's condition. Treatment is supportive and symptomatic. Oxygen, artificial ventilation, cardiac glycosides, beta-blockers (e.g., propranolol), fluids, dextrose, and antipyretic agents have all been suggested for use if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving liothyronine and may be of significance in veterinary patients:

- **ANTIDEPRESSANTS, TRICYCLIC/TETRACYCLIC:** Increased risk for CNS stimulation and cardiac arrhythmias
- **ANTIDIABETIC AGENTS (insulin, oral agents):** Levothyroxine may increase requirements for insulin or oral agents
- **CHOLESTYRAMINE:** May reduce liothyronine absorption; separate doses by 4 hours
- **DIGOXIN:** Potential for reduced digoxin levels
- **KETAMINE:** May cause tachycardia and hypertension
- **SYMPATHOMIMETIC AGENTS (epinephrine, norepinephrine, etc.):** Levothyroxine can potentiate effects
- **WARFARIN:** Thyroid hormones increase the catabolism of vitamin K-dependent clotting factors that may increase the anticoagulation effects in patients on warfarin

Laboratory Considerations

The following drugs may have effects on thyroid function tests; evaluate results accordingly:

- **EFFECTS ON SERUM T₄:** aminoglutethimide↓, anabolic steroids/androgens↓, antithyroid drugs (PTU, methimazole)↓, asparaginase↓, barbiturates↓, corticosteroids↓, danazol↓, diazepam↓, estrogens↑ (**Note:** estrogens may have no effect on canine T₃ or T₄ concentrations), fluorouracil↑, heparin↓, insulin↑, lithium carbonate↓, mitotane (o,p-DDD)↓, nitroprusside↓, phenylbutazone↓, phenytoin↓, propranolol↑, salicylates (large doses)↓, and sulfonyleureas↓.
- **EFFECTS ON SERUM T₃:** antithyroid drugs (PTU, methimazole)↓, barbiturates↓, corticosteroids↓, estrogens↑, fluorouracil↑, heparin↓, lithium carbonate↓, phenytoin↓, propranolol↓, salicylates (large doses)↓, and thiazides↑.
- **EFFECTS ON T₃ UPTAKE RESIN:** anabolic steroids/androgens↑, antithyroid drugs (PTU, methimazole)↓, asparaginase↑, corticosteroids↑, danazol↑, estrogens↓, fluorouracil↓, heparin↑, lithium carbonate↓, phenylbutazone↑, and salicylates (large doses)↑.
- **EFFECTS ON SERUM TSH:** aminoglutethimide↑, antithyroid drugs (PTU, methimazole)↑, corticosteroids↓, danazol↓, and lithium carbonate↑.

■ **EFFECTS ON FREE THYROXINE INDEX (FTI):** antithyroid drugs (PTU, methimazole)↓, barbiturates↓, corticosteroids↓, heparin↑, lithium carbonate↓, and phenylbutazone↓.

Doses

■ DOGS:

For hypothyroidism:

- Initially, 4–6 micrograms/kg PO q8h. Some dogs may require less frequent dosing (Nelson 1989b)
- If poor absorption of levothyroxine is suspected: 4–6 mcg/kg q8h (Scott-Moncrieff and Gupitill-Yoran 2000)

■ CATS:

For hypothyroidism:

- Initially, 4.4 micrograms/kg PO 2–3 times a day (Feldman and Nelson 1987d)

Monitoring

- Similar to levothyroxine, but T₄ levels will remain low. When monitoring T₃ levels, draw serum just prior to dosing and again 2–4 hours after administering the drug.

Client Information

- Clients should be instructed in the importance of compliance with therapy as prescribed
- Also, review the signs that can be seen with too much thyroid supplementation

Chemistry/Synonyms

A synthetically prepared sodium salt of the naturally occurring hormone T₃, liothyronine sodium occurs as an odorless, light tan crystalline powder. It is very slightly soluble in water and slightly soluble in alcohol. Each 25 micrograms of liothyronine is approximately equivalent to 60–65 mg (1 grain) of thyroglobulin or desiccated thyroid and 100 micrograms or less of levothyroxine.

Liothyronine sodium may also be known as: T₃, T₃ thyronine sodium, L-triiodothyronine, sodium L-triiodothyronine, liothyroninum natricum, sodium liothyronine, l-tri-iodothyronine sodium, 3,5,3'-Tri-iodo-L-thyronine sodium, *Cynomel*®, *Cytomel*®, *Dispon*®, *Neo-Tiroimade*®, *T3*®, *Tertroxin*®, *Thybon*®, *Thyrotardin N*®, *Ti-Tre*®, *Triiodothyronine Injection*®, *Triostat*®, *Triyodisan*®, and *Triyotex*®.

Storage/Stability/Compatibility

Liothyronine tablets should be stored at room temperature (15–30°C) in tight containers.

The injection should be stored refrigerated (2–8°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Liothyronine Sodium Tablets: 5 mcg, 25 mcg & 50 mcg; *Cytomel*® (Monarch); (Rx)

Liothyronine Sodium Injection: 10 mcg/mL in 1 mL vials; *Triostat*® (Monarch); Liothyronine Sodium (X-Gen); (Rx)

LISINOPRIL

(Iye-*sin*-oh-pril) Prinivil®, Zestril®

ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITOR

Prescriber Highlights

- ACE inhibitor used primarily as a vasodilator in the treatment of heart failure or hypertension; may also be of benefit in the treatment of chronic renal failure or protein losing nephropathies
- May be less expensive than other ACE inhibitors & probably can be dosed once daily
- Not as much information available or experience as enalapril in dogs or cats
- Contraindications: Hypersensitivity to ACE inhibitors
- Caution: Renal insufficiency (doses may need to be reduced), patients with hyponatremia, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities, or a collagen vascular disease (e.g., SLE)
- Adverse Effects: GI distress (anorexia, vomiting, diarrhea); Potentially: weakness, hypotension, renal dysfunction, & hyperkalemia

Uses/Indications

The principle uses of lisinopril in veterinary medicine at present are as a vasodilator in the treatment of heart failure or hypertension. Recent studies have demonstrated that ACE inhibitors, particularly when used in conjunction with furosemide, do improve the quality of life in dogs with heart failure. It is not clear, however, whether it has any significant effect on survival times. Lisinopril may also be of benefit in treating the effects associated with valvular heart disease (mitral regurgitation) and left to right shunts. It is being explored as adjunctive treatment in chronic renal failure and in protein losing nephropathies.

Lisinopril may have advantages over other ACE inhibitors in that it may be dosed once daily and less expensive. Disadvantages are that it is only available in human labeled dosage forms and there is much less published information on its use (efficacy, safety, dosing) in veterinary species.

Pharmacology/Actions

Unlike enalapril, lisinopril does not need to be converted in the liver to an active metabolite. Lisinopril prevents the formation of angiotensin-II (a potent vasoconstrictor) by competing with angiotensin-I for the enzyme angiotensin-converting enzyme (ACE). ACE has a much higher affinity for lisinopril than for angiotensin-I. Because angiotensin-II concentrations are decreased, aldosterone secretion is reduced and plasma renin activity is increased. Lisinopril has a higher affinity for ACE than either enalaprilat or captopril.

The cardiovascular effects of lisinopril in patients with CHF include decreased total peripheral resistance, pulmonary vascular resistance, mean arterial and right atrial pressures, and pulmonary capillary wedge pressure, no change or decrease in heart rate, and increased cardiac index and output, stroke volume, and exercise tolerance. Renal blood flow can be increased with little change in hepatic blood flow. In animals with glomerular disease, ACE inhibitors probably decrease proteinuria and help to preserve renal function.

Pharmacokinetics

In dogs, lisinopril's bioavailability ranges from 25–50% with peak levels occurring about 4 hours after dosing. Lisinopril is distributed poorly into the CNS. It is unknown if it is distributed into maternal milk, but it does cross the placenta. Half-lives are increased in patients with renal failure or severe CHF. Duration of action in dogs has been described as being 24 hours, but effects tend to drop off with time.

Contraindications/Precautions/Warnings

Lisinopril is contraindicated in patients who have demonstrated hypersensitivity to the ACE inhibitors. It should be used with caution and close supervision in patients with renal insufficiency and doses may need to be reduced.

Lisinopril should be used with caution in patients with hyponatremia or sodium depletion, coronary or cerebrovascular insufficiency, preexisting hematologic abnormalities, or a collagen vascular disease (e.g., SLE). Patients with severe CHF should be monitored very closely upon initiation of therapy.

Adverse Effects

Lisinopril's adverse effect profile in dogs is reportedly similar to other ACE inhibitors, principally GI distress (anorexia, vomiting, diarrhea). Potentially, cough, weakness, hypotension, renal dysfunction, and hyperkalemia could occur. Because it lacks a sulfhydryl group (unlike captopril), there is less likelihood that immune-mediated reactions will occur, but rashes, neutropenia, and agranulocytosis have been reported in humans.

Reproductive/Nursing Safety

Lisinopril crosses the placenta. High doses in rodents have caused decreased fetal weights and increases in fetal and maternal death rates; teratogenic effects have not been reported.

Current recommendations for humans are to discontinue ACE inhibitors as soon as pregnancy is detected. In humans, the FDA categorizes this drug as category **C** for use during the first trimester of pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In humans, the FDA categorizes this drug as category **D** for use during the second and third trimesters of pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is not known whether lisinopril is excreted in milk; use with caution.

Overdosage/Acute Toxicity

There were 598 exposures to lisinopril reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 555 were dogs with 22 showing clinical signs and the remaining cases were 41 cats and 2 birds with no clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy, tachycardia, vomiting, hypersalivation and hypotension.

In overdose situations, the primary concern is hypotension; supportive treatment with volume expansion with normal saline is recommended to correct blood pressure. Because of the drug's long duration of action, prolonged monitoring and treatment may be required. Recent overdoses should be managed using gut-emptying protocols when warranted.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lisinopril and may be of significance in veterinary patients:

- **ANTIDIABETIC AGENTS (insulin, oral agents):** Possible increased risk for hypoglycemia; enhanced monitoring recommended
- **DIURETICS (e.g., furosemide, hydrochlorothiazide):** Potential for increased hypotensive effects; some veterinary clinicians recommend reducing furosemide doses (by 25–50%) when adding ACE-inhibitors to therapy in CHF
- **DIURETICS, POTASSIUM-SPARING (e.g., spironolactone, triamterene):** Increased hyperkalemic effects, enhanced monitoring of serum potassium recommended
- **HYPOTENSIVE AGENTS, OTHER:** Potential for increased hypotensive effect
- **LITHIUM:** Increased serum lithium levels possible; increased monitoring required
- **NSAIDS:** May reduce the anti-hypertensive or positive hemodynamic effects of enalapril; may increase risk for reduced renal function
- **POTASSIUM SUPPLEMENTS:** Increased risk for hyperkalemia

Laboratory Considerations

- ACE inhibitors may cause a reversible decrease in localization and excretion of **iodohippurate sodium** I^{123}/I^{134} , or **Technetium** Tc^{99} pententate renal imaging in the affected kidney in patients with renal artery stenosis, which may lead to confusion in test interpretation.

Doses

■ DOGS:

For adjunctive treatment of heart failure:

- a) 0.5 mg/kg PO q12–24 hours (Ware and Keene 2000)
- b) Usually: 0.5 mg/kg PO once daily (q24h); a dose of 0.25–0.5 mg/kg PO q12h or 1 mg/kg PO once daily may be more effective, but further studies needed to determine clinically effective doses (Kittleson 2000)
- c) 0.5 mg/kg PO q24h (Fuentes 2003)

■ CATS:

For adjunctive treatment of heart failure:

- a) 0.25–0.5 mg/kg PO once daily (Fox 2000)

Monitoring

- Clinical signs of CHF
- Serum electrolytes, creatinine, BUN, urine protein
- CBC with differential, periodic
- Blood pressure (if treating hypertension or signs associated with hypotension arise)

Client Information

- Do not abruptly stop or reduce therapy without veterinarian's guidance
- Contact veterinarian if vomiting or diarrhea persist or are severe or if animal's condition deteriorates.

Chemistry/Synonyms

An oral angiotensin-converting enzyme inhibitor (ACE inhibitor) lisinopril is directly active and not a prodrug like enalapril. It occurs as a white crystalline powder. One mg is soluble in 10 mL of water; 70 mL of methanol. It is practically insoluble in alcohol, chloroform, or ether.

Lisinopril may also be known as: L-154826, lisinoprilum, and MK-521; many trade names are available.

Storage/Stability

Store lisinopril tablets at room temperature in tight containers, unless otherwise directed by manufacturer.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Lisinopril Tablets: 2.5 mg, 5 mg, 10 mg, 20 mg, 30 mg and 40 mg; *Prinivil*® (Merck); *Zestril*® (AstraZeneca); generic; (Rx)

Also available are fixed dose combinations of lisinopril with hydrochlorothiazide.

LOMUSTINE (CCNU)

(loe-mus-teen) CeeNu®

Prescriber Highlights

- ▶ Antineoplastic usually used for CNS neoplasms, mast cell tumors, or as a rescue agent for lymphosarcoma
- ▶ Cautions (risk vs. benefit): Anemia, bone marrow depression, pulmonary function impairment, current infection, impaired renal function, sensitivity to lomustine, or patients that have received previous chemotherapy or radiotherapy
- ▶ Adverse Effects: GI effects (anorexia, vomiting, diarrhea), stomatitis, alopecia, corneal de-epithelization, &, rarely, renal toxicity, hepatotoxicity, & pulmonary infiltrates or fibrosis. Most serious: bone marrow depression (anemia, thrombocytopenia, leukopenia); nadirs in dogs generally occur about 1–3 weeks after treatment
- ▶ Teratogenic

Uses/Indications

Lomustine may be useful in the adjunctive treatment of CNS neoplasms, lymphomas, and mast cell tumors in dogs and cats.

Pharmacology/Actions

While lomustine's mechanism of action is not totally understood, it is believed it acts as an alkylating agent; however, other mechanisms such as carbamoylation and cellular protein modification may be involved; net effects are DNA and RNA synthesis inhibition. Lomustine is cell cycle-phase nonspecific.

Pharmacokinetics

Lomustine is absorbed rapidly and extensively from the GI tract and some absorption occurs after topical administration. Lomustine or its active metabolites are widely distributed in the body. While lomustine is not detected in the CSF, its active metabolites are detected in substantial concentrations. Lomustine is metabolized extensively in the liver to both active and inactive metabolites that are then eliminated primarily in the urine. Lomustine half-life in humans is very short (about 15 minutes), but its biologic activity is significantly longer due to the longer elimination times of active metabolites.

Contraindications/Precautions/Warnings

Lomustine should be used only when its potential benefits outweigh its risks with the following conditions: anemia, bone marrow depression, pulmonary function impairment, current infection, impaired renal function, sensitivity to lomustine, or patients who have received previous chemotherapy or radiotherapy.

Adverse Effects

The most serious adverse effects are bone marrow depression (anemia, thrombocytopenia, leukopenia) and hepatotoxicity. CBC nadirs in dogs generally occur about 1–6 weeks after treatment has begun. In dogs, lomustine may cause delayed, cumulative dose-related, chronic, irreversible hepatotoxicity (Kristal, Rassnick et al. 2004). There are some anecdotal reports of SAME being successfully used to treat lomustine hepatotoxicity. Other potential adverse effects include GI effects (anorexia, vomiting, diarrhea), stomatitis, alopecia, corneal de-epithelization and rarely, renal toxicity, and pulmonary infiltrates or fibrosis.

Cross-resistance may occur between lomustine and carmustine.

Reproductive/Nursing Safety

Lomustine is a teratogen in lab animals. Use only during pregnancy when the benefits to the mother outweigh the risks to the offspring. Lomustine can suppress gonadal function. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Lomustine and its metabolites have been detected in maternal milk. Nursing puppies should receive milk replacer when the bitch is receiving lomustine.

Overdosage/Acute Toxicity

No specific information was located. Because of the potential toxicity of the drug, overdoses should be treated aggressively with gut emptying protocols employed when possible. For further information, refer to an animal poison control center.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lomustine and may be of significance in veterinary patients:

- **IMMUNOSUPPRESSIVE DRUGS, OTHER** (e.g., **azathioprine, cyclophosphamide, corticosteroids**): Use with other immunosuppressant drugs may increase the risk of infection.
- **MYELOSUPPRESSIVE DRUGS, OTHER** (e.g., **chloramphenicol, flucytosine, amphotericin B, or colchicine**): The principal concern with lomustine is with its concurrent use with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs. Bone marrow depression may be additive.
- **VACCINES, LIVE VIRUS**: Live virus vaccines should be used with caution, if at all, during lomustine therapy.

Doses

For more information on using lomustine as part of chemotherapy protocols, refer to the protocols found in the appendix or other dosages/protocols found in numerous references, including: *Withrow and MacEwen's Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

■ DOGS:

For the treatment of neoplasms:

- a) As a rescue agent as part of a protocol for relapsed (after CHOP) canine lymphomas: Lomustine at 70 mg/m² (for dogs 15 kg or more) or 60 mg/m² (for dogs <15 kg) PO every 3 weeks for a total of 5 doses or until disease progression;

Asparaginase at 400 U/kg SC with the first two lomustine doses and then discontinued; Prednisone started at 2 mg/kg PO once daily and tapered to 1 mg/kg PO every other day. If neutrophil count <500 cells/mcL at one week after lomustine, then doses were decreased by 10 mg/m² for subsequent doses. All doses were rounded down to the nearest 10 mg dose. (Saba, Thamm et al. 2007)

- b) As a rescue agent for relapsed canine lymphomas: 90 mg/m² PO every 21 days for 3 cycles, then every 4–6 weeks thereafter (Moore, London et al. 1999)
- c) As a rescue agent for mast cell tumors when other treatment options have failed: 70–90 mg/m² PO every 21 days (Chun 2007b)
- d) 60–80 mg/m² PO q4–6 weeks (Brewer 2003)
- e) 80 mg/m² PO every 3 weeks (Lana 2002)
- f) For cutaneous lymphosarcoma: Isotretinoin at 3–4 mg/kg PO daily. Prednisone (1 mg/kg/day) may be useful to alleviate pruritus. Lomustine at 50 mg/m² PO q21–30 days may be effective (White 2005c)
- g) For systemic histiocytosis: lomustine at 70 mg/m² PO every 3 weeks; cyclosporine 5–10 mg/kg once daily (q24h); prednisone 2 mg/kg PO q12–24h. (Hillier 2006d)
- h) For canine cutaneous epitheliotropic lymphoma (ELSA): 60 mg/m² PO every three weeks. Authors concluded that lomustine seemed to be safe and well tolerated. Response duration was short, but high response rate supports incorporating lomustine into protocols to treat ELSA. Additional prospective investigations are warranted. (Risbon, de Lorimeir et al. 2006)
- i) For brain tumors: Initially, 60 mg/m² PO; if toxicity is minimal the dosage is increased slowly to 80 mg/m². Treatments given every 5–8 weeks. CBC done every week between treatments. (Fulton 1991)

■ CATS:

For the treatment of neoplasms:

- a) 60 mg/m² PO q6 weeks (Brewer 2003)
- b) 60 mg/m² PO q6 weeks or 10 mg (total dose) PO every three weeks. (Kitchell 2005)

Monitoring

- CBC with platelets one week after dosing and prior to next dose; If platelets less than 200,000/mcL; stop therapy until thrombocytopenia is resolved
- Liver function tests; initially before starting treatment and then every 3–4 months

Chemistry/Synonyms

A nitrosourea derivative alkylating agent, lomustine occurs as a yellow powder that is practically insoluble in water and soluble in alcohol.

Lomustine may also be known as: CCNU, lomustinum, NSC-79037, RB-1509, WR-139017, *Belustine*®, *CCNU*®, *Cecenu*®, *CeeNu*®, *CiNU*®, *Citosta*®, *Lomeblastin*®, *Lucostin*®, *Lucostine*®, and *Prava*®.

Storage/Stability

Store capsules in well-closed containers at room temperature. Expiration dates of two years are assigned after manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Lomustine Capsules: 10 mg, 40 mg & 100 mg with mannitol; Dose Pack (two 100 mg capsules, two 40 mg capsules and two 10 mg capsules); *CeeNu*® (Bristol Labs Oncology); (Rx)

LOPERAMIDE HCL

(loe-*per*-a-mide) Imodium®

OPIATE ANTIDIARRHEAL

Prescriber Highlights

- Synthetic opiate GI motility modifier
- Contraindications: Known hypersensitivity to narcotic analgesics, diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract
- Caution: Respiratory disease, hepatic encephalopathy, hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), head injuries, or increased intracranial pressure, & acute abdominal conditions (e.g., colic), & in geriatric or severely debilitated patients; use loperamide cautiously in Collie-type breeds
- Adverse Effects: **DOGS:** Constipation, bloat, & sedation. Potential for: paralytic ileus, toxic megacolon, pancreatitis, & CNS effects. **CATS:** Use is controversial, may exhibit excitatory behavior.
- Dose carefully in small, small animals

Uses/Indications

Loperamide is used as a GI motility modifier in small animals. Use in cats is controversial and many clinicians do not recommend using in cats.

Pharmacology/Actions

Among their other actions, opiates inhibit GI motility and excessive GI propulsion. They also decrease intestinal secretion induced by cholera toxin, prostaglandin E₂ and diarrheas caused by factors in which calcium is the second messenger (non-cyclic AMP/GMP mediated). Opiates may also enhance mucosal absorption.

Pharmacokinetics

In dogs, loperamide reportedly has a faster onset of action and longer duration of action than diphenoxylate, but clinical studies confirming this appear to be lacking. In humans, loperamide's half-life is about 11 hours. It is unknown if the drug enters milk or crosses the placenta.

Contraindications/Precautions/Warnings

All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency, (Addison's), and in geriatric or severely debilitated patients.

Opiate antidiarrheals should be used with caution in patients with head injuries or increased intracranial pressure and acute abdominal conditions (e.g., colic), as it may obscure the diagnosis or clinical course of these conditions. It should be used with extreme caution in patients suffering from respiratory disease or from acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation). Opiate antidiarrheals should be used with ex-

treme caution in patients with hepatic disease with CNS clinical signs of hepatic encephalopathy. Hepatic coma may result.

Many clinicians recommend not using diphenoxylate or loperamide in dogs weighing less than 10 kg, but this is probably a result of the potency of the tablet or capsule forms of the drugs. Dosage titration using the liquid forms of these agents should allow their safe use in dogs when indicated. Because loperamide is potentially a neurotoxic substrate of P-glycoprotein, it should be used with caution in those herding breeds (e.g., Collies, Shelties, Australian shepherds, etc.) that may have the gene mutation that causes a non-functional protein.

Adverse Effects

In dogs, constipation, bloat, and sedation are the most likely adverse reactions encountered when usual doses are used. Potentially, paralytic ileus, toxic megacolon, pancreatitis, and CNS effects could be seen.

Use of antidiarrheal opiates in cats is controversial; this species may react with excitatory behavior.

Reproductive/Nursing Safety

In humans, the FDA categorizes loperamide as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether loperamide is excreted in maternal milk. Safety during nursing has not been established.

Overdosage/Acute Toxicity

In dogs, doses of 1.25 to 5 mg/kg/day produced vomiting, depression, severe salivation, and weight loss. Breeds with a defective MDR-1 gene are more sensitive to CNS depression with loperamide than other breeds.

There were 903 exposures to loperamide reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2000–2006. In these cases 862 were dogs with 395 showing clinical signs and 33 cats with 11 showing clinical signs. The remaining cases were 3 rodents, 4 birds and 1 rabbit, none of which showed clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, lethargy, diarrhea, depression, hypersalivation, hypothermia, bradycardia and anorexia. Common findings in cats recorded in decreasing frequency included diarrhea, vomiting, anorexia, hypersalivation and vocalization.

Treatment should follow standard decontamination protocols. Naloxone may be used to treat severe effects; higher than usual doses may be required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving loperamide and may be of significance in veterinary patients:

- **AMIODARONE:** By inhibiting P-gp may increase loperamide plasma concentrations
- **CARVEDILOL:** By inhibiting P-gp may increase loperamide plasma concentrations
- **ERYTHROMYCIN:** By inhibiting P-gp may increase loperamide plasma concentrations
- **KETOCONAZOLE, ITRACONAZOLE:** By inhibiting P-gp may increase loperamide plasma concentrations
- **QUINIDINE:** By inhibiting P-gp may increase loperamide plasma concentrations

■ **TAMOXIFEN:** By inhibiting P-gp may increase loperamide plasma concentrations

■ **VERAPAMIL:** By inhibiting P-gp may increase loperamide plasma concentrations

Laboratory Considerations

- Plasma **amylase** and **lipase** values may be increased for up to 24 hours following administration of opiates.

Doses

■ DOGS:

As an antidiarrheal:

Note: Collies and related breeds may be overly sensitive to loperamide

- a) 0.08 mg/kg, PO three times daily (DeNovo 1988), (Washabau 2004)
- b) 0.1–0.2 mg/kg PO q8–12h (Willard 2003a)
- c) 0.1 mg/kg PO three times a day; probably should not be given longer than 5 days and is potentially contraindicated when diarrhea is suspected to be caused by enteric infections (Hall and Simpson 2000)
- d) 0.1–0.2 mg/kg PO q8h (Jergens 1995)
- e) 0.08 mg/kg PO 3–4 times a day (Cote 2000)
- f) 0.1–0.2 mg/kg PO q6–12h (Leib 2004b)

■ CATS:

Note: Use of antidiarrheal opiates in cats is controversial; this species may react with excitatory behavior.

- a) For Diarrhea: Using the suspension 0.04–0.06 mg/kg PO twice daily (Tams 1999)
- b) 0.08–0.16 mg/kg PO q12h (Willard 2003a)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 0.1 mg/kg in 1 mL of water PO q8h for 3 days, then once daily for 2 days (Ivey and Morrissey 2000)
- b) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 0.1 mg/kg PO q8h for 3 days, then once daily for 2 days; give in 1 mL of water (Adamcak and Otten 2000)

Monitoring

- Clinical efficacy
- Fluid and electrolyte status in severe diarrhea
- CNS effects if using high dosages

Client Information

- If diarrhea persists or if animal appears listless or develops a high fever, contact veterinarian.

Chemistry/Synonyms

A synthetic piperidine-derivative antidiarrheal, loperamide occurs as a white to faintly yellow powder with a pK_a of 8.6 that is soluble in alcohol and slightly soluble in water.

Loperamide may also be known as PJ 185, or R 18553; a common trade name is *Imodium*®.

Storage/Stability/Compatibility

Loperamide capsules or oral solution should be stored at room temperature in well-closed containers. It is recommended that the oral solution not be diluted with other solvents.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Loperamide HCl Oral Liquid: 1 mg/5 mL (0.2 mg/mL), 1 mg/7.5 mL and 1 mg/mL in 60 mL, 90 mL, 118 mL and 120 mL; *Imodium® A-D* (McNeil-CPC); *Pepto® Diarrhea Control* (Procter and Gamble); generic; (OTC)

Loperamide HCl Capsules and Tablets: 2 mg; *Imodium® A-D Caplets* (McNeil-CPC); *Neo-Diarral®* (Roberts); *K-Pek II®* (Rugby); generic; (OTC & Rx)

LORAZEPAM

(lor-ayz-eh-pam) Ativan®

BENZODIAZEPINE

Prescriber Highlights

- ▶ Benzodiazepine that can be useful as an anxiolytic in dogs & cats & as an alternative to diazepam for treating status epilepticus
- ▶ Can be administered intranasally or IV for status epilepticus
- ▶ Adverse Effects (most likely): Increased appetite, activity or behavior changes (lethargy/somnolence to hyperexcitability/aggression)

Uses/Indications

Lorazepam may be useful in treating status epilepticus in dogs and the adjunctive treatment of behavior disorders (fears, phobias, anxiety) in dogs and cats. Although, in veterinary medicine, when compared with diazepam, there is much less experience using lorazepam, it has some advantages. Lorazepam is not metabolized by the liver into active metabolites, appears as effective as diazepam, may have longer anticonvulsant duration of action (not proven in dogs), and can be easier to administer (intranasal, IM, sublingual/buccal).

In human medicine, lorazepam is now frequently used in place of diazepam for treating status epilepticus and anxiolytic indications. It is also used for treating cancer chemotherapy-induced nausea and emesis, alcohol withdrawal, and akathisia secondary to antipsychotic medications.

Pharmacology/Actions

Lorazepam and other benzodiazepines depress the subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS thus producing anxiolytic, sedative, skeletal muscle relaxant, and anticonvulsant effects. The exact mechanism of action is unknown, but postulated mechanisms include: antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. Receptors are lacking in the white matter. In all species studied.

Pharmacokinetics

In dogs, intravenous administration of 0.2 mg/kg gave peak levels of about 165 ng/mL and remained above 30 ng/mL (considered necessary for anticonvulsant activity in humans) for 60 minutes. After intranasal administration of 0.2 mg/kg to dogs (Mariani, Clemmons

et al. 2003), peak levels of about 106 ng/mL were achieved; in 3/6 dogs studied, levels stayed above 30 ng/mL for 60 minutes. Levels reached 30 ng/mL between 3–9 minutes after intranasal administration. While elimination half-life has been reported as approximately 1 hour in dogs, concentrations in the brain may persist longer than in the serum as lorazepam has a high affinity for benzodiazepine receptors in the CNS. Rectal administration of lorazepam in dogs does not appear to yield serum concentrations high enough for efficacious treatment of status epilepticus due to a high first-pass effect. Lorazepam is converted into glucuronide forms in the liver in most species. These metabolites are not active. Primary elimination route is via the urine in dogs. In cats, elimination is approximately 50% in the urine (primarily as the glucuronide) and 50% in the feces.

In humans, absolute bioavailability is about 90% after oral administration and, unlike diazepam, it is relatively rapidly and completely absorbed after IM dosing. Sublingual administration has similar bioavailability as oral dosing, but serum levels peak sooner. Elimination half-life appears to be much longer in humans (12 hours) than in dogs (≈1 hour).

Contraindications/Precautions/Warnings

Lorazepam is contraindicated in patients known to be hypersensitive to benzodiazepines, or with severe respiratory insufficiency unless being mechanically ventilated.

When using for negative behaviors, withdraw the drug gradually or a rebound effect may occur. Physical dependency has been induced in dogs. If long-term regular usage has occurred, withdraw the drug gradually.

Injectable lorazepam must not be given intra-arterially; arteriospasm may occur resulting in necrosis.

Adverse Effects

In small animals, benzodiazepines can cause increased appetite, aggression, increased activity/excitement, and vocalization. With initiation of therapy, dosage increases, or at higher dosages, ataxia, somnolence and lethargy can occur.

Reproductive/Nursing Safety

For humans, lorazepam is designated by the FDA as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) However, studies in animals generally suggest that the drug is relatively safe for use during pregnancy at usual dosages. Except in one study in mice that were given approximately 400X the human dose producing offspring with an increased rate of cleft palate formation, animal studies have not shown significant increased rates of teratogenicity. If high doses are used just prior to delivery, “floppy infant” syndrome has been seen in humans.

Small amounts of lorazepam are distributed into milk, but it should be safe to use during nursing.

Overdosage/Acute Toxicity

Overdoses of lorazepam are generally limited to CNS depression (confusion, lethargy, somnolence, decreased reflexes, etc.). Very large overdoses can cause ataxia, hypotension, coma, and death (very rare).

Treatment of acute orally-ingested toxicity consists of standard protocols for removing and/or binding the drug in the gut and supportive systemic measures. In patients with normal renal function, forced diuresis with intravenous fluids/electrolytes and mannitol may enhance excretion of lorazepam. The use of analeptic agents (CNS stimulants such as caffeine) is generally not recommended. Flumazenil may be considered for adjunctive treatment of serious

overdoses of benzodiazepines, but its use does not replace proper supportive therapy. Flumazenil is not recommended in patients with seizure-disorders as it may induce seizures.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lorazepam and may be of significance in veterinary patients:

- **CNS DEPRESSANTS** (e.g., **opiates, barbiturates, sedatives, anticonvulsants**): Additive CNS effects
- **PROBENECID**: Decreased renal clearance of lorazepam
- **SCOPOLAMINE**: Increased CNS depression, irrational behavior
- **THEOPHYLLINE**: Decreased sedation from lorazepam
- **VALPROATE**: Increased lorazepam serum concentration

Laboratory Considerations

No specific concerns noted

Doses

■ DOGS/CATS:

- a) Dogs: as an alternative to diazepam for status epilepticus: 0.2 mg/kg IV, IM or intranasal once. (Hopper 2006a)
- b) For fears, anxieties, phobias: Dogs: 0.02–0.1 mg/kg PO once daily to three times a day; may be used on an as needed basis. Cats: 0.125 mg–0.25 mg (¼–½ of a 0.5 mg tablet) once a day to twice a day; may be used on an as needed basis. (Landsberg 2005b)
- c) As an anxiolytic: Dogs/Cats: 0.05–0.25 mg/kg PO q12–24h. (Virga 2005b)

Monitoring

- No specific monitoring is required beyond clinical efficacy and adverse effects

Client Information

- This medication may increase appetite, diligent food restriction may be required
- May cause changes in activity levels and can cause either lethargy or increased activity/excitement
- Do not stop treatment abruptly without veterinarian's guidance; animals receiving this medication on a regular basis for a prolonged period of time may develop withdrawal signs if not "weaned off" the drug
- Although liver toxicity has not yet been reported in animals receiving this medication, a drug (diazepam) similar to lorazepam has rarely caused liver toxicity in cats. If vomiting, lack of appetite, or yellowing of the whites of eyes or mucous membranes occur contact veterinarian immediately.
- Tablets are relatively tasteless and readily disintegrate in saliva. If pilling is difficult, place inside the patient's cheek and follow in a minute or so with a small treat to facilitate swallowing of saliva/medication.

Chemistry/Synonyms

Lorazepam occurs as a white or practically white, practically odorless powder. It is insoluble in water and sparingly soluble in alcohol.

Lorazepam may also be known as BRN-07599084, CB-8133, Ro-7-8408, Wy-4036, lorazepamum, anxiedin, azurogen, bonatranquan, delormetazepam, lorazin, lorazon, lorenin, norlormetazepam, novhepar, novolorazem, o-Chloroxazepam, sinestron, *Ativan*®, and *Lorazepam Intensol*®; many international trade names are available.

Storage/Stability/Compatibility

Lorazepam tablets should be stored in well-closed containers at room temperature (20–25°C). The oral solution and injection should be stored refrigerated (2–8°C) and protected from light.

The injection must be further diluted just prior before to intravenous injection with an equal volume of D5W, normal saline, or sterile water for injection. Do not shake the syringe vigorously, but gently invert repeatedly until the injection is diluted and completely mixed in solution. Do not use if solution is discolored or a precipitate forms. IV injections should be administered slowly, 2 mg over 2–5 minutes.

Although not part of the label information, lorazepam can be further diluted in D5W or NS for IV infusion. When used in this manner, lorazepam injection is most soluble in final concentrations from 0.1–0.2 mg/mL. For example, if using the 2 mg/mL injection, further dilution with 9 mL or 19 mL of D5W or NS would yield a final concentration of 0.2 or 0.1 mg/mL. The injection is very viscous; mix well before use. As precipitation/crystallization can occur, observe the solution before and during the infusion. D5W may be less prone to crystallization formation than is NS. Solutions for infusion mixed in this manner should be used within 12 hours of preparation.

Medications reported to be **compatible** (partial listing):

- **Syringe**: hydromorphone
- **Y-Site**: albumin, amikacin, amphotericin B cholesteryl, atracurium, cefotaxime, ciprofloxacin, cisplatin, dexamethasone, diltiazem, dobutamine, doxorubicin, famotidine, fentanyl, gentamicin, heparin, morphine, propofol, ranitidine, and vancomycin

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See appendix for more information.

HUMAN-LABELED PRODUCTS:

Lorazepam Tablets: 0.5, 1, & 2 mg; generic; (Rx; C-IV)

Lorazepam Concentrated Oral Solution: 2 mg/mL in 10 mL and 30 mL bottles with dropper (contains 0.6 g of PEG 400 in propylene glycol per mL of solution); *Lorazepam Intensol*® (Roxane); (Rx; C-IV)

Lorazepam Injection: 2 mg/mL and 4 mg/mL in 1 mL prefilled syringes, 1 mL single use vials and 10 mL multidose vials (contains 0.18 mL of PEG 400 in propylene glycol; 2% benzyl alcohol added as a preservative); *Ativan*® (Baxter), generic; (Rx; C-IV)

LUFENURON

(loo-fen-yur-on) Program®, Sentinel®

CHITIN SYNTHESIS INHIBITOR

Prescriber Highlights

- Used for flea control in dogs & cats; potentially an anti-fungal agent
- Adverse Effects: None at recommended doses

Uses/Indications

Lufenuron is approved for use in dogs and cats 6 weeks of age and older for the control of flea populations. The combination product of lufenuron and milbemycin (*Sentinel*®) is indicated for use in puppies and dogs 4 weeks and older for prevention and control of flea populations, prevention of heartworm disease, control of adult hookworms, and the removal and control of adult roundworms and whipworms.

Lufenuron showed initial promise as a treatment for fungal infections, but the early enthusiasm has dampened considerably as efficacy appears doubtful.

Pharmacology/Actions

Lufenuron acts by inhibiting chitin synthesis, polymerization, and deposition in fleas, thereby preventing eggs from developing into adults. It is believed that lufenuron's nonspecific effect on chitin synthesis is related to serine protease inhibition. Lufenuron's mechanism of action, theoretically, would also have effect on fungi.

Lufenuron does not kill adult fleas.

Pharmacokinetics

Approximately 40% of an oral dose is absorbed with the remainder eliminated in the feces. To maximize oral absorption, the manufacturer recommends administering in conjunction with or immediately after (within 30 minutes) a full meal. The drug is absorbed in the small intestine and stored in lipose tissue that acts as depot reservoir to slowly redistribute the drug back into the circulation. While the drug concentrates in the milk of lactating animals, it apparently does not cause ill effects in nursing animals.

After cats receive the injectable product, 2–3 weeks are required before blood levels attain effective concentrations. Cats require a substantially higher oral dosage per kg than do dogs for equivalent efficacy. The drug is apparently not metabolized, but excreted unchanged into the bile and eliminated in the feces.

Contraindications/Precautions/Warnings

The cat labeled injectable product should not be used in dogs; severe local reactions are possible.

Adverse Effects

Adverse effects reported in dogs and cats after oral lufenuron include: vomiting, lethargy/depression, pruritus/urticaria, diarrhea, dyspnea, anorexia, and reddened skin. The manufacturer reports that the adverse reaction rate is less than 5 animals in one million doses.

After receiving the injectable product, a small lump at the injection site has been noted in some cats. A few weeks may be required for this to dissipate.

Reproductive/Nursing Safety

The oral lufenuron products are considered safe to use in pregnant, breeding, or lactating animals; safety of the injectable product in reproducing cats has not been formally established at this time.

Overdosage/Acute Toxicity

Growing puppies were dosed at levels up to 30X for 10 months without overt effect on growth or viability noted. Cats receiving oral dosages of up to 17X apparently were unaffected.

Drug Interactions

Limited data available; the manufacturer states that when used with a variety of adulticides, vaccines, antibiotics, anthelmintics, and steroids no adverse effects or interactions were noted in either dogs or cats.

Doses

■ DOGS:

- For control of flea populations: See the label directions for *Program with Capstar* for using lufenuron with nitenpyram. For control of fleas, heartworm prevention, hookworm, ascarid or whipworms: see the label directions for Lufenuron/Milbemycin with Nitenpyram (*Sentinel*® and *Capstar*®—Novartis)
- For adjunctive therapy for dermatophytosis: 50–100 mg/kg PO once every 14 days for two treatments, then once a month until at least two negative fungal cultures are obtained (Mantousek 2003)

■ CATS:

- For control of flea populations: See the label directions *Program* and *Program with Capstar* for using lufenuron with or without nitenpyram.
- For adjunctive therapy for dermatophytosis: 50–100 mg/kg PO once every 14 days for two treatments, then once a month until at least two negative fungal cultures are obtained. (Mantousek 2003)

■ RABBITS/RODENTS/SMALL MAMMALS:

- Rabbits: 30 mg/kg PO every month (Ivey and Morrissey 2000)

Monitoring

- Efficacy

Client Information

- Must be used every 30 days to maximize efficacy.
- All animals in a household should be treated.
- Absorption of the drug is enhanced if given with a fatty meal. If animal vomits within 2 hours after dosing, the drug should be re-dosed. If a dose is missed, re-dose and then resume a monthly dosage regimen (dogs receiving the lufenuron/milbemycin product should be tested in 6 months or more for heartworm exposure with an antigen test).
- Do not split tablets.

Chemistry/Synonyms

A benzoylphenylurea derivative, lufenuron is classified as an insect development inhibitor. The drug is lipophilic.

Lufenuron may also be known as CGA-184699, *Capstar*®, *Program*® and *Sentinel*®.

Storage/Stability

The commercially available tablets and suspension should be stored at room temperature (15–30°C). The manufacturer states that intermittent exposure or exposure less than 48 hours to temperatures outside of storage recommendations for the tablets or suspension should not affect potency. Lufenuron tablets are assigned a 4 year expiration date after manufacture; the suspension 3 years after manufacture; and *Sentinel*® tablets 3 years after manufacture. Opened pouches of the suspension are not recommended for storage or use for the following dosing cycle.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Lufenuron Oral Suspension: in six tube packs; 135 mg (for cats up to 10 lb,—orange), 270 mg (for cats 11–20 lb,—green), cats over 20 lbs are provided the appropriate combination of packs.; *Program*® Suspension (Novartis); (Rx). Approved for use in cats and kittens (6 weeks of age or older).

Lufenuron 6 Month Injectable for Cats: 100 mg/mL in 10 syringe packages: 0.4 mL (40 mg) prefilled syringe (for cats up to 8.8 lb), 0.8 mL (80 mg) prefilled syringe (for cats 8.9–17.6 lb); *Program® 6 Month Injectable* (Novartis); (Rx). Approved for use in cats and kittens 6 weeks of age or older.

Lufenuron Oral Flavor Tabs for Dogs and Cats: For dogs up to 10 lb: 45 mg; For dogs 11 to 20 lb: 90 mg; For dogs 21 to 45 lb: 204.9 mg; For dogs 46 to 90 lb: 409.8 mg; Dogs over 90 lbs receive the appropriate combination of lufenuron tablets; For cats up to 6 lbs: 90 mg; 7–15 lb: 204.9 mg; cats over 15 lb: receive the appropriate combination of lufenuron tablets *Program® Flavor Tabs* (Novartis); (OTC). Approved for use in dogs, puppies, cats, & kittens (4 weeks of age or older).

Lufenuron and Nitenpyram Oral Tablets for Dogs: For dogs up to 10 lb: 45 mg Lufenuron, 11.4 mg nitenpyram; For dogs 11 to 20 lb: 90 mg lufenuron, 11.4 mg nitenpyram; For dogs 21 to 25 lb: 204.9 mg lufenuron, 11.4 mg nitenpyram; For dogs 26 to 45 lb: 204.9 mg lufenuron, 57 mg nitenpyram; For dogs 46 to 90 lb: 409.8 mg lufenuron, 57 mg nitenpyram; Dogs over 90 lbs receive the appropriate combination of Lufenuron tablets and 57 mg nitenpyram tablets; *Program® Flavor Tabs* and *Capstar® Flea Management System for Dogs* (Novartis); (OTC). Approved for use in dogs and puppies (6 weeks of age or older).

Lufenuron and Nitenpyram Oral Tablets for Cats: For cats 2 to 6 lb: 90 mg lufenuron, 11.4 mg nitenpyram; For cats 7 to 15 lb: 204.9 mg lufenuron, 11.4 mg nitenpyram; For cats 16 to 25 lb: appropriate combination of tabs provided lufenuron, 11.4 mg nitenpyram; *Program® Flavor Tabs* (OTC); and *Capstar® Flea Management System for Cats* (Novartis); (OTC)

Milbemycin/Lufenuron Oral Tablets with Nitenpyram Oral Tablets for Dogs: For dogs 2 to 10 lb: 46 mg milbemycin/Lufenuron, 11.4 mg nitenpyram; For dogs 11 to 25 lb: 115 mg milbemycin/lufenuron, 11.4 mg nitenpyram; For dogs 26–50 lb: 230 mg milbemycin/lufenuron, 57 mg nitenpyram; For dogs 51 to 100 lb: 460 mg milbemycin/lufenuron, 57 mg nitenpyram; For dogs 100 to 125 lb: (appropriate number supplied) milbemycin/lufenuron, 57 mg nitenpyram; *Sentinel® Flavor Tabs with Capstar®* (Novartis); (Rx). Approved for use in dogs and puppies 4 weeks of age or older.

HUMAN-APPROVED PRODUCTS: None

LYSINE L-LYSINE

(lye-seen)

NUTRITIONAL AMINO ACID

Prescriber Highlights

- ▶ Amino acid that may be effective in suppressing FHV-1 infections in cats
- ▶ Adverse effects unlikely if mixed with food
- ▶ Long-term treatment required

Uses/Indications

Lysine may be effective in suppressing FHV-1 infections in cats.

Pharmacology/Actions

Lysine is an amino acid that is thought to compete with arginine for incorporation into many herpes viruses. As it is believed that arginine is required for producing infective viral particles, when lysine is incorporated, the virus becomes less infective.

Pharmacokinetics

No specific information was located.

Contraindications/Precautions/Warnings

No specific contraindications.

Adverse Effects

Adverse effects are unlikely when mixed with food. Patients (human) taking lysine have occasionally complained of abdominal pain and diarrhea; one patient developing tubulointerstitial nephritis has been reported.

Reproductive/Nursing Safety

Lysine showed no teratogenic effects when given to pregnant rats, although safety has not been established in other species.

Overdosage/Acute Toxicity

Significant toxicity is unlikely. Gastrointestinal effects (nausea, vomiting, diarrhea) may occur.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving lysine and may be of significance in veterinary patients:

- **ARGININE:** Arginine may negate the anti-herpesvirus effects of lysine
- **CALCIUM, ORAL:** Concomitant use with calcium supplements may increase calcium absorption from the gut and decrease calcium loss in the urine

Laboratory Considerations

No specific concerns noted

Doses

■ CATS:

To prevent or reduce recurrent feline herpesvirus ocular infections:

- a) 500 mg PO twice daily for life (Glaze 2002)
- b) 500 mg mixed with food daily (Nasisse 2002)
- c) 250 mg PO twice daily (Powell 2002), (August 2007)

As adjunctive therapy for feline herpesvirus dermatologic infections:

- a) 250 mg PO twice daily (Griffies 2002)
- b) 250 mg PO once to twice daily (Boord 2002)

Monitoring

- No specific monitoring is required for lysine except those that would be required to monitor the herpes infection in the patient.

Client Information

- Lysine is easiest to administer by crushing tablets or emptying capsules and then mixing with food.
- Clients should understand that lysine does not cure the infection, but helps to control it (reduces the severity and frequency) and that lifetime therapy may be required.

- When purchasing, avoid products that contain propylene glycol.

Chemistry/Synonyms

An aliphatic amino acid, lysine has the chemical name L-2,6-diaminohexanoic acid and has a molecular weight of 146.2. It may be commercially available as the acetate or hydrochloride salts, or as the base.

Lysine may also be known as: L-lysine, *L-Lysine Powder-Pure*®, Lys, K, *Enisyl*®, *Incremin*®, and *Viralys*®.

Storage/Stability

Unless otherwise specified on the label, lysine should be stored at room temperature in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Note: There are many products containing lysine as one of many ingredients. The following products were located with veterinary labeling where lysine is sole active ingredient:

L-lysine Gel: 250 mg per 1.25 mL: *Viralys*® Gel (Vet Solutions); (OTC). Labeled for use in cats and kittens.

L-lysine Powder: (in a palatable base) approximately 250 mg per rounded scoop: *Viralys*® Powder (Vet Solutions); (OTC). Labeled for use in cats and kittens.

L-Lysine Powder Feed Additive: in 16 oz. jars and 5 lb. pails; *L-Lysine Powder-Pure*® (AHC); (OTC) Labeled for use in horses.

HUMAN-LABELED PRODUCTS:

L-Lysine Tablets & Capsules: 312 mg, 334 mg, 500 mg & 1000 mg; *Enisyl*® (Person & Covey); generic; (OTC)

Lysine is considered a nutrient in the USA, therefore, it is exempt from FDA approval requirements. There are many products available including tablets and capsules that usually range in strengths from 250 mg to 1000 mg. Combination products are also available.

Lysodren® — see Mitotane

Magnesium-containing Laxatives – see **Saline/Hyperosmotic Laxatives; Magnesium Hydroxide**

MAGNESIUM HYDROXIDE MAGNESIUM/ALUMINUM ANTACIDS

(mag-*nee*-zee-um hye-*droks*-ide)

ORAL ANTACID/LAXATIVE

Prescriber Highlights

- Used as a gastric antacid for ulcers, etc., but use largely supplanted by newer agents
- In ruminants, can be useful to increase rumen pH
- Magnesium salts contraindicated in patients with renal disease
- Magnesium salts may cause diarrhea
- Chronic use may lead to electrolyte abnormalities
- Many potential drug interactions

Uses/Indications

Magnesium hydroxide in combination with aluminum salts have been used in veterinary medicine for the adjunctive treatment of esophagitis, gastric hyperacidity, peptic ulcer and gastritis. In foals and small animals, because of difficulty in administration, the frequent dosing that is often required, and availability of the histamine-2 blocking agents (cimetidine, ranitidine, etc.), proton-pump inhibitors (e.g., omeprazole) and sucralfate, antacids have largely been relegated to adjunctive roles in therapy for these indications. Magnesium hydroxide alone (milk of magnesia) is sometimes used as an oral laxative in small animals.

In ruminants, magnesium hydroxide is used to increase rumen pH and as a laxative in the treatment of rumen overload syndrome (*aka* acute rumen engorgement, rumen acidosis, grain overload, engorgement toxemia, rumen impaction).

Pharmacology/Actions

Oral antacids used in veterinary medicine are generally relatively non-absorbable salts of aluminum, calcium or magnesium. Up to 20% of an oral dose of magnesium can be absorbed, however. Antacids decrease HCl concentrations in the GI. One gram of these compounds generally neutralizes 20–35 mEq of acid (*in vitro*). Although the pH of the gastric fluid can rarely be brought to near-neutral conditions, at a pH of 3.3, 99% of all gastric acid is neutralized, thereby reducing gastric acid back-diffusion through the gastric mucosa and reducing the amount of acid presented to the duodenum. Pepsin proteolytic activity is reduced by raising the pH and can be minimized if the pH of the gastric contents can be increased to >4.

Contraindications/Precautions/Warnings

Magnesium-containing antacids are contraindicated in patients with renal disease. Some products have significant quantities of sodium or potassium and should be used cautiously in patients who should have these electrolytes restricted in their diet. Aluminum-containing antacids may inhibit gastric emptying; use cautiously in patients with gastric outlet obstruction.

Adverse Effects

In monogastric animals, the most common side effects of antacid therapy are constipation with aluminum- and calcium-containing antacids, and diarrhea or frequent loose stools with magnesium-containing antacids. Many products contain both aluminum and magnesium salts in the attempt to balance the constipating and laxative actions of the other.

If the patient is receiving a low phosphate diet, hypophosphatemia can develop if the patient chronically receives aluminum antacids. Magnesium-containing antacids can cause hypermagnesemia in patients with severe renal insufficiency.

If administering calcium carbonate in high doses or chronically, significant quantities of calcium can be absorbed from the gut resulting in hypercalcemia in susceptible patients. Calcium carbonate has also been implicated in causing a gastric acid rebound phenomena. Patients with significant renal impairment or dehydration and electrolyte imbalance can develop the milk-alkali syndrome. If the patient is receiving a low phosphate diet, hypophosphatemia can develop if the patient chronically receives calcium carbonate antacids.

In ruminants, alkalinization of the rumen may enhance the absorption of ammonia, histamine or other basic compounds.

Reproductive/Nursing Safety

In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), these drugs are categorized as class: A (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Overdosage/Acute Toxicity

See the Adverse Effects section above. If necessary, GI and electrolyte imbalances that can occur with chronic or acute overdose should be treated symptomatically.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral magnesium hydroxide and may be of significance in veterinary patients:

- **QUINIDINE:** Increased absorption or pharmacologic effect may occur
- **SODIUM POLYSTYRENE SULFONATE** (*Kayexalate*®): Antacids may decrease the potassium lowering effectiveness of the drug and in patients in renal failure may cause metabolic alkalosis
- **SUSTAINED- or EXTENDED-RELEASE MEDICATIONS:** When magnesium hydroxide is used at laxative dosages, it may alter the absorption of these drugs by altering GI transit times
- **SYMPATHOMIMETIC AGENTS:** Increased absorption or pharmacologic effect may occur

Oral magnesium salts can **decrease** the amount absorbed or the pharmacologic effect the drugs listed below; separate oral doses of magnesium hydroxide and these drugs by two hours to help reduce this interaction.

- **ALLOPURINOL**
- **AZOLE ANTIFUNGALS** (*Ketoconazole, Itraconazole*)
- **CHLOROQUINE**
- **CORTICOSTEROIDS**
- **DIGOXIN**
- **ETHAMBUTOL**
- **FLUOROQUINOLONES**
- **H-2 ANTAGONISTS** (*Ranitidine, Famotidine, etc.*)
- **IRON SALTS**
- **ISONIAZID**
- **PENICILLAMINE**
- **PHENOTHIAZINES**
- **TETRACYCLINES**
- **THYROID HORMONES**

Doses**■ DOGS:**

For adjunctive therapy for gastric ulcers:

- a) Aluminum hydroxide suspension or aluminum hydroxide/magnesium hydroxide suspension: 2–10 mL PO q2–4h (Hall and Twedt 1988)

As an antacid:

- a) Magnesium hydroxide (Milk of Magnesia): 5–30 mL PO once to twice daily (Morgan 1988)

■ CATS:

As an antacid:

- a) Magnesium hydroxide (Milk of Magnesia): 5–15 mL PO once to twice daily (Morgan 1988)

■ CATTLE:

For rumen overload syndrome:

- a) For adult animals: Up to 1 gm/kg (MgOH) mixed in 2–3 gallons of warm water and given PO per tube. May repeat (use smaller doses) at 6–12 hour intervals. If the rumen has been evacuated, do not exceed 225 grams initially. Dehydration and systemic acidosis must be concomitantly corrected.
- b) Calves: As above but use 1/8th–1/4th the amount (Wass et al. 1986a)

■ HORSES:

For adjunctive gastroduodenal ulcer therapy in foals:

- a) Aluminum/magnesium hydroxide suspension: 15 mL 4 times a day (Clark and Becht 1987)

■ SHEEP & GOATS:

For rumen overload syndrome:

- a) As above for cattle, but use 1/8th–1/4th the amount (Wass et al. 1986a)

Monitoring

- Monitoring parameters are dependent upon the indication for the product. Patients receiving high dose or chronic therapy should be monitored for electrolyte imbalances outlined above.

Client Information

- Oral magnesium hydroxide products are available without prescription (OTC); do not give on a regular basis without veterinary supervision

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Oral Boluses 17.9–27 grams of magnesium hydroxide (**Note:** products may also contain ginger, capsicum and methyl salicylate); *Magnalax*® (Aspen), *Carmilax*® (Pfizer), *Polymag*® (Butler), *Rumen Bolus*® (Durvet), *Instamag*® (Vedco), *Magnalax*® (Phoenix), *Polyox-II* (Bimeda), *Laxade*® (AgriPharm); (OTC)

Oral Powder, each pound of powder contains: 350–361 grams of magnesium hydroxide (**Note:** products may also contain ginger, capsicum and methyl salicylate); *Carmilax Powder*® (Pfizer), *Magnalax*® (Phoenix), *Polyox*® (Bimeda), *Laxade*® (AgriPharm); (OTC)

Milk of Magnesia (Magnesium Hydroxide) 80 mg/mL in gallons; generic, (Neogen); (OTC)

HUMAN-LABELED PRODUCTS:

The following is a list of some magnesium hydroxide products available, it is not meant to be all-inclusive.

Magnesium Hydroxide

Tablets chewable: 311 mg *Phillips' Chewable*® (Sterling Health)

Liquid: 400 mg/5 mL in 360 mL, pt and gal and UD 15 and 30 mL; 800 mg/5 mL in 240 mL; *Phillips' Milk of Magnesia*® (Sterling Health), *Concentrated Phillips' Milk of Magnesia*® (Sterling Health), etc.

Aluminum Hydroxide and Magnesium Hydroxide

Suspension (**Note:** There are too many products and concentrations to list in this reference; a representative product is *Maalox® Suspension* (Rorer) which contains 225 mg aluminum hydroxide and 200 mg magnesium hydroxide per 5 mL.)

All aluminum and magnesium hydroxide preparations are OTC. Other dosage forms that are available commercially include: tablets, chewable tablets, and aerosol foam suspension.

MAGNESIUM MAGNESIUM SULFATE, PARENTERAL MAGNESIUM CHLORIDE, PARENTERAL

(mag-nee-zee-um)

PARENTERAL ELECTROLYTE

For information on the use of oral magnesium hydroxide, refer to the previous monograph. Magnesium oxide and oral magnesium sulfate are also detailed in the monograph for Saline/Hyperosmotic laxatives.

Prescriber Highlights

- ▶ Parenteral electrolyte for hypomagnesemia, for adjunctive therapy of malignant hyperthermia in swine, as an anticonvulsant, & for refractory ventricular arrhythmias
- ▶ Contraindications: Significant myocardial damage or heart block
- ▶ Caution: Impaired renal function
- ▶ Adverse Effects: Usually as a result of OD (drowsiness or other CNS depressant effects, muscular weakness, bradycardia, hypotension, respiratory depression, & increased Q-T intervals on ECG). Very high levels: Neuromuscular blocking activity &, eventually, cardiac arrest
- ▶ Must monitor to avoid hypermagnesemia
- ▶ Do not confuse mEq/mL & mg/mL concentrations & dosages

Uses/Indications

Parenteral magnesium sulfate is used as a source of magnesium in magnesium deficient states (hypomagnesemia), for adjunctive therapy of malignant hyperthermia in swine, and also as an anticonvulsant. It may be of benefit in the treatment of refractory ventricular fibrillation.

Pharmacology/Actions

Magnesium is used as a cofactor in a variety of enzyme systems and plays a role in muscular excitement and neurochemical transmission.

Pharmacokinetics

IV magnesium results in immediate effects; IM administration may require about 1 hour for effect. Magnesium is about 30–35% bound to proteins and the remainder exists as free ions. It is excreted by the kidneys at a rate proportional to the serum concentration and glomerular filtration.

Contraindications/Precautions/Warnings

Parenteral magnesium is contraindicated in patients with myocardial damage or heart block. Magnesium should be given with caution to patients with impaired renal function. Patients receiving parenteral magnesium should be observed and monitored carefully to avoid hypermagnesemia.

Adverse Effects

Magnesium sulfate (parenteral) adverse effects are generally the result of magnesium overdosage and may include drowsiness or other CNS depressant effects, muscular weakness, bradycardia, hypotension, hypocalcemia, respiratory depression and increased Q-T intervals on ECG. Very high magnesium levels may cause neuromuscular blocking activity and, eventually, cardiac arrest.

When using IV for hypomagnesemia, reduce potassium supplementation or hyperkalemia may result.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) The possibility of fetal harm appears remote; however, use only if clearly needed.

Magnesium is excreted in milk, but is unlikely to pose significant risk to nursing offspring.

Overdosage/Acute Toxicity

See Adverse Effects above. Treatment of hypermagnesemia is dependent on the serum magnesium level and any associated clinical effects. Ventilatory support and administration of intravenous calcium [10–50 mg/kg IV; (Macintire 2003)] may be required for severe hypermagnesemia.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving parenteral magnesium sulfate or HCl and may be of significance in veterinary patients:

- **CALCIUM:** Concurrent use of calcium salts may negate the effects of parenteral magnesium
- **CNS DEPRESSANT DRUGS** (e.g., barbiturates, general anesthetics): Additive CNS depression may occur.
- **DIGOXIN:** Because serious conduction disturbances can occur, parenteral magnesium should be used with extreme caution with digitalis cardioglycosides
- **NEUROMUSCULAR BLOCKING AGENTS:** Excessive neuromuscular blockade possible

Doses

Note: Do not confuse mEq/mL and mg/mL concentrations and dosages; One gram of magnesium sulfate hexahydrate contains 8.1 mEq of magnesium. Magnesium chloride contains 9.25 mEq of magnesium per gram.

■ DOGS & CATS:

For hypomagnesemia:

- a) Use magnesium sulfate as an IV CRI at 1 mEq/kg/24 hours; often seen in refractory hypokalemic patients (Reiser 2006)
- b) 0.75–1 mEq/kg/day administered by a constant rate infusion in D5W. Concentrate should be diluted to at least 20%. A lower dose of 0.3–0.5 mEq/kg/day may be used for an additional 3–5 days as complete repletion occurs slowly. (Holland and Chastain 1995)
- c) For chronic hypomagnesemia (once parenteral repletion has occurred): Using oxide or hydroxide salts, 1–2 mEq/kg/day PO. Diarrhea may occur. (Fascetti 2003)
- d) For hypomagnesemia associated with diabetic ketoacidosis in cats: Total magnesium concentrations of less than 1.5 mg/dL should be treated with magnesium sulfate as an IV CRI of 0.5–1 mEq/kg administered over 24 hours. (Waddell 2007b)

For refractory ventricular arrhythmias:

- Magnesium sulfate: 30 mg/kg slowly IV (**Note:** This converts to a dose of 0.243 mEq/kg—Plumb) (Macintire 2006a)
- If needed for life-threatening ventricular arrhythmias: 0.15–0.3 mEq/kg may be administered over 5–15 minutes. (Holland and Chastain 1995)

■ HORSES:

For VTach:

- 4 mg/kg IV boluses every 2 minutes or a 2 mg/kg/min IV infusion to a total dose of 50 mg/kg (**Note:** Do not use magnesium plus calcium containing solutions) (Mogg 1999)

For adjunctive treatment of perinatal asphyxia syndrome in foals:

- Magnesium sulfate 50 mg/kg diluted to 1% and given IV over one hour, then decrease to 25 mg/kg/hr as a constant rate infusion for 24 hours (Vaala 2003b)
- as above in “a”, but after the first hour: 25 mg/kg/hr CRI for 1–3 days. (Bentz 2006b)

■ RUMINANTS:

For hypomagnesemia (grass and other magnesium-related tetanies):

- Cattle: Magnesium sulfate 20–50%: 200 mL SC, followed by a slow IV infusion of 500 mL of a calcium/magnesium solution (Calcium borogluconate 23%; MgCl₂ 6%) (Phillips 1988a)
- Cattle: 350 mL (250 mL of 25% calcium borogluconate and 100 mL of 10% of magnesium sulfate) by slow IV. If not a proprietary mixture, give calcium first. Relapses occur frequently after IV therapy, and 350 mL SC of magnesium sulfate 20% may give more sustained magnesium levels. Alternating calcium and magnesium may prevent adverse effects. Continue control measures for 4–7 days to prevent relapse.
- Sheep and Goats: 50–100 mL of above solution (calcium/magnesium).

For whole milk tetany in calves 2–4 months of age:

- Magnesium sulfate 10% 100 mL; followed by oral magnesium oxide at daily doses of 1 gram PO (0–5 weeks old), 2 gram PO (5–10 weeks old), and 3 grams PO (10–15 weeks old) (Merrall and West 1986)

■ SWINE:

For adjunctive therapy of malignant hyperthermia syndrome:

- Magnesium sulfate 50%: Incremental doses of 1 gram injected slowly IV until heart rate and muscle tone are reduced. Use calcium if magnesium-related cardiac arrest occurs (Booth 1988)

Monitoring

- Toxicity, including serum magnesium
- Physical signs associated with hypomagnesemia
- Serum calcium, potassium if indicated

Chemistry/Synonyms

Magnesium sulfate occurs as small, usually needle-like, colorless crystals with a cool, saline, bitter taste. It is freely soluble in water and sparingly soluble in alcohol. Magnesium sulfate injection has a pH of 5.5–7. One gram of magnesium sulfate hexahydrate contains 8.1 mEq of magnesium. Magnesium chloride contains 9.25 mEq of magnesium per gram.

Magnesium Sulfate may also be known as: 518, epsom salts, magnesii sulfas, magnesium sulfuric heptahydricum, magnesium sulphate, sal amarum, sel anglais, and sel de sedlitz; many trade names are available.

Storage/Stability/Compatibility

Magnesium sulfate and magnesium chloride for injection should be stored at room temperature (15–30°C); avoid freezing. Refrigeration may result in precipitation or crystallization.

Magnesium sulfate is reportedly physically **compatible** with the following intravenous solutions: dextrose 5%, LRS, and Normal saline. It is also **compatible** with calcium gluconate, cephalothin sodium, chloramphenicol sodium succinate, cisplatin, hydrocortisone sodium succinate, isoproterenol HCl, methyldopate HCl, metoclopramide HCl (in syringes), norepinephrine bitartrate, penicillin G potassium, potassium phosphate, and verapamil HCl. Additionally, at Y-sites: acyclovir sodium, amikacin sulfate, ampicillin sodium, carbenicillin disodium, cefamandole nafate, cefazolin sodium, cefoperazone sodium, ceforanide, cefotaxime sodium, ceftiofur sodium, cephalothin sodium, cephapirin sodium, clindamycin phosphate, doxycycline phosphate, erythromycin lactobionate, esmolol HCl, gentamicin sulfate, heparin sodium, kanamycin sulfate, labetalol HCl, metronidazole (RTU), moxalactam disodium, nafcillin sodium, oxacillin sodium, piperacillin sodium, potassium chloride, tetracycline HCl, ticarcillin disodium, tobramycin sulfate, trimethoprim/sulfamethoxazole, vancomycin HCl, and vitamin B-complex with C.

Magnesium sulfate is reportedly physically **incompatible** when mixed with alkali hydroxides, alkali carbonates, salicylates and many metals, including the following solutions or drugs: fat emulsion 10 %, calcium gluceptate, dobutamine HCl, polymyxin B sulfate, procaine HCl, and sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

There are no parenteral magnesium-only products approved for veterinary medicine. There are, however, several proprietary magnesium-containing products available that may also include calcium, phosphorus, potassium, and/or dextrose; refer to the individual product's labeling for specific dosage information. Trade names for these products include: *Norcalciphos*® (Pfizer); *Cal-Dextro*® *Special*, and #2 (Fort Dodge); and *CMPK*®; and *Cal-Phos*® #2 (TechAmerica). They are legend (Rx) drugs.

HUMAN-LABELED PRODUCTS:

Magnesium Sulfate Injection: 10% (0.8 mEq/mL), 12.5% (1 mEq/mL), and 50% (4 mEq/mL) in 2 mL, 10 mL and 20 mL amps, 2 mL fill in 5 mL vials, 2 mL, 5 mL, 10 mL, 20 mL and 50 mL vials and multi-dose vials and 5 and 10 mL disposable syringes; generic; (Rx)

Magnesium Chloride Injection: 20% (1.97 mEq/mL) in 50 mL multi-dose vials; 10% (0.8 mEq/mL) in 20 mL, 50 mL vials & 20 mL amps; 12.5% (1 mEq/mL) in 20 mL vials; 50% (4 mEq/mL) in 2 mL, 5 mL, 10 mL, 20 mL & 50 mL vials, 5 mL & 10 mL syringes, & 2 mL & 10 mL amps; generic; (Rx)

There are many oral magnesium products in various dosage forms available.

MANNITOL

(*man-i-tole*)

OSMOTIC DIURETIC

Prescriber Highlights

- ▶ Osmotic diuretic used for acute oliguric renal failure, to reduce intraocular & intracerebral pressures, to enhance urinary excretion of some toxins &, with other diuretics, to rapidly reduce edema or ascites (caution)
- ▶ Contraindications: Anuria secondary to renal disease, severe dehydration, intracranial bleeding (unless during craniotomy), severe pulmonary congestion, or pulmonary edema
- ▶ Halt treatment if progressive heart failure, pulmonary congestion, or progressive renal failure/damage develop
- ▶ Adverse Effects: Fluid & electrolyte imbalances, GI (nausea, vomiting), cardiovascular (pulmonary edema, CHF, tachycardia), & CNS effects (dizziness, headache, etc.)
- ▶ Adequate urine output, fluid, & electrolyte monitoring & treatment mandatory
- ▶ Be certain crystals are dissolved in solution before administering

Uses/Indications

Mannitol is used to promote diuresis in acute oliguric renal failure, reduce intraocular and intracerebral pressures, enhance urinary excretion of some toxins, (e.g., aspirin, some barbiturates, bromides, ethylene glycol) and, in conjunction with other diuretics, to rapidly reduce edema or ascites when appropriate (see Contraindications-Precautions below). In humans, it is also used as an irrigating solution during transurethral prostatic resections.

Pharmacology/Actions

After intravenous administration, mannitol is freely filtered at the glomerulus and poorly reabsorbed in the tubule. The increased osmotic pressure prevents water from being reabsorbed at the tubule. To be effective, there must be sufficient renal blood flow and filtration for mannitol to reach the tubules. Although water is proportionately excreted at a higher rate, sodium, other electrolytes, uric acid, and urea excretions are also enhanced.

Mannitol may have a nephro-protective effect by preventing the concentration of nephrotoxins from accumulating in the tubular fluid. Additionally, it may minimize renal tubular swelling via its osmotic properties, increase renal blood flow and glomerular filtration by causing renal arteriole dilatation, decreased vascular resistance, and decreased blood viscosity.

Mannitol does not appreciably enter the eye or the CNS, but can decrease intraocular and CSF pressure through its osmotic effects. Rebound increases in CSF pressures may occur after the drug is discontinued.

Pharmacokinetics

Although long believed to be unabsorbed from the GI, up to 17% of an oral dose is excreted unchanged in the urine after oral dosing in humans. After intravenous dosing, mannitol is distributed to the extracellular compartment and does not penetrate the eye. Unless the patient has received very high doses, is acidotic, or there is loss of integrity of the blood-brain barrier, it does not cross into the CNS.

Only 7–10% of mannitol is metabolized, the remainder is excreted unchanged in the urine. The elimination half-life of mannitol is approximately 100 minutes in adult humans. Half-lives in cattle and sheep are reported to be between 40–60 minutes.

Contraindications/Precautions/Warnings

Mannitol is contraindicated in patients with anuria secondary to renal disease, severe dehydration, intracranial bleeding (unless during craniotomy), severe pulmonary congestion or pulmonary edema.

When using for increased CSF pressure, an intact capillary membrane is required for efficacy. If this membrane is disrupted, mannitol can leak into the brain interstitium and increase cerebral edema.

Mannitol therapy should be stopped if progressive heart failure, pulmonary congestion, progressive renal failure or damage (including increasing oliguria and azotemia) develops after mannitol therapy is instituted.

Mannitol is relatively contraindicated for treating secondary glaucomas, as it may cross the damaged “blood-aqueous barrier” and increase intraocular pressure (IOP).

Do not administer more than a test dose of mannitol until determining whether the patient has some renal function and urine output. Adequate fluid replacement must be administered to dehydrated animals before mannitol therapy is begun. Do not give mannitol with whole blood products, unless at least 20 mEq/L of sodium chloride is added to the solution or pseudo-agglutination may result.

Be certain any crystals in solution are redissolved before administering; an in-line IV filter is also recommended.

Adverse Effects

Fluid and electrolyte imbalances are the most severe adverse effects generally encountered during mannitol therapy. Adequate monitoring and support are imperative.

When used for oliguric renal failure, the potential exists for volume overload should oliguria persist.

Other adverse effects that may be encountered include GI (nausea, vomiting), cardiovascular (pulmonary edema, CHF, tachycardia), and CNS effects (dizziness, headache, etc.).

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether this drug is excreted in milk, but it is unlikely that it would pose significant risk to nursing offspring.

Overdosage/Acute Toxicity

Inadvertent overdosage can cause excessive excretion of sodium, potassium, and chloride. If urine output is inadequate, water intoxication or pulmonary edema may occur. Treat by halting mannitol administration and monitoring and correcting electrolyte and fluid imbalances. Hemodialysis is effective in clearing mannitol.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mannitol and may be of significance in veterinary patients:

- **LITHIUM:** Mannitol can increase the renal elimination of lithium
- **SOTALOL:** Mannitol's effects on potassium and magnesium may increase the risk for QT prolongation

Laboratory Considerations

- Mannitol can interfere with **blood inorganic phosphorus** concentrations and **blood ethylene glycol** determinations.

Doses

■ DOGS & CATS:

For treatment of oliguric renal failure:

- After correcting fluid, electrolyte, acid/base balance and determining that the patient is not anuric: Mannitol (20–25% solution) 0.25–0.5 gm/kg IV over 5–10 minutes. If diuresis occurs, may repeat q4–6 hours or administered as a constant infusion (8–10% solution) for first 12–24 hours of therapy. (Polzin 2005a)
- After rehydration, but not fluid overloaded give mannitol at 0.25–0.5 gm/kg IV slowly over 5–10 minutes; repeat dose at 30–40 minute intervals up to 1.5 gm/kg total. Author prefers using furosemide for ARF. (Bersenas 2007)
- In fluid replete animals: 0.5 gram/kg IV over 20–30 minutes; if significant diuresis is accomplished within 30 minutes, may administer as a CRI of 60–120 mg/kg/hr IV or as intermittent boluses repeated every 4–6 hours. Mannitol is contraindicated in patients who are still dehydrated, hypervolemic, or anuric. (Waddell 2007a)
- After rehydration, give mannitol 0.5 gm/kg IV slowly; repeat dose at 15-minute intervals up to 1.5 gm/kg total. Urine production should begin within 15 minutes; monitor carefully for dehydration and give fluids as necessary to maintain balance. (Breitschwerdt 1988)

For adjunctive treatment of acute glaucoma:

- Drug of first choice in the acute patient; 0.5–1 g/kg IV given over 15–20 minutes; withhold water for 3–4 hours. IOP reduction begins in 20–30 minutes and has a 4–6 hour duration of effect. Efficacy reduced in patients with anterior uveitis. (Wilkie 2002)
- If latanaprost (*Xalatan*®) has not affected pupil size and started to reduce IOP after one hour, give mannitol (20%) at 1–2 g/kg IV over a period of 20 minutes and withhold water for 1–2 hours. Peak effect is about 90 minutes after administration. (Millichamp 2006)

For adjunctive treatment of increased CSF pressure/cerebral edema:

- 0.5–1.5 g/kg IV over 10–20 minutes. Maximum effect occurs 10–20 minutes after administration and the effects last for 2–5 hours. May repeat every 6–8 hours based on clinical response and intracranial pressure monitoring. Do not use if patient hypovolemic. Monitor serum osmolality and electrolytes. (McDonnell 2004)
- 0.25–1 gram/kg IV q4–6h as needed (Barton 2002b)
- Secondary to trauma: 100–500 mg/kg slow IV, if a positive effect is seen, may repeat every 2 hours for 3 doses. Crystalloid infusion may need to be adjusted to prevent dehydration or hypovolemia. Furosemide at 0.75 mg/kg may be administered prior to mannitol to reduce CSF formation. (Rudloff 2006a)
- Secondary to trauma: 0.5–1 gram/kg IV followed 20 minutes later by furosemide (1 mg/kg IV). Potential risk for worsening intracranial hemorrhage, but patients that are dying before your eyes can benefit from this aggressive therapy. (Mazzaferro 2007)

To measure glomerular filtration rate in dogs:

- 1.1–2.2 grams/kg IV slowly over 15–30 minutes (McConnell and Hughey 1987)

■ CATTLE, SWINE, SHEEP, GOATS:

For adjunctive treatment of cerebral edema:

- 1–3 gm/kg IV (usually with steroids and/or DMSO) (Dill 1986)

As a diuretic for oliguric renal failure:

- 1–2 gm/kg (5–10mL of 20% solution) IV after rehydration; monitor urine flow and fluid balance (Osweiler 1986)

■ HORSES:

- 0.25–2 gm/kg as a 20% solution by slow IV infusion (Schultz 1986)

Monitoring

- Serum electrolytes, osmolality
- BUN, serum creatinine
- Urine output
- Central venous pressure, if possible
- Lung auscultation

Client Information

- Mannitol should be administered by professional staff in a setting where adequate monitoring can occur.

Chemistry/Synonyms

An osmotic diuretic, mannitol occurs as an odorless, sweet-tasting, white, crystalline powder with a melting range of 165°–168° and a pK_a of 3.4. One gram is soluble in about 5.5 mL of water (at 25°C); it is very slightly soluble in alcohol. The commercially available injectable products have approximate pH's of 4.5–7.

Mannitol may also be known as: cordycepic acid, E421, manita, manitol, manna sugar, mannite, mannitolium, Eufusol M 20, *Am-Vet*® *Mannitol Injection* 20%, *Isotol*®, *Manicol*®, *Manniject*®, *Maniton*®, *Mannistol*®, *Mannit-Losung*®, *Mannite*®, *Mede-Prep*®, *Osmofundin* 15% N®, *Osmofundin* 20%, *Osmofundina*®, *Osmofundina*® *Concentrada*, *Osmorol*®, *Osmosteril*® 20%, *Resectisol*® and *Thomaemannit*®.

Storage/Stability/Compatibility

Mannitol solutions are recommended to be stored at room temperature; avoid freezing.

Crystallization may occur at low temperatures in concentrations greater than 15%. Resolubilization of the crystals can be accomplished by heating the bottle in hot (up to 80°C) water. Cool to body temperature before administering. An in-line IV filter is recommended when administering concentrated mannitol solutions. Alternatively, heated storage chambers (35°–50°C) have been suggested to assure that soluble product is available at all times. Microwaving glass ampules/vials has been suggested, but explosions have been documented and this procedure cannot be recommended. Supersaturated solutions of mannitol in PVC bags may show a white flocculent precipitate that will tend to reoccur even after heating.

Drugs reported to be physically **compatible** with mannitol include: amikacin sulfate, bretylium tosylate, cefamandole naftate, cefoxitin sodium, cimetidine HCl, dopamine HCl, gentamicin sulfate, metoclopramide HCl, netilmicin sulfate, tobramycin sulfate, and verapamil HCl.

Mannitol should not be added to whole blood products to be used for transfusion. Sodium or potassium chloride can cause mannitol to precipitate out of solution when mannitol concentrations are 20% or greater. Mannitol may be physically **incompatible** when mixed with strongly acidic or alkaline solutions.

Mannitol is reportedly stable when mixed with cisplatin for a short period of time, but advanced premixing of the drugs should be avoided because a complex may form between them.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Mannitol for injection 20%: 20 g/100 mL in 100 mL single-dose vials. *Am-Vet® Mannitol Injection 20% (IVX)*; generic (Phoenix Pharm, Neogen); (Rx). Labeled for use in canine species.

Mannitol for Injection 18%: 180 mg/mL in 100 mL vials; *Manniject®* (Butler); generic (Vedco); (Rx). Labeled for use in dogs

HUMAN-LABELED PRODUCTS:

Mannitol for Injection

Mannitol Injection: 5% (50 mg/mL; 275 mOsm/l) in 1000 mL;

10% (100 mg/mL; 550 mOsm/l) in 500 mL and 1000 mL;

15% (150 mg/mL; 825 mOsm/l) in 150 mL & 500 mL;

20% (200 mg/mL; 1100 mOsm/l) in 250 mL and 500 mL;

25% (250 mg/mL; 1375 mOsm/l) in 50 mL vials and syringes (12.5 grams/vial); generic; (Rx)

Mannitol Solution: Genitourinary Irrigants: 5 g/100 mL in distilled water (275 mOsm/L) in 2000 mL; *Resectisol®* (Kendall McGaw); (Rx)

MARBOFLOXACIN

(mar-boe-flox-a-sin) Zeniquin®

FLUOROQUINOLONE ANTIBIOTIC

Prescriber Highlights

- ▶ Veterinary oral fluoroquinolone antibiotic effective against a variety of pathogens
- ▶ Not effective against anaerobes
- ▶ Contraindications: Hypersensitivity to fluoroquinolones; Relatively contraindicated for young, growing animals due to cartilage abnormalities
- ▶ Caution: Hepatic or renal insufficiency, seizure patients, or dehydration
- ▶ Adverse Effects: GI distress; does not appear to cause ocular toxicity in cats
- ▶ Drug interactions

Uses/Indications

Marboploxacin is labeled for the treatment of susceptible bacterial infections in dogs and cats.

Pharmacology/Actions

Marboploxacin is a bactericidal agent. The bactericidal activity of marboploxacin is concentration dependent, with susceptible bacteria cell death occurring within 20–30 minutes of exposure. Like other fluoroquinolones, marboploxacin has demonstrated a significant post-antibiotic effect for both gram - and + bacteria and is active in both stationary and growth phases of bacterial replication.

Its mechanism of action is not thoroughly understood, but it is believed to act by inhibiting bacterial DNA-gyrase (a type-II topoisomerase), preventing DNA supercoiling and DNA synthesis.

Marboploxacin has a similar spectrum of activity as the other veterinary commercially available agents. These agents have good activity against many gram-negative bacilli and cocci, including most species and strains of *Pseudomonas aeruginosa*, *Klebsiella* spp., *E. coli*, *Enterobacter*, *Campylobacter*, *Shigella*, *Salmonella*, *Aeromonas*, *Haemophilus*, *Proteus*, *Yersinia*, *Serratia*, and *Vibrio* species. Other

organisms that are generally susceptible include *Brucella* spp., *Chlamydia trachomatis*, Staphylococci (including penicillinase-producing and methicillin-resistant strains), Mycoplasma, and *Mycobacterium* spp. (not the etiologic agent for Johne's Disease).

The fluoroquinolones have variable activity against most streptococci and are not usually recommended to use for these infections. These drugs have weak activity against most anaerobes and are ineffective in treating anaerobic infections.

Resistance does occur by mutation, particularly with *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, *Acinetobacter*, and Enterococci, but plasmid-mediated resistance is thought to occur only rarely.

Pharmacokinetics

In dogs, marboploxacin is characterized as being rapidly absorbed after oral administration with a bioavailability of 94%. Peak plasma levels occur in about 1.5 hours. Protein binding is low and the apparent volume of distribution is 1.2–1.9 L/kg. Elimination half-life averages 9–12 hours. The drug is eliminated unchanged in the urine (40%) and bile/feces. Only about 15% of a dose is metabolized in the liver.

In cats, absorption after oral dosing is nearly complete and peak serum levels occur about 1–2 hours post-dose. Terminal elimination half-life is about 13 hours.

Renal impairment does not significantly alter dosing requirements.

Contraindications/Precautions/Warnings

Like other quinolones, marboploxacin is labeled as contraindicated in small and medium breed dogs up to 8 months of age, large breeds to 12 months old, and giant breeds to 18 months old. It is also labeled as contraindicated in cats under 12 months of age. Quinolones are also contraindicated in patients hypersensitive to them.

Marboploxacin can (rarely) cause CNS stimulation and should be used with caution in patients with seizure disorders.

The FDA has prohibited the use of this drug in food-producing animals.

Adverse Effects

With the exception of potential cartilage abnormalities in young animals (see Contraindications above), the adverse effect profile of marboploxacin is usually limited to GI distress (vomiting, anorexia, soft stools, diarrhea) and decreased activity.

Other fluoroquinolones have, in rare incidences, caused elevated hepatic enzymes, ataxia, seizures, depression, lethargy, and nervousness in dogs. Hypersensitivity reactions or crystalluria could potentially occur.

It is not known if marboploxacin can also cause the ocular toxicity that has been reported with high dose enrofloxacin in cats. While unlikely, FDA's Adverse Drug Reaction database has received 14 reports (as of July 3, 2007) of blindness associated with marboploxacin. Causal effect cannot be proven, but use higher dosages carefully.

Reproductive/Nursing Safety

Safety of marboploxacin during pregnancy has not been established.

Overdosage/Acute Toxicity

It is unlikely an acute overdose of marboploxacin would result in signs more serious than either anorexia or vomiting, but the adverse effects noted above could occur. Dogs receiving 55 mg/kg per day for 12 days developed anorexia, vomiting, dehydration, tremors, red skin, facial swelling, lethargy, and weight loss.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving marbofloxacin or related fluoroquinolones and may be of significance in veterinary patients:

- **ANTACIDS/DAIRY PRODUCTS:** Containing cations (Mg^{++} , Al^{+++} , Ca^{++}) may bind to marbofloxacin and prevent its absorption; separate doses of these products by at least 2 hours
- **ANTIBIOTICS, OTHER (aminoglycosides, 3rd-generation cephalosporins, penicillins—extended-spectrum):** Synergism may occur, but is not predictable, against some bacteria (particularly *Pseudomonas aeruginosa*) with these compounds. Although marbofloxacin has minimal activity against anaerobes, *in vitro* synergy has been reported when used with **clindamycin** against strains of *Peptostreptococcus*, *Lactobacillus* and *Bacteroides fragilis*.
- **CYCLOSPORINE:** Fluoroquinolones may exacerbate the nephrotoxicity and reduce the metabolism of cyclosporine (used systemically)
- **FLUNIXIN:** Has been shown in dogs to increase the AUC and elimination half-life of enrofloxacin and enrofloxacin increases the AUC and elimination half-life of flunixin; it is unknown if marbofloxacin also causes this effect or if other NSAIDs interact with marbofloxacin in dogs
- **GLYBURIDE:** Severe hypoglycemia possible
- **IRON, ZINC (oral):** Decreased marbofloxacin absorption; separate doses by at least two hours
- **METHOTREXATE:** Increased MTX levels possible with resultant toxicity
- **NITROFURANTOIN:** May antagonize the antimicrobial activity of the fluoroquinolones and their concomitant use is not recommended
- **PHENYTOIN:** Marbofloxacin may alter phenytoin levels
- **PROBENECID:** Blocks tubular secretion of ciprofloxacin and may also increase the blood level and half-life of marbofloxacin
- **SUCRALFATE:** May inhibit absorption of marbofloxacin; separate doses of these drugs by at least 2 hours
- **THEOPHYLLINE:** Marbofloxacin may increase theophylline blood levels
- **WARFARIN:** Potential for increased warfarin effects

Laboratory Considerations

- In some human patients, the fluoroquinolones have caused increases in liver enzymes, BUN, and creatinine and decreases in hematocrit. The clinical relevance of these mild changes is not known at this time.

Doses

■ DOGS & CATS:

- a) For susceptible infections (urinary tract, skin and soft tissue): 2.75–5.5 mg/kg PO once daily. Give for 2–3 days beyond cessation of clinical signs (skin/soft tissue infections); and for at least 10 days (urinary tract). If no improvement noted after 5 days, reevaluate diagnosis. Maximum duration of treatment is 30 days. (Package insert; *Zeniquin*®—Pfizer)

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- Give as the veterinarian prescribes; do not stop treating just because the animal appears well.

Chemistry/Synonyms

A synthetic fluoroquinolone antibiotic, marbofloxacin is soluble in water, but solubility decreases as pH increases.

Marbofloxacin may also be known as Ro 9-1168, *Marbocyl*®, or *Zeniquin*®.

Storage/Stability

Marbofloxacin tablets should be stored below 30°C.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Marbofloxacin Oral Tablets: 25 mg, 50 mg, 100 mg, 200 mg; *Zeniquin*® (Pfizer); (Rx). Approved for use in dogs and cats. Must not be used in food animals.

HUMAN-LABELED PRODUCTS: None

MAROPITANT CITRATE

(mar-oh-pit-ent) Cerenia®

NEUROKININ (NK_1) RECEPTOR ANTAGONIST
ANTIEMETIC

Prescriber Highlights

- Veterinary approved antiemetic for use in dogs 16 weeks of age & older; also used extra-label in cats
- Acts at the emetic center; therefore effective for emesis mediated via either peripheral or central mechanisms
- Subcutaneous injection is approved for the prevention & treatment of acute vomiting;
- Oral form is approved for the prevention of acute vomiting & the prevention of vomiting due to motion sickness; different oral dosages for each indication
- Oral dose is higher than subcutaneous dose due to decreased bioavailability of the oral tablet

Monograph by Dinah Jordan, PharmD, DICVP

Uses/Indications

Maropitant citrate injectable solution is indicated for the prevention and treatment of acute vomiting in dogs; maropitant citrate tablets are indicated for the prevention of acute vomiting and the prevention of vomiting due to motion sickness in dogs. Both are also used extra-label in cats.

Pharmacology/Actions

Maropitant is a neurokinin-1 (NK_1) receptor antagonist, which acts in the central nervous system by inhibiting Substance P, the key neurotransmitter involved in vomiting. Maropitant suppresses both peripheral & centrally mediated emesis.

Pharmacokinetics

In dogs, maropitant is rapidly absorbed after oral (PO) & subcutaneous (SC) administration. Peak plasma concentrations (T_{max}) occur in less than 1 hour following 1 mg/kg subcutaneous administration and less than 2 hours after oral administration of 2 or 8 mg/kg. After oral administration bioavailability is 24% (2 mg/kg) and 37% (8 mg/kg), suggesting first pass metabolism which becomes saturated at the higher dose. Feeding status does not affect bioavailability.

Maropitant follows non-linear pharmacokinetics (PK) at oral therapeutic doses but approximately linear PK at higher doses (20–50 mg/kg). Bioavailability is 91% following subcutaneous administration of 1 mg/kg. An accumulation ratio of 1.5 occurs after once daily use of maropitant for 5 consecutive days at 1 mg/kg SC or 2 mg/kg PO. Accumulation ratio is 2.18 after 2 consecutive days at 8 mg/kg PO daily.

Hepatic metabolism of maropitant involves two cytochrome P450 enzymes: CYP2D15 (low capacity, high affinity) and CYP3A12 (high capacity, low affinity). The non-linear kinetics at oral doses of 2–16 mg/kg may be due to saturation of the low capacity enzyme and increased involvement of CYP3A12 at higher doses. Twenty-one metabolites have been identified with the major (pharmacologically active) metabolite being CJ-18,518, a product of hydroxylation. Plasma protein binding of maropitant is high (99.5%). Half-life is 8.84 hours (range: 6.07–17.7 hrs) for 1 mg/kg SC; 4.03 hours (range: 2.58–7.09 hrs) for 2 mg/kg. Maropitant is eliminated primarily by the liver. Urinary recovery of maropitant and its major metabolite is minimal (<1%). Large inter-patient pharmacokinetic variations have been observed.

No information on the pharmacokinetics of maropitant in cats was located.

Contraindications/Precautions/Warnings

Use with caution in dogs with hepatic dysfunction.

Use with caution with other medications that are highly protein bound, although clinical significance has not been determined.

Adverse Effects

Maropitant is well tolerated in dogs. Pre-travel vomiting and hypersalivation are the two most common side effects seen after administration of the tablets at the higher dosage required for prevention of motion sickness. Swelling or pain at the injection site has been reported following SC administration of the drug. Diarrhea (4–8%) & anorexia (1.5–5.2%) were the most common side effects noted during U.S. field studies.

Reproductive/Nursing Safety

The safe use of maropitant has not been evaluated in dogs used for breeding, pregnant or lactating bitches. Maropitant should only be used in pregnant or lactating bitches following a benefit/risk assessment by the veterinarian.

Overdosage/Acute Toxicity

Single dose toxicity was studied in mice and rats after oral and intravenous administration. No adverse events were reported after oral administration of up to 30 mg/kg (mice) and 100 mg/kg (rats) and after IV administration of 6.5 mg/kg (mice) and 2.5 mg/kg (rats). The clinical signs of overdosage in mice and rats were similar and independent from the route of administration and included decreased activity, irregular or labored respiration, ataxia and tremors. Salivation, nasal discharge and “raspy” breathing were also noted in rats after oral dosing, while the excretion of reddish urine was observed in some mice and rats following intravenous administration.

In dogs, tolerance has been confirmed in doses of up to 3 times the recommended oral dose of 8 mg/kg, for 3 times longer than the proposed maximum duration of treatment. A GLP compliant study revealed no adverse events in dogs after repeated oral doses delivered by oral gavage (5 mg/kg PO q 24h x 93 days). In the same study at 20 mg/kg/day, effects included emesis in two females on day 1, body weights losses of 8–15% when compared to those at start of study, ECG changes (slight increases in P-R interval, P wave duration and QRS amplitude were noted over the course of treatment), slightly lower serum albumin and slightly higher adrenal weights (females) at 20 mg/kg/day in both sexes.

Oral toxicokinetic studies with the primary metabolite were conducted in mice, rats, rabbits and dogs, indicating that the metabolite was well tolerated.

Drug Interactions

At the time of writing, no specific drug interactions have been identified. During field safety and efficacy studies, a number of medications were used concomitantly with maropitant. Many dogs received multiple medications. The most common concomitant medication was metronidazole. Other commonly used concomitant medications included: dextrose/Ringers solution IV, sodium chloride IV, amoxicillin, ampicillin, cefazolin, cephalexin, enrofloxacin, sulfamethoxazole/trimethoprim, famotidine, sucralfate, cimetidine, dexamethasone, ivermectin, ivermectin/pyrantel, pyrantel, lufenuron/milbemycin, milbemycin, moxidectin, vitamin B, and vaccines. There were no problems observed with any of these drugs in conjunction with maropitant.

Laboratory Considerations

No specific concerns noted.

Doses

■ DOGS:

(**Note:** The following dosages have also been used extra-label in cats—Jordan)

Prevention of acute vomiting:

1 mg/kg SC given at least one hour prior to anticipated emetogenic event and q24h thereafter for up to 5 consecutive days.

2 mg/kg PO given at least two hours prior to anticipated emetogenic event and q24h thereafter for up to 5 consecutive days.

Treatment of acute vomiting:

1 mg/kg SC q24h for up to 5 consecutive days.

Note: If a longer duration of therapy is needed, a 48 hour washout period is recommended due to accumulation of the drug.

Prevention of vomiting due to motion sickness:

8 mg/kg (minimum dose) PO given at least two hours prior to travel and q24h for up to 2 consecutive days;

Note: If a longer duration of therapy is needed, a 72 hour washout period is recommended.

(Label Information; *Cerenia*®—Pfizer)

Monitoring

- Clinical efficacy measured by decreased episodes of vomiting
- Adverse effects

Client Information

- Tablets should not be tightly wrapped or embedded in food/snacks as this may delay dissolution of tablets
- Avoid prolonged fasting before administration of tablets
- Feeding a small meal or snack one hour before administration of tablets for motion sickness will minimize the occurrence of pre-trip vomiting following administration of tablets

Chemistry/Synonyms

Classified as a substituted quinuclidine, maropitant's molecular weight is 678.81. The chemical name is (2S,3S)-2-benzhydryl-N-(5-tert-butyl-2-methoxybenzyl) quinuclidin-3-amine citrate.

Maropitant may also be known as CJ-11,972.

Storage/Stability

Maropitant injectable solution contains a preservative and is designed for multi-dose use. The vial should be stored at controlled room temperature 20–25°C (68–77°F) with excursions permitted between 15–30°C (59–86°F). The product label states the drug should be used within 28 days of first vial puncture in accordance with FDA requirements. Although the product may be chemically stable beyond this time, multiple punctures may lead to contamination of the product; therefore, extended use beyond the labeled discard date is discouraged.

Maropitant tablets are packaged in foil to protect them from moisture uptake, which was observed in less-protective packaging. A European stability study indicated that tablets removed from the blister pack and halved showed no loss of potency during the 48 hour testing period.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Maropitant Citrate Injectable Solution: 10 mg/mL in 20 mL multi-dose vials; *Cerenia*® (Pfizer); (Rx). Labeled for use in dogs.

Maropitant Citrate Oral Tablets: 16, 24, 60, and 160 mg in blister packs (4 tablets per pack; carton of 10); Tablets are peach-colored and scored with the tablet strength and MPT imprinted on one side and the Pfizer logo imprinted on the other side; *Cerenia*® (Pfizer); (Rx). Labeled for use in dogs.

HUMAN-LABELED PRODUCTS: None

MECHLORETHAMINE HCL

(me-klor-eth-a-meen) Mustargen®

ANTINEOPLASTIC**Prescriber Highlights**

- ▶ Antineoplastic for lymphoreticular neoplasms or pleural & peritoneal effusions (intracavitary)
- ▶ Contraindications (relative; risk vs. benefit): Anemia, bone marrow depression, tumor cell infiltration into bone marrow, current infection, sensitivity to mechlorethamine, or patients who have received previous chemotherapy or radiotherapy
- ▶ Adverse Effects: Bone marrow depression, GI effects (vomiting, nausea), ototoxicity (high dosages or regional perfusions); Potentially: alopecia, hyperuricemia, hepatotoxicity, peripheral neuropathy, & GI ulcers
- ▶ Teratogen
- ▶ Avoid extravasation

Uses/Indications

In small animals, mechlorethamine may be useful for the adjunctive treatment of lymphoreticular neoplasms or, with intracavitary administration, for treating pleural and peritoneal effusions. A change in owners of the pharmaceutical product has reportedly resulted in very large price increases for this medication and some veterinary oncologists are substituting dactinomycin for the mechlorethamine in MOPP rescue protocols.

Pharmacology/Actions

Mechlorethamine is an alkylating agent, thereby interfering with DNA replication, RNA transcription, and protein synthesis. It is cell cycle-phase nonspecific.

With intracavitary administration, mechlorethamine causes sclerosing and an inflammatory response on serous membranes, thereby causing adherence of serosal surfaces.

Pharmacokinetics

Because mechlorethamine is so irritating to tissues it must be given IV for systemic use. It is incompletely absorbed after intracavitary administration. After injection, mechlorethamine is rapidly (within minutes) inactivated.

Contraindications/Precautions/Warnings

Mechlorethamine is contraindicated in patients with a known infection or have had a prior anaphylactic reaction to the drug.

Mechlorethamine should be used only when its potential benefits outweigh its risks with the following conditions: anemia, bone marrow depression, tumor cell infiltration into bone marrow, sensitivity to mechlorethamine, or patients who have received previous chemotherapy or radiotherapy.

Adverse Effects

Bone marrow depression (leukopenia, thrombocytopenia) and GI effects (vomiting, nausea) are quite common and can be serious enough to halt therapy. Ototoxicity may occur with either high dosages or regional perfusions. Other potential effects include alopecia, hyperuricemia, hepatotoxicity, peripheral neuropathy, and GI ulcers.

Because severe tissue sloughing may occur, avoid extravasation.

Reproductive/Nursing Safety

Mechlorethamine is a teratogen in lab animals. Use only during pregnancy when the benefits to the mother outweigh the risks to the offspring. Mechlorethamine can suppress gonadal function. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

While it is not known whether mechlorethamine enters maternal milk, nursing puppies or kittens should receive milk replacer when the dam is receiving mechlorethamine.

Overdosage/Acute Toxicity

Because of the toxic potential of this agent, overdoses must be avoided. Determine dosages carefully.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mechlorethamine and may be of significance in veterinary patients:

- **IMMUNOSUPPRESSANT DRUGS** (e.g., azathioprine, cyclophosphamide, corticosteroids): Use with other immunosuppressant drugs may increase the risk of infection.
- **MYELOSUPPRESSIVE DRUGS** (e.g., chloramphenicol, flucytosine, amphotericin B, or colchicine): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs. Bone marrow depression may be additive.
- **VACCINES, LIVE:** Live virus vaccines should be used with caution, if at all, during therapy.

Laboratory Considerations

- Mechlorethamine may raise **serum uric acid** levels. Drugs such as allopurinol may be required to control hyperuricemia.

Doses

For more information on using mechlorethamine as part of chemotherapy protocols, refer to the protocols found in the appendix or other dosages/protocols found in numerous references, including: *Withrow and MacEwen's Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

■ DOGS:

For the adjunctive treatment of lymphoreticular neoplasms or with intracavitary administration for treating pleural and peritoneal effusions:

- a) 5 mg/m² IV or intracavitary; repeat as needed (Jacobs, Lumsden et al. 1992)

For MOPP lymphoma rescue:

- a) Mechlorethamine: 3 mg/m² IV days 1 and 7; Vincristine: 0.7 mg/m² IV days 1 and 7; Procarbazine: 50 mg/m² PO daily days 1–14; Prednisone: 30 mg/m² PO daily day 1–14. No treatment given days 15–28 and then protocol is repeated at 4 weeks. Protocol may be severely myelosuppressive. (Meleo 2003)

■ CATS:

For MOPP lymphoma rescue:

- a) Mechlorethamine: 3 mg/m² IV days 1 and 7; Vincristine: 0.5 mg/m² IV days 1 and 7; Procarbazine: 50 mg/m² PO daily days 1–14; Prednisone: 30 mg/m² PO daily day 1–14. No treatment given days 15–28 and then protocol is repeated at 4 weeks. Cats may require 5-week cycle due to myelosuppression. (Meleo 2003)
- b) Mechlorethamine: 3 mg/m² IV days 0 and 7; Vincristine: 0.025 mg/kg IV days 0 and 7; Procarbazine: 10 mg (total dose) PO daily days 0–14; Prednisone: 5 mg (total dose) PO twice daily continuously. May also be considered for inducing first remission in cats. Anorexia may be reduced if procarbazine is given every other day or given with metoclopramide. (Frimberger 2002)

Monitoring

- CBC with platelets at least every 1–2 weeks until stable; then every 3 months
- Liver function tests; initially before starting treatment and then every 3–4 months
- Injection site for signs of extravasation

Chemistry/Synonyms

A bifunctional alkylating agent, mechlorethamine occurs as a hygroscopic, white, crystalline powder that is very soluble in water. After reconstitution with sterile water or sterile saline, the resultant solution is clear and has a pH of 3–5.

Mechlorethamine may also be known as: nitrogen mustard, mustine, HN₂, chlormethine hydrochloride, chlorethazine hydrochloride, HN₂ (mustine [chlormethine]), mechlorethamine hydrochloride, mustine hydrochloride, nitrogen mustard (mustine [chlormethine]), NSC-762, WR-147650, *Caryolysine*®, *Mustargen*® and *Onco-Cloramin*®.

Storage/Stability

Store the powder for injection at room temperature. Mechlorethamine is highly unstable in neutral or alkaline aqueous solutions and rapidly degrades. While more stable in an acidic environment, the drug should be administered immediately after preparation.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Mechlorethamine Powder for Injection: 10 mg; *Mustargen*® (Ovation); (Rx)

MECLIZINE HCL

(mek-li-zeen) Antivert®

ANTI-HISTAMINE, ANTI-EMETIC

Prescriber Highlights

- Antihistamine with sedative & antiemetic effects, used primarily for motion sickness
- Contraindications: Known hypersensitivity
- Caution: Prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyloduodenal obstruction
- Adverse Effects: Sedation; less frequently anticholinergic effects may be noted (dry mucous membranes, eyes, tachycardia, etc.); contradictory CNS stimulation possible

Uses/Indications

Meclizine is principally used in small animals as an antiemetic and for the treatment and prevention of motion sickness.

Pharmacology/Actions

Meclizine is a piperazine antihistamine and, beside its antihistamine activity, it also possesses antiemetic, CNS depressant, antispasmodic, and local anesthetic effects. The exact mechanisms of action for its antiemetic and anti-motion-sickness effects are not completely understood, but it is thought they are as a result of the drug's central anticholinergic and CNS depressant activity. The antiemetic effect is probably mediated through the chemoreceptor trigger zone (CTZ).

Pharmacokinetics

Very little information is available. Meclizine is metabolized in the liver and has a serum half-life of about 6 hours.

Contraindications/Precautions/Warnings

Meclizine is contraindicated in patients hypersensitive to it. It should be used with caution in patients with prostatic hypertrophy, bladder neck obstruction, severe cardiac failure, angle-closure glaucoma, or pyloduodenal obstruction.

Adverse Effects

The usual adverse effect noted with meclizine is sedation; less frequently anticholinergic effects may be noted (dry mucous membranes, eyes, tachycardia, etc.). Contradictory CNS stimulation has also been reported. Cats may develop inappetence while receiving this medication.

Reproductive/Nursing Safety

Meclizine is considered teratogenic at high dosages in laboratory animals and cleft palates have been noted in rats at 25–50 times higher than labeled dosages. However, in humans, it has been suggested that meclizine possesses the lowest risk for teratogenicity for antiemetic drugs and that it is the drug of first choice to treat nausea/vomiting associated with pregnancy. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is unknown if meclizine enters milk; its anticholinergic activity may, potentially, inhibit lactation.

Overdosage/Acute Toxicity

Moderate overdosage may result in drowsiness alternating with hyperexcitability. Massive overdosages may result in profound CNS depression, hallucinations, seizures and other anticholinergic effects (tachycardia, urinary retention, etc.). Treatment is considered symptomatic and supportive. Consider gut emptying when patients present soon after ingestion. Avoid respiratory depressant medications.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving meclizine and may be of significance in veterinary patients:

- **CNS DEPRESSANTS:** Use with other CNS depressants may cause additive sedation
- **ANTICHOLINERGIC DRUGS:** Other anticholinergic drugs may cause additive anticholinergic effects

Laboratory Considerations

- Because these drugs are antihistamines, they may affect the results of **skin tests** using allergen extracts. Do not use within 3–7 days before testing.

Doses

■ DOGS:

- a) For supportive treatment of peripheral vestibular disease: 25 mg per dog PO once daily. Treatment is usually unnecessary after 72–96 hours. (Hoskins 2005c)
- b) 25 mg per dog PO once daily. For motion sickness, give one hour before traveling (Papich 1992)
- c) As an antihistamine: 25 mg PO once daily (Bevier 1990)
- d) As anti-emetic: 4 mg/kg PO once a day (Dowling 2003a)
- e) For palliative treatment of vertigo: 25 mg per dog PO once daily. (Schubert 2007)

■ CATS:

- a) 12.5 mg per cat PO once daily (Pearce 2006a)
- b) 6.25 mg/5 kg of body weight PO (Day 1993)
- c) As anti-emetic: 4 mg/kg PO once a day (Dowling 2003a)
- d) For palliative treatment of vertigo: 12.5 mg per cat PO once daily. (Schubert 2007)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: For Rolling, torticollis, motion sickness: 2–12 mg/kg PO once daily (Ivey and Morrissey 2000)
- b) Rabbits: For adjunctive treatment of torticollis, head tilt (“wry neck”): 12.5 mg (total dose) PO q12–24h. (Johnson 2006e)

Monitoring

- Efficacy
- Adverse effects

Client Information

- When using for motion sickness prevention, instruct client to give medication 30–60 minutes before travel.

Chemistry/Synonyms

Meclizine HCl is a piperazine derivative antiemetic antihistamine. Meclizine may also be known as: meclozine hydrochloride, meclizine hydrochloride; meclizinium chloride; meclozini hydrochloridum; parachloramine hydrochloride, *Agyrax*®, *Ancolan*®, *Antivert*®, *Antrizine*®, *Bonamine*®, *Bonine*®, *Calmonal*®, *Chiclida*®, *D-Vert 30*®, *Dizmiss*®, *Dramamine II*®, *Dramine*®, *Duremesan*®, *Emetostop*®, *Marevit*®, *Meni-D*®, *Navicalm*®, *Neo-Istafene*®, *Nico-Vert*®, *Peremesin*®, *Peremesin N*®, *Peremesine*®, *Postadoxin N*®, *Postafen*®, *Postafene*®, *Ru-Vert-M*®, *Sea-Legs*®, *Suprimal*®, *Vergon*®, and *Vertin*®.

Storage/Stability/Compatibility

Meclizine products should be stored at room temperature in well-closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Meclizine HCl Tablets: 12.5 mg, 25 mg (plain and chewable), 50 mg; *Antivert*® (Pfizer); (Rx); *Antrizine*® (Major); (Rx); *Antivert/25*® (Pfizer US); (Rx); *Dramamine® Less Drowsy Formula* (Pfizer); (OTC); *Bonine*® (Pfizer Consumer); (OTC); *Antivert/50*® (Pfizer); (Rx); generic; (Rx and OTC).

MEDETOMIDINE HCL

(mee-de-toe-mi-deen) Domitor®

ALPHA-2 ADRENERGIC AGONIST

Prescriber Highlights

- Alpha₂-adrenergic sedative analgesic used primarily in dogs & cats, but also may be useful in small mammals, exotics, etc.
- Contraindications: Cardiac disease, respiratory disorders, liver or kidney diseases, shock, severe debilitation, or animals stressed due to heat, cold or fatigue. Caution in very old or young animals
- NOT recommended for use during pregnancy
- Adverse Effects: Bradycardia, occasional AV blocks, decreased respiration, hypothermia, urination, vomiting, hyperglycemia, & pain on injection (IM). Rarely: prolonged sedation, paradoxical excitation, hypersensitivity, apnea & death from circulatory failure
- Drug interactions

Uses/Indications

Medetomidine is labeled for use as a sedative and analgesic in dogs over 12 weeks of age to facilitate clinical examinations and procedures, minor surgical procedures not requiring muscle relaxation, and minor dental procedures not requiring intubation. The manufacturer recommends the IV route of administration for dental procedures.

Medetomidine has also been used in cats, primarily in Europe. But there is apparently much less data available to evaluate its use; caution is advised.

Pharmacology/Actions

An alpha adrenergic receptor, medetomidine has an $\alpha_2:\alpha_1$ selectivity factor of 1620, and when compared to xylazine is reportedly 10X more specific for α_2 receptors versus α_1 receptors. The pharmacologic effects of medetomidine include: depression of CNS (sedation, anxiolysis), GI (decreased secretions, varying effects on intestinal muscle tone) and endocrine functions, peripheral and cardiac vasoconstriction, bradycardia, respiratory depression, diuresis, hypothermia, analgesia (somatic and visceral), muscle relaxation (but not enough for intubation), and blanched or cyanotic mucous membranes. Effects on blood pressure are variable, but medetomidine can cause hypertension longer than does xylazine. Medetomidine also induces sedation for a longer period than does xylazine.

Pharmacokinetics

After IV or IM injection, onset of effect is rapid (5 min. for IV; 10–15 min. for IM). After SC injection, responses are unreliable and this method of administration cannot be recommended. The drug is absorbed via the oral mucosa when administered sublingually in dogs, but efficacy at a given dose may be less than IM dosing.

Contraindications/Precautions/Warnings

The label states that medetomidine is contraindicated in dogs having the following conditions: cardiac disease, respiratory disorders, liver or kidney diseases, shock, severe debilitation, or dogs stressed due to heat, cold, or fatigue.

Dogs that are extremely agitated or excited may have a decreased response to medetomidine; the manufacturer suggests allowing these dogs to rest quietly before administration of the drug. Dogs not responding to medetomidine should not be re-dosed. Use in very young or older dogs should be done with caution.

Adverse Effects

The adverse effects reported with medetomidine are essentially extensions of its pharmacologic effects including bradycardia, occasional AV blocks, decreased respiration, hypothermia, urination, vomiting, hyperglycemia, and pain on injection (IM). Rare effects have also been reported, including prolonged sedation, paradoxical excitation, hypersensitivity, apnea, and death from circulatory failure.

Reproductive/Nursing Safety

The drug is not recommended for use in pregnant dogs or those used for breeding purposes because safety data for use during pregnancy is insufficient; therefore, use only when the benefits clearly outweigh the drug's risks.

Overdosage/Acute Toxicity

Single doses of up to 5X (IV) and 10X (IM) were tolerated in dogs, but adverse effects can occur (see above). Death has occurred rarely in dogs (1 in 40,000) receiving 2X doses.

Because of the potential of additional adverse effects occurring (heart block, PVC's, or tachycardia), treatment of medetomidine-induced bradycardia with anticholinergic agents (atropine or gly-

copyrrolate) is usually not recommended. Atipamezole is probably a safer choice to treat any medetomidine-induced effect.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving medetomidine and may be of significance in veterinary patients:

Note: Before attempting combination therapy with medetomidine, it is strongly advised to access references from veterinary anesthesiologists familiar with the use of this product.

- **ATROPINE, GLYCOPYRROLATE:** The use of atropine or glycopyrrolate to prevent or treat medetomidine-caused bradycardia is controversial as tachycardia and hypertension may result. This is more important when using higher doses of medetomidine (>20 mcg/kg) and concomitant use is discouraged.
- **OPIATES:** Enhancement of sedation and analgesia may occur when medetomidine is used concurrently with fentanyl, butorphanol, or meperidine, but adverse effects may be pronounced as well. Reduced dosages and monitoring is advised if contemplating combination therapy.
- **PROPOFOL:** When propofol is used after medetomidine, hypoxemia may occur. Dosage adjustments may be required along with adequate monitoring.
- **YOHIMBINE:** May reverse the effects of medetomidine; but atipamezole is preferred for clinical use to reverse the drug's effects

Laboratory Considerations

- Medetomidine can inhibit ADP-induced platelet aggregation in cats.

Doses

■ DOGS:

For sedation/analgesia:

- a) 750 mcg (0.75 mg)/m² body surface area IV or 1000 mcg (1 mg)/m² body surface area IM. Allow to rest quietly for 15 minutes after injection. Practically, the following dosing table may be used:

IV DOSING WEIGHT IN LBS.	INJECTION VOLUME IN ML	IM DOSING WEIGHT IN LBS.
3–4	0.1	-
5–7	0.15	4–5
8–11	0.2	6–7
12–15	0.25	8–9
16–21	0.3	10–14
22–31	0.4	51–20

(Package Insert; Domitor®—Pfizer)

- b) 10–40 mcg/kg IM; higher doses do not cause greater sedation, but increase the duration of effect (McGrath and Ko 1997)
- c) For use with an IM opioid: 5–10 mcg/kg (Hardie 2000)
- d) 0.001–0.01 mg/kg (1–10 mcg/kg) IV, IM or SC (Carroll 1999)

■ CATS:

For sedation/analgesia:

- a) 40–80 mcg/kg IM; higher doses do not cause greater sedation, but increase the duration of effect (McGrath and Ko 1997)
- b) For use with an IM opioid: 5–10 mcg/kg (Hardie 2000)
- c) 0.001–0.01 mg/kg (1–10 mcg/kg) IV, IM or SC (Carroll 1999)
- d) For large, exotic cat (tigers, etc.) immobilization: Midazolam (0.1 mg/kg) plus medetomidine (0.05–0.07 mg/kg) IM followed by ketamine (4–10 mg/kg) IM, if needed. May antagonize with atipamezole (0.25–0.35 mg/kg) IV, SC. (Curro 2002)

■ SMALL MAMMALS/RODENTS:

For chemical restraint:

- a) Rats: 0.25–0.5 mg/kg IM;
Guinea pig: 0.5 mg/kg IM;
Rabbits: 0.25–0.5 mg/kg IM (Burke 1999)

■ FERRETS:

As a sedative/analgesic:

- a) 15 minutes prior to medetomidine, give atropine (0.05 mg/kg or glycopyrrolate (0.01 mg/kg) then give medetomidine at 60–80 mcg/kg IM or SC. Sedation lasts for up to 3 hours. May be reversed with atipamezole (400 mcg/kg IM);
For injectable anesthesia: Butorphanol 0.1 mg/kg, Ketamine 5 mg/kg, Medetomidine 80 mcg/kg. Combine in one syringe and give IM. May need to supplement with isoflurane (0.5–1.5%) for abdominal surgery. (Finkler 1999)

■ BIRDS:

For sedation/analgesia:

- a) 0.1 mg/kg IM; limited data available on duration of effect, adverse effects, etc. (Clyde and Paul-Murphy 2000)

■ REPTILES:

- a) Medium to small land Tortoises: Medetomidine 100–150 mcg/kg with ketamine 5–10 mg/kg IV or IM;
Freshwater Turtles: Medetomidine 150–300 mcg/kg with ketamine 10–20 mg/kg IV or IM;
Giant Land Tortoises: 200 kg Aldabra tortoise: Medetomidine 40 mcg/kg with ketamine 4 mg/kg IV or IM;
Smaller Aldabra tortoises: Medetomidine 40–80 mcg/kg with ketamine 4–8 mg/kg IV or IM. Wait 30–40 minutes for peak effect.
Iguanas: Medetomidine 100–150 mcg/kg with ketamine 5–10 mg/kg IV or IM;
Reversal of all dosages with atipamezole is 4–5 times the medetomidine dose. (Heard 1999)

Monitoring

- Level of sedation and analgesia; heart rate; body temperature
- Heart rhythm, blood pressure, respiration rate, and pulse oximetry should be considered, particularly in higher risk patients if the drug is to be used

Client Information

- This drug should be administered and monitored by veterinary professionals only
- Clients should be made aware of the potential adverse effects associated with its use, particularly in dogs at risk (older, preexisting conditions)

Chemistry/Synonyms

An alpha₂-adrenergic agonist, medetomidine occurs as a white or almost white crystalline substance. It is soluble in water. While the compound exists as two stereoisomers, only the D-isomer is active.

Medetomidine HCl may also be known as MPV-785 and Domitor®.

Storage/Stability/Compatibility

The commercially available injection should be stored at room temperature (15–30°C) and protected from freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Medetomidine HCl for Injection: 1 mg/mL in 10 mL multidose vials; Domitor® (Pfizer); (Rx). Approved for use in dogs over 12 weeks of age.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS: None

MEDIUM CHAIN TRIGLYCERIDES (MCT OIL)

NUTRITIONAL

Prescriber Highlights

- Lipid used to provide calories & fatty acids to animals with restricted fat intake due to chronic infiltrative disease of small intestine or fat malabsorption syndromes present
- Cautions: Significant hepatic disease (e.g., portacaval shunts, cirrhosis, etc.)
- Adverse Effects: Unpalatability, bloating, flatulence, & diarrhea
- Unpalatable if given alone, mix with food

Uses/Indications

MCT oil is sometimes used to offset the caloric reduction when long-chain triglycerides found in dietary fat are restricted, usually in chronic infiltrative diseases of the small intestine or when there is fat malabsorption of any cause. Because of expense and unpalatability, many clinicians are bypassing MCT oil and having their clients prepare homemade, highly digestible, ultra-low fat diets (e.g., white turkey meat plus rice/potato) or using very low fat prescription diets.

Pharmacology/Actions

Medium chain triglycerides (MCT) are more readily hydrolyzed than conventional food fat. They also require less bile acids for digestion, are not dependent for chylomicron formation or lymphatic transport, and are transported by the portal vein. Medium chain triglycerides are not a source for essential fatty acids.

Pharmacokinetics

No specific information located, see Pharmacology above.

Contraindications/Precautions/Warnings

MCT oil should be used with caution in patients with significant hepatic disease (e.g., portacaval shunts, cirrhosis, etc.). Medium chain triglycerides are rapidly absorbed via the portal vein and if their hepatic clearance is impaired, significantly high systemic blood and CSF levels of medium chain fatty acids can occur. This may precipitate or exacerbate hepatic coma.

Adverse Effects

Adverse effects seen with MCT oil in small animals include unpalatability, bloating, flatulence, and diarrhea. These may be transient and minimized by starting doses at the low end of the spectrum and then gradually increasing the dose. Fat-soluble vitamin supplementation (Vitamins A, D, E, and K) by using a commercial feline or canine vitamin-mineral supplement has been recommended.

Reproductive/Nursing Safety

Although, no reproductive safety data was located, MCT oil would likely not cause problems.

Overdosage/Acute Toxicity

Overdosage would likely exacerbate the GI adverse effects noted above. Treat severe diarrhea supportively if necessary.

Drug Interactions

None listed, but MCT oil could, theoretically, affect absorption of drugs that are dependent on fat for oral absorption (e.g., griseofulvin, fat soluble vitamins, etc.).

Doses

■ DOGS:

To offset the caloric reduction when long-chain triglycerides found in dietary fat are restricted:

- Orally ½–4 teaspoons divided per day with food (Williams 2000)
- Begin with one teaspoonful per meal added to food and slowly increase to a maximal tolerated dose, not to exceed 30 mL per lb of food (Zimmer 1986)
- 1–2 mL/kg per day (Steiner 2003)

Monitoring

- Adverse Effects
- Efficacy (weight, stool consistency)

Client Information

- Because of the unpalatability of the oil, it should be mixed with small quantities of food before offering to the patient.

Chemistry/Synonyms

MCT Oil is a lipid fraction of coconut oil consisting principally of the triglycerides C₈ (approx. 67%) and C₁₀ (approx. 23%) saturated fatty acids. Each 15 mL contains 115 kCal (7.67 kCal/mL).

Medium chain triglycerides may also be known as: triglycerida saturata media, *Alembicol D*®, *Liprocil*®, *Liquigen*®, *MCT*®, *Mytic 810*®, *Structolipid*®, and *Teceeme*®.

Storage/Stability

Unless otherwise noted by the manufacturer, store at room temperature in glass bottles.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Medium Chain Triglycerides Oil: in quart bottles; *MCT*® (Mead Johnson Nutritionals); (OTC)

MEDROXYPROGESTERONE ACETATE

(*me-drox-ee-proe-jess-te-rone*) Provera®

PROGESTIN

Prescriber Highlights

- Synthetic progestin used primarily to treat sexually dimorphic behavior problems such as roaming, inter-male aggressive behaviors, spraying, mounting, etc.; sometimes used to treat feline psychogenic dermatitis & alopecia
- Because of serious adverse effect profile, consider safer alternatives first
- Contraindications: Do not use in pre-pubescent cats or dogs, diabetics, pregnancy, pseudopregnant bitches, females in diestrus or with prolonged heat, uterine hemorrhage or discharge
- Adverse Effects: Increased appetite &/or thirst, depression, lethargy, personality changes, adrenocortical depression, mammary changes (including enlargement, milk production, & neoplasms), diabetes mellitus, pyometra, & temporary inhibition of spermatogenesis
- SC injection may cause permanent local alopecia, atrophy & depigmentation may occur
- Drug-lab (including pathology) interactions

Uses/Indications

In cats, MPA has been used when either castration is ineffective or undesirable to treat sexually dimorphic behavior problems such as roaming, inter-male aggressive behaviors, spraying, mounting, etc. MPA has also been used as a tranquilizing agent to treat syndromes such as feline psychogenic dermatitis and alopecia, but treatment with “true” tranquilizing agents may be preferable.

In humans, parenteral MPA has been used as a long-acting contraceptive in females, to decrease sexually deviant behavior in males, and as an antineoplastic agent for some carcinomas (see Pharmacology section above). Oral MPA is used in human females to treat secondary amenorrhea and to treat abnormal uterine bleeding secondary to hormone imbalances.

Pharmacology/Actions

Progestins are primarily produced endogenously by the corpus luteum. They transform proliferative endometrium to secretory endometrium, enhance myometrium hypertrophy and inhibit spontaneous uterine contraction. Progestins have a dose-dependent inhibitory effect on the secretion of pituitary gonadotropins and can have an anti-insulin effect. Medroxyprogesterone has exhibited a pronounced adrenocorticoid effect in animals (species not listed) and can suppress ACTH and cortisol release. MPA is anti-estrogenic and will also decrease plasma testosterone levels in male humans and dogs.

MPA has antineoplastic activity against endometrial carcinoma and renal carcinoma (efficacy in doubt) in human patients. The mechanism for this activity is not known.

Pharmacokinetics

No specific pharmacokinetic parameters in veterinary species were located for this drug. It has been reported (Beaver 1989) that injectable MPA has an approximate duration of action of 30 days when used to treat behavior disorders in cats. When administered IM to women, MPA has contraceptive activity for at least 3 months.

Contraindications/Precautions/Warnings

Progestagen therapy can cause serious adverse effects (see below). Safer alternative treatments should be considered when possible, otherwise, weigh the potential risks versus benefits before instituting therapy. Many clinicians believe that progestogens are grossly overused.

Do not use MPA prior to puberty in cats, as chronic, severe, mammary hypertrophy may result. Use in dogs before puberty may precipitate subclinical uterine or endocrine conditions (e.g., cystic endometrial hyperplasia-pyometra; diabetes).

This agent should not be used during pregnancy or to treat bitches with pseudo-pregnancy. Females should not be treated during diestrus, or with uterine hemorrhage. Do not use in females with prolonged heat unless cystic ovarian disease is confirmed and surgery or GNRH or hCG are not viable options. Animals with diabetes should not receive medroxyprogesterone.

Because this drug can suppress adrenal function, exogenous steroids may need to be administered if the patient is stressed (e.g., surgery, trauma).

When used for reproductive control, patients should **1**) undergo a thorough reproductive history to rule out occurrence of estrus within the last 1–2 months (female in diestrus); **2**) complete physical exam; **3**) palpation of mammary glands to rule out mammary nodules; **4**) vaginal smear to rule out presence of estrus (Romagnoli 2002b)

Adverse Effects

If MPA is administered subcutaneously, permanent local alopecia, atrophy, and depigmentation may occur. If injecting SC, it is recommended to use the inguinal area to avoid these manifestations. Adverse reactions that are possible in dogs and cats include: increased appetite and/or thirst, depression, lethargy, personality changes, adrenocortical depression, mammary changes (including enlargement, milk production, and neoplasms), diabetes mellitus, pyometra, and temporary inhibition of spermatogenesis. In dogs, acromegaly and increased growth hormone levels have been seen when used in patients with diabetes mellitus.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **X** for use during pregnancy—especially the first 4 months: (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*)

Medroxyprogesterone can be detected in maternal milk, but in humans, no adverse effects in nursing infants have been noted.

Overdosage/Acute Toxicity

No reports or information was located on inadvertent overdosage with this agent. Refer to the Adverse Effects section above.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving medroxyprogesterone and may be of significance in veterinary patients:

- **AMINOGLUTETHIMIDE:** May decrease medroxyprogesterone effects
- **FELBAMATE:** May increase medroxyprogesterone metabolism
- **RIFAMPIN:** A potential interaction exists with rifampin, which may decrease progestin activity if administered concomitantly. This is presumably due to microsomal enzyme induction with resultant increase in progestin metabolism. The clinical significance of this potential interaction is unknown.

Laboratory Considerations

- In humans, progestins in combination with estrogens (e.g., oral contraceptives) have been demonstrated to increase thyroxine-binding globulin (TBG) with resultant increases in total circulating thyroid hormone. Decreased T₃ resin uptake also occurs, but free T₄ levels are unaltered. Liver function tests may also be altered.
- The manufacturer recommends notifying the pathologist of patient medroxyprogesterone exposure when submitting relevant specimens.

Doses

■ DOGS:

- a) For progestin-responsive dermatitis: 20 mg/kg IM; May repeat in 3–6 months if needed (Kunkle 1986)
- b) For adjunctive treatment of aggressive behaviors: 10 mg/kg IM or SC (see Adverse Effects above) as necessary; works best when combined with behavior modification. To treat inter-male aggression: as above, but do not exceed 3 treatments per year. (Voith and Marder 1988a)
- c) For long-term reproductive control: 2.5–3 mg/kg IM q5 months (Romagnoli 2002b), (Romagnoli 2006a)
- d) For treatment of young German shepherd dwarfs: medroxyprogesterone acetate at 2.5–5 mg/kg initially at 3 week intervals and subsequently at 6 week intervals has resulted in some increase in body size and development of an adult hair coat. (Kooistra 2006)
- e) For treatment of benign prostatic hypertrophy; best used to maintain breeding potential for short time prior to castration; use with caution: MPA at 0.3 mg/kg SC once; effects last approximately 10 months. (Lane 2006b)

■ CATS:

- a) To treat behavioral disorders: To reduce marking in neutered male cats when all other drugs have been unsuccessful: Medroxyprogesterone acetate at 5–20 mg/kg SC or IM three to four times yearly. (Landsberg 2007)
- b) For feline psychogenic alopecia and dermatitis: 75–150 mg IM or SC (see Adverse Effects above); repeat as necessary, but never more often than every 2–3 months (Walton 1986)
- c) For progestagen-responsive dermatitis: 50–100 mg IM; may repeat in 3–6 months if needed (Kunkle 1986)
- d) To treat recurrent abortion secondary to progesterone-deficiency: 1–2 mg/kg IM once weekly, stop treatment 7–10 days prior to parturition (Barton and Wolf 1988)

For long-term reproductive control:

- a) 2.5–5 mg PO once weekly; 25 mg injected every 6 months to postpone estrus (Henik, Olson, and Rosychuk 1985)
- b) 2 mg/kg IM q5 months (Romagnoli 2002b), (Romagnoli 2006a)

■ BIRDS:

- a) As an antipruritic and to suppress ovulation: 0.025–1 mL (3 mg/100 grams body weight) IM once every 4–6 weeks. May cause obesity, fatty liver, polydipsia/polyuria and lethargy if used repeatedly. (Clubb 1986)

Monitoring

- Weight
- Blood glucose (draw baseline before therapy)
- Mammary gland development
- Adrenocortical function
- Efficacy

Chemistry/Synonyms

A synthetic progestin, medroxyprogesterone acetate (MPA) occurs as an odorless, white to off-white, crystalline powder. It is insoluble in water and sparingly soluble in alcohol. It has a melting range of 200°–210°C.

Medroxyprogesterone acetate may also be known as: MPA, MAP, acetoxymethylprogesterone, medroxyprogesteroni acetat, methylacetoxypregesterone, metipregnone, and NSC-26386; many trade names are available.

Storage/Stability

Medroxyprogesterone acetate suspensions for injection should be stored at room temperature (15–30°C); avoid freezing and temperatures above 40°C. MPA tablets should be stored in well-closed containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Medroxyprogesterone Acetate Tablets (scored): 2.5 mg, 5 mg & 10 mg; *Provera*® (Pharmacia & Upjohn); generic; (Rx)

Medroxyprogesterone Acetate Injection: 104 mg (160 mg/mL) in 0.65 mL prefilled syringes & 1 mL vials; 150 mg/mL in 1 mL; 400 mg/mL in 2.5 mL and 10 mL vials and 1 mL U-ject; *Depo-Sub Q Provera 104*® (Pfizer); *Depo-Provera*® (Pharmacia); (Rx)

MEGESTROL ACETATE

(me-jess-trole) Ovaban®, Megace®

PROGESTIN

Prescriber Highlights

- **Synthetic progestin used in DOGS (FEMALE):** for postponement of estrus & the alleviation of false pregnancy; **DOGS (MALE):** benign prostatic hypertrophy. **CATS:** Many dermatologic & behavior-related conditions
- **Contraindications:** Pregnant animals or with uterine disease, diabetes mellitus, or mammary neoplasias; should not be used treat bitches with pseudo-pregnancy; females should not be treated during diestrus, or with uterine hemorrhage
- **Caution:** Thrombophlebitis
- **Adverse Effects:** **CATS:** Profound adrenocortical suppression, adrenal atrophy, transient diabetes mellitus, polydipsia/polyuria, personality changes, increased weight, endometritis, cystic endometrial hyperplasia, mammary hypertrophy, neoplasias, & hepatotoxicity possible. **DOGS:** Increased appetite & weight gain, lethargy, change in behavior or hair color, mucometra, endometritis, cystic endometrial hyperplasia, mammary enlargement & neoplasia, acromegaly, adrenocortical suppression, or lactation (rare)

Uses/Indications

Megestrol acetate (*Ovaban*®—Schering) is approved by FDA for use in dogs only for the postponement of estrus and the alleviation of false pregnancy. In male dogs, it has been used for benign prostatic hypertrophy. It is used clinically for many dermatologic and behavior-related conditions, primarily in the cat. See the Dosage section for specific indications and dosages for both dogs and cats.

Megestrol acetate is indicated in humans for the palliative treatment of advanced carcinoma of the breast or endometrium.

Pharmacology/Actions

Megestrol acetate possesses the pharmacologic actions expected of the other progestationals discussed (*e.g.*, medroxyprogesterone acetate). It has significant anti-estrogen and glucocorticoid activity (with resultant adrenal suppression). It does not have anabolic or masculinizing effects on the developing fetus.

Pharmacokinetics

Megestrol acetate is well absorbed from the GI tract and appears to be metabolized completely in the liver to conjugates and free steroids.

The half-life of megestrol acetate is reported to be 8 days in the dog.

Contraindications/Precautions/Warnings

Megestrol acetate is contraindicated in pregnant animals or in animals with uterine disease, diabetes mellitus, or mammary neoplasias. It has been recommended that MA not be used in dogs prior to their first estrous cycle or for anestrus therapy in dogs with abnormal cycles. The manufacturer (Schering) recommends that mating be prevented should estrus occur within 30 days of cessation of MA therapy.

This agent should not be used during pregnancy or to treat bitches with pseudo-pregnancy. Females should not be treated during diestrus, or with uterine hemorrhage. Do not use in females with prolonged heat unless cystic ovarian disease is confirmed and surgery or GNRH or hCG are not viable options. Animals with diabetes should not receive megestrol.

Because this drug can suppress adrenal function, exogenous steroids may need to be administered if the patient is stressed (e.g., surgery, trauma).

For estrus control, the manufacturer recommends that drug must be given for the full treatment regimen to be effective. The package insert states that “Ovaban® should not be given for more than two consecutive treatments,” but the reasons for this are unclear; some theriogenologists question the need for this precaution.

In humans, megestrol acetate is to be used with caution in patients with thrombophlebitis and is contraindicated as a test for pregnancy.

Adverse Effects

In cats, megestrol acetate can induce a profound adrenocortical suppression, adrenal atrophy, and an iatrogenic “Addison’s” syndrome can develop at “standard” dosages (2.5–5 mg every other day) within 1–2 weeks. Once the drug has been discontinued, serum cortisol levels (both resting and ACTH-stimulated) will return to normal levels within a few weeks. Clinical signs of adrenocortical insufficiency (e.g., vomiting, lethargy) are uncommon, but exogenous steroid support should be considered if the animal is stressed (surgery, trauma, etc.). Cats may develop a transient diabetes mellitus while receiving MA. Polydipsia/polyuria, personality changes, increased weight, endometritis, cystic endometrial hyperplasia, mammary hypertrophy and neoplasias may also occur. Increased appetite and weight gain is not consistently seen, but MA is occasionally used as an appetite stimulant. Rarely, megestrol acetate can cause hepatotoxicity (increased alkaline phosphatase) in cats.

Limited clinical studies have suggested that megestrol acetate may cause less cystic endometrial hyperplasia than other progestational agents, but cautious use and vigilant monitoring is still warranted.

In dogs, increased appetite and weight gain, lethargy, change in behavior or hair color, mucometra, endometritis, cystic endometrial hyperplasia, mammary enlargement and neoplasia, acromegaly, adrenocortical suppression or lactation (rare) may occur. One dog reportedly developed diabetes mellitus after use.

Reproductive/Nursing Safety

No effects were noted in either the bitch or litter when pregnant dogs received 0.25 mg/kg/day for 32 days during the first half of pregnancy; reduced litter sizes and puppy survival were detected when the dose was given during the last half of pregnancy. Fetal hypospadias are possible if progestational agents are administered during pregnancy.

During the *first 4 months of pregnancy* in humans, the FDA categorizes this drug as category **X** for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) During the *last 5 months of pregnancy* in humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Detectable amounts of progestins enter the milk of mothers receiving these agents. Effects on nursing infants have not been established.

Overdosage/Acute Toxicity

No information was located regarding acute overdosage of megestrol acetate. In humans, dosages of up to 800 mg/day caused no observable adverse reactions.

Toxicity studies performed in dogs at dosages of 0.1–0.25 mg/kg/day PO for 36 months yielded no gross abnormalities in the study population. Histologically, cystic endometrial hyperplasia was noted at 36 months, but resolved when therapy was discontinued. At dosages of 0.5 mg/kg/day PO for 5 months, a reversible uterine hyperplasia was seen in treated dogs. Dosages of 2 mg/kg/day demonstrated early cystic endometritis in biopsies done on dogs at 64 days.

Drug Interactions

■ **CORTICOSTEROIDS:** Megestrol used with corticosteroids (long-term) may exacerbate adrenocortical suppression and diabetes mellitus.

■ **RIFAMPIN:** May decrease progestin activity if administered concomitantly. This is presumably due to microsomal enzyme induction with resultant increase in progestin metabolism. The clinical significance of this potential interaction is unknown.

Doses

■ DOGS:

For estrus control:

- To halt cycle in proestrus: 2.2 mg/kg once daily for 8 days starting during the first 3 days of proestrus. While the timing of the next cycle is variable, it may be prolonged with 2.2 mg/kg/day for 4 days, then 0.55 mg/kg/day for 16–20 days.

To postpone an anticipated cycle: 0.55 mg/kg/day for 32 days, beginning at least 7 days prior to proestrus (Burke 1985)

- For suppression during proestrus (first 3 days): 2.2 mg/kg once daily for 8 days (92% efficacy). Bitch must be controlled until behavioral signs of estrus disappear. If mating occurs during first 3 days of therapy, stop treatment and consider mismating therapy. There is an increased likelihood of pyometra developing if progestins are used concomitantly with estrogens. If mating occurs after 3 or more days of therapy continue at a dosage rate of 3–4 mg/kg PO.

To delay an anticipated heat during anestrus: 0.55 mg/kg PO for 32 days initiated 7 days prior to proestrus. Recommend doing vaginal cytology prior to therapy. If no erythrocytes are seen, initiate therapy if cycle time frame is appropriate. If erythrocytes are seen, delay therapy until proestrus therapy can be instituted. Do not repeat therapy more often than once every 6 months. (Woody 1988)

- 2 mg/kg (or less) administered for ≤2 weeks in proestrus, or ≤2 mg/kg administered for a longer duration in anestrus. A typical dose for estrus suppression is 2 mg/kg PO once daily for 8 consecutive days, while a typical dose for temporary postponement is 0.5 mg/kg PO once daily in late anestrus. (Romagnoli 2002b), (Romagnoli 2006a)

For benign prostatic hypertrophy:

- 0.5 mg/kg PO daily for 4–8 weeks (Root Kustritz and Klausner 2000)
- 0.55 mg/kg PO daily (Purswell 1999)
- 0.1–0.5 mg/kg per day for 3–8 weeks; best used to maintain breeding potential for short time prior to castration; use with caution. (Lane 2006b)

For pseudocyesis (false pregnancy):

- 0.5 mg/kg PO once daily for 8 days (Barton and Wolf 1988)

To prevent vaginal hyperplasia development:

- 2.2 mg/kg PO for 7 days early in proestrus (Wykes 1986)

For treatment of severe galactorrhea:

- a) 0.55 mg/kg PO once daily for 7 days (Olson and Olson 1986)

For behavior disorders:

- a) For adjunctive treatment of aggressive or unacceptable masculine behavior: 1.1–2.2 mg/kg PO once daily for 2 weeks, then 0.5–1.1 mg/kg once daily for 2 weeks. Should be used with behavior modification. (Voith and Marder 1988a)

■ CATS:

For suppression of estrus:

- a) In anestrus: 5 mg/cat PO every 2 weeks or 2.5 mg/cat per week (better if divided into 2 doses given every 3.5 days); In proestrus: 5 mg/cat per day for 4 days, then 5 mg PO every 2 weeks. (Romagnoli 2006a)

- b) If in behavioral estrus, signs may be inhibited by giving 5 mg/day PO until estrus stops (generally within 3–5 days), then 2.5–5 mg PO once weekly for 10 weeks

Postponement of estrus (if started during diestrus): 2.5 mg PO daily for 8 weeks

Postponement of estrus (if started during anestrus): 2.5 mg PO once weekly for up to 18 months. Recommend allowing cat to have a cycle (unmedicated) before beginning another treatment cycle. (Woody 1988)

- c) If started in diestrus: 2.5 mg per day PO for up to 2 months
If started in anestrus: 2.5 mg per week for up to 18 months
For prevention of estrus: 5 mg daily PO for 3 days as soon as behavioral signs of estrus are seen; next estrus period will occur in approximately 4 weeks (Romatoski 1989) (information from package insert; *Ovarid*®—Glaxovet)

For treatment of idiopathic feline miliary dermatitis:

- a) 2.5–5 mg once every other day, followed by weekly maintenance dosages. May be necessary to treat for animal's lifetime. Reserve use for severe cases; explain risks to owner and do not exceed 2.5 mg per week during maintenance phase. (Kwochka 1986)

As appetite stimulant:

- a) 0.25–0.5 mg/kg q24h for 3–5 days, then q48–72h (Smith 2003a)

As an alternative treatment for immune-mediated skin diseases:

- a) 2.5–5 mg PO once daily for 10 days, then every other day (Giger and Werner 1988)

For adjunctive therapy of eosinophilic granulomas:

- a) 0.5 mg/kg PO once daily for 2 weeks, then twice weekly as needed (Coppoc 1988)

For eosinophilic ulcers:

- a) Alone or in combination with methylprednisolone acetate (*Depo-Medrol*®): 5–10 mg PO every other day for 10–14 doses, then every 2 weeks as needed (DeNovo, Potter, and Woolfson 1988)

For eosinophilic keratitis (feline proliferative keratitis):

- a) 0.5 mg/kg PO daily until a response is noted, then reduce dose to 1.25 mg PO 2–3 times weekly as required (Nelson 1986)

For feline plasma cell gingivitis:

- a) 2.5 mg PO once daily for 10 days, then once every other day for 5 treatments, then as needed (Morgan 1988)

As a secondary therapy (thyroid hormone replacement first choice) for treatment of feline endocrine alopecia (FEA):

- a) 5 mg PO every second to third day initially, then 2.5 mg PO once to twice weekly (Thoday 1986)

For feline psychogenic alopecia and dermatitis:

- a) 2.5–5 mg every other day initially, then taper to the lowest maintenance dosage possible, given weekly as needed (Walton 1986)

For adjunctive therapy (with urine acidification, increased urine crystalloid solubility, and antispasmodics if required) for persistent hematuria and urethritis in a non-obstructed cat:

- a) 2.5–5 mg PO once daily to every other day (with prednisone: 2.5–5 mg PO daily) (Lage, Polzin, and Zenoble 1988)

For urine marking, intraspecies aggression, anxiety:

- a) 2 mg/kg/day for 5 days, then 1 mg/kg/day for 5 days, then 0.5 mg/kg/day for 5 days (Romatoski 1989) (information from package insert; *Ovarid*®—Glaxovet)
- b) To reduce marking in neutered male cats when all other drugs have been unsuccessful: megestrol acetate at 2.5–10 mg (total dose) per cat PO once daily for one week, then reduce to once or twice weekly. (Landsberg 2007)

Monitoring

- Weight
- Blood glucose (draw baseline before therapy)
- Mammary gland development and appearance
- Adrenocortical function
- Liver enzymes if long-term treatment
- Efficacy

Client Information

- The client should fully understand the potential risks of therapy (see Adverse Effects above) before starting therapy and should report changes in mammary glands or other signs associated with adverse reactions (e.g., PU/PD, extreme lethargy, behavior changes, etc.) to the veterinarian.

Chemistry/Synonyms

A synthetic progestin, megestrol acetate (MA) occurs as an essentially odorless, tasteless, white to creamy white, crystalline powder that is insoluble in water, sparingly soluble in alcohol, and slightly soluble in fixed oils. It has a melting range of 213°–219°C over a 3° range and a specific rotation of +8° to +12°.

Megestrol acetate may also be known as: BDH-1298, compound 5071, megestroli acetate, NSC-71423, SC-10363, *Acestral*®, *Borea*®, *Endace*®, *Gynodal*®, *Maygace*®, *Megace*®, *Megastrol*®, *Megefren*®, *Megestat*®, *Megestil*®, *Megestin*®, *Megostat*®, *Meltonar*®, *Meprgest*®, *Mestrel*®, *Nia*®, *Niagestin*®, *Niagestine*®, *Ovaban*®, *Prazoken*®, and *Varigestrol*®.

Storage/Stability

Megestrol acetate tablets should be stored in well-closed containers at a temperature of less than 40°C. The tablets may be crushed and administered with food. The veterinary manufacturer recommends storing the tablets from 2°–30°C (36°–86°F).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Megestrol Acetate Oral Tablets: 5 mg, 20 mg; available in bottles of 250 and 500 tablets, and in 30 foil strips of 8 and packaged in cartons of 240 tablets; *Ovaban*® (Schering-Plough); (Rx). Approved for use in dogs only.

HUMAN-LABELED PRODUCTS:

Megestrol Acetate Tablets: 20 mg & 40 mg; *Megace*® (Bristol-Meyers Oncology); generic; (Rx)

Megestrol Acetate Suspension: 40 mg/mL in 240 mL; 125 mg/mL in 150 mL; *Megace*® (Bristol-Meyers Oncology); *Megace ES*® (Par Pharmaceutical Inc); (Rx)

MEGLUMINE ANTIMONIATE

(meg-loo-meen an-tih-mohne-ee-ate)

Glucantime®, Glucantim®

PENTAVALENT ANTIMONY ANTILEISHMANIAL

Prescriber Highlights

- ▶ Pentavalent antimony compound used for treating leishmaniasis (with or without allopurinol) in dogs
- ▶ Not available in USA
- ▶ Extreme caution (relatively contraindicated) in patients with cardiac, hepatic or renal insufficiency
- ▶ Primary adverse effects noted in dogs with meglumine antimoniate are injection site reactions, lethargy & gastrointestinal effects (inappetance, vomiting)
- ▶ Treatment is prolonged & cost may be substantial

Uses/Indications

Meglumine antimoniate is used alone or in combination with allopurinol to treat leishmaniasis in dogs. It is available commercially in some Mediterranean and South American countries but not in the USA.

Pharmacology/Actions

Pentavalent antimony compounds such as meglumine antimoniate and sodium stibogluconate selectively inhibit the leishmanial enzymes required for glycolytic and fatty acid oxidation. Pentavalent antimony compounds rarely are successful in eradicating *Leishmania* organisms completely in infected dogs.

Pharmacokinetics

After subcutaneous or intramuscular injections in dogs systemic bioavailability is about 92%; highest tissue concentrations are found in the liver, spleen, and skin. Within 9 hours of dosing, 80% of the antimony is excreted in the urine.

Contraindications/Precautions/Warnings

Patients with renal, hepatic or cardiac failure are more likely to develop serious adverse effects with this agent; weigh the potential risks versus benefits carefully before treating. Hypersensitivity reactions have been reported in people, and any patient with previous hypersensitivity to meglumine antimoniate should not receive the drug.

Adverse Effects

Primary adverse effects noted in dogs are injection site reactions, lethargy, and gastrointestinal effects (inappetance, vomiting). Transient increases in liver enzymes have been reported.

In humans, increased serum lipase, amylase, creatinine, urea nitrogen, and increased QT interval on ECG, have been reported. Occasionally, decreases in white blood cell counts and hemoglobin have been reported in humans.

Reproductive/Nursing Safety

There is limited information available. Pregnant rats given up to 300 mg/kg on days 6–15 caused increased fetal resorptions and increased rates of abnormalities of the atlas bone. Weigh the risks versus benefits when deciding to treat during pregnancy. It is unknown if the drug enters maternal milk.

Overdosage/Acute Toxicity

No specific overdose information was located. Depending on the dosage, a single overdose could potentially cause renal, hepatic, pancreatic, and hematologic effects, but gastrointestinal effects (vomiting) and lethargy would be the most likely outcomes. It is recommended to observe the patient and contact an animal poison control center for further guidance with an overdose situation.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving meglumine antimoniate and may be of significance in veterinary patients (dogs):

- **AGENTS THAT CAN PROLONG QT INTERVAL** (e.g., **tricyclic antidepressants, disopyramide, quinidine, procainamide**, etc.): meglumine antimoniate may prolong QT interval further with increased risk for arrhythmias

Laboratory Considerations

No specific laboratory interactions or considerations noted

Doses

■ DOGS:

For leishmaniasis:

- a) Meglumine antimoniate at a minimum dosage of 100 mg/kg SC daily for 3–4 weeks; better results are obtained with longer durations (4–6 weeks) of treatment. Protocol with allopurinol may reduce relapse rates: meglumine antimoniate as above with allopurinol at 20–40 mg/kg PO daily for a minimum of 3 weeks. Followed with long-term treatment with allopurinol (alone) at 20–40 mg/kg PO daily or intermittently (one week treatment per month). (Noli and Auxilia 2005)
- b) Meglumine antimoniate (100 mg/kg/day SC) until resolution; with allopurinol at 20 mg/kg PO q12h for 9 months. (Brosey 2005)

Monitoring

- Efficacy (PCR preferred)
- CBC (baseline and periodic)
- Liver enzymes; renal function tests (serum creatinine, BUN); serum lipase and amylase (baseline and periodic)
- Urinalysis (baseline and periodic)

Client Information

- Clients should understand that treatment with this drug can be prolonged and expensive, and that a “cure” (complete eradication) is unlikely

Chemistry/Synonyms

Meglumine antimoniate is 1-Deoxy-1-methylamino-D-glucitol antimoniate. It has a molecular weight of 366. One gram contains approximately 272 mg of antimony.

Meglumine antimoniate may also be known as: meglumine antimonate, N-methylglucamine antimoniate, RP-2168, antimony meglumine, Protostib, 1-Deoxy-1-methylamino-D-glucitol antimoniate, *Glucantime*® and *Glucantim*®.

Storage/Stability

Unless otherwise specified by the manufacturer, commercially available ampules should be stored below 40°C, preferably between 15°–30°C; protect from freezing.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None in the USA.

HUMAN-LABELED PRODUCTS: None in the USA

Meglumine antimoniate may be available in several countries, including Brazil, France, Italy, Spain and Venezuela; trade names include: *Glucantime*® and *Glucantim*®. Commercially it is available as a solution containing 1.5 grams of meglumine antimoniate (425 mg pentavalent antimony) per 5 mL.

The FDA may allow legal importation of this medication for compassionate use in animals; for more information, see the *Instructions for Legally Importing Drugs for Compassionate Use in the USA* found in the appendix.

MELARSOMINE

(mee-lar-soe-meen) Immiticide®

ARSENICAL ANTIPARASITIC

Prescriber Highlights

- ▶ Organic arsenical for heartworm disease
- ▶ Contraindications: Class IV (very severe) heartworm disease; weigh risk vs. potential benefits in pregnant, lactating, or breeding dogs
- ▶ Reportedly very toxic to cats; not currently recommended
- ▶ Adverse Effects: Many possible, most common are: Injection site reactions coughing/gagging, depression/lethargy, anorexia/inappetence, excessive salivation, fever, lung congestion, vomiting, pulmonary thromboembolism
- ▶ Special IM injection technique; do not give IV or SC
- ▶ Avoid human exposure
- ▶ Calculate dosages very carefully

Uses/Indications

Melarsomine is indicated for the treatment of stabilized class I, II, and III heartworm disease caused by immature (4 month old, stage L5) to mature adult infections of *D. immitis* in dogs. When compared with thiacetarsamide, melarsomine appears to be more efficacious, less irritating to tissues, and does not cause hepatic necrosis.

Melarsomine may also be useful for treating ferrets; it has been suggested to contact the manufacturer before using the drug in this species.

Pharmacology/Actions

While melarsomine is an arsenical compound, its exact mechanism of action is not known. Both laboratory and field studies have demonstrated that melarsomine is 90–99% effective in killing adult and L5 larvae of *D. immitis* in dogs at recommended dosages.

Pharmacokinetics

Melarsomine is reportedly rapidly absorbed after IM injection in dogs; time to peak plasma concentration is about 11 minutes. The apparent volume of distribution is about 0.7 L/kg; terminal half-life is approximately 3 hours.

Contraindications/Precautions/Warnings

Melarsomine is contraindicated in dogs with class IV (very severe) heartworm disease. Class IV is having caval syndrome (heartworms present in venae cavae and right atrium). Melarsomine is reportedly very toxic to cats and its use cannot be recommended for this species at this time.

Older dogs (>8 years) may be more susceptible to adverse effects than younger dogs.

Do NOT give IV or SC; significant toxicity or tissue damage may occur. Administer only deep IM as directed (lumbar epaxial muscles (L3-L5). Do not administer at any other site.

While all dogs with heartworm disease are at risk for post-treatment pulmonary thromboembolism, those with severe pulmonary artery disease are at increased risk for post treatment morbidity and mortality. Dogs should be exercise restricted after treatment.

Wash hands after use or wear gloves. Avoid drug contact with animal's eyes; if exposed wash with copious amounts of water. Avoid human exposure. If human exposure occurs, contact a physician.

Adverse Effects

Approximately 1/3 of dogs show signs of injection site reactions (pain, swelling, tenderness, reluctance to move) after receiving melarsomine. Most of these signs resolve within weeks, but, rarely, severe injection reactions can occur. Firm nodules at the injection site can persist indefinitely. SC or IV injections must be avoided. The most severe local reactions are usually seen if the drug leaks back from the injection site into subcutaneous tissues. Applying firm pressure to the injection site after administration may reduce the risk for this problem.

Other reactions reported in 5% or more dogs treated include: coughing/gagging (22% incidence; average day of onset after treatment = 10); depression/lethargy (15% incidence; average day of onset after treatment = 5); anorexia/inappetence (13% incidence; average day of onset after treatment = 5); fever (7%); lung congestion (6%); vomiting (5%). There is significant interpatient variance in both the date of onset and duration for the above effects. Dogs may also exhibit excessive salivation after dosing.

There are a plethora of other adverse effects in dogs with reported incidences less than 3%, including paresis and paralysis. Refer to the package insert for specifics.

Animals not exhibiting adverse effects after the first dose or course of therapy may demonstrate them after the second dose or course of therapy.

Reproductive/Nursing Safety

Safety has not been established for use in pregnant, lactating, or breeding dogs. Risks versus potential benefits of therapy should be weighed before use.

Overdosage/Acute Toxicity

There is low margin of safety with melarsomine dosages. A 3X dose (7.5 mg/kg) in healthy dogs have demonstrated respiratory inflammation and distress, excessive salivation, restlessness, panting, vomiting, edema, tremors, lethargy, ataxia, cyanosis, stupor, and death. Signs of diarrhea, excessive salivation, restlessness, panting, vomiting, and fever have been noted in infected dogs that have received inadvertent overdoses (2X).

Treatment with dimercaprol (BAL in Oil) may be considered to treat melarsomine overdoses. Clinical efficacy of melarsomine may be reduced, however.

Drug Interactions

The manufacturer reports that during clinical field trials, melarsomine was given to dogs receiving antiinflammatory agents, antibiotics, insecticides, heartworm prophylactic medications, and various other drugs commonly used to stabilize and support dogs with heartworm disease and that no adverse drug interactions were noted.

- **ASPIRIN:** Has been shown not to reduce adverse effects and may complicate therapy; use is not recommended
- **CNS DEPRESSANT DRUGS:** Drugs that have similar adverse effects (e.g., depression caused by CNS depressants, etc.) may cause additive adverse effects or increase their incidence when used with melarsomine

Doses

CAUTION: Because of the low margin of safety; calculate dosages very carefully. Do not confuse mg/lb with mg/kg!

■ DOGS:

For treatment of dirofilariasis it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information.

Immiticide® (Merial) product support phone number: 888-637-4251

For treatment of heartworm disease:

- a) After diagnosis, determine the class (stage) of the disease.
Note: The manufacturer provides worksheets that assist in the classification and treatment regime determination. It is highly recommended to use these treatment records to avoid confusion and document therapy.

Class I, & II: 2.5 mg/kg deep IM as directed (lumbar epaxial muscles [L3-L5] twice 24 hours apart and rest. Use alternating sides with each administration. In 4 months, the regimen may be repeated.

Class III: 2.5 mg/kg deep IM as directed (lumbar epaxial muscles [L3-L5]). Strict rest and give all necessary systemic treatment. One month later, give 2.5 mg/kg deep IM as directed (lumbar epaxial muscles [L3-L5] twice 24 hours apart.

Note: Recommended needle size for dogs 10 kg or less = 23 gauge 1 inch; 10 kg or more body weight = 22 gauge 1.5 inch. (Package Insert; *Immiticide*®—Merial)

- b) The three-injection alternative protocol [2.5 mg/kg deep IM as directed (lumbar epaxial muscles; L3-L5). Strict rest and give all necessary systemic treatment. One month later, give 2.5 mg/kg deep IM as directed (lumbar epaxial muscles; L3-L5) twice 24 hours apart] is the treatment of choice of the American Heartworm Society and several university teaching hospitals, regardless of stage of disease, due to the increased safety and efficacy benefits and subsequently fewer dogs that require further treatment with melarsomine. (American Heartworm Society; www.heartwormsociety.org; accessed 2007)

Monitoring/Client Information

- Clinical efficacy
- Adverse effects; dogs should be observed for 24 hours after the last injection
- Because of the seriousness of the disease and the potential for morbidity and mortality associated with the treatment, clients should give informed consent before electing to treat.

Chemistry/Synonyms

An organic arsenical compound, melarsomine dihydrochloride has a molecular weight of 501 and is freely soluble in water.

Melarsomine may also be known as *Immiticide*®. Its CAS registry is 128470-15-5.

Storage/Stability/Preparation

The unreconstituted powder should be stored upright at room temperature. Once reconstituted, the solution should be kept in the original container and kept refrigerated for up to 24 hours. Do not freeze. Do not mix with any other drug.

Reconstitute with 2 mL of the diluent provided (sterile water for injection) with a resultant concentration of 25 mg/mL. Once reconstituted, the solution should be kept in the original container and kept refrigerated for up to 24 hours. Do not freeze.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Melarsomine Dihydrochloride Powder for Injection: 50 mg/vial; *Immiticide*® (Merial); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS: None

MELATONIN

(mel-a-tone-in) Regulin®

HORMONE

Prescriber Highlights

- Oral & implantable pineal gland hormone
- Potential uses include: Alopecia in dogs, sleep & behavior disorders in cats & dogs, adjust seasonally controlled fertility in sheep, goats, & horses, & adjunctive treatment for adrenal disease in ferrets
- Adverse effects appear to be minimal, but little experience
- Potential contraindications include: Pregnancy, sexually immature animals, & liver dysfunction

Uses/Indications

Melatonin may be useful to treat Alopecia-X in Nordic breeds, canine pattern baldness, or canine recurrent flank alopecia in dogs. It has been used anecdotally for the treatment of sleep cycle disorders in cats and geriatric dogs and to treat phobias and separation anxiety in dogs. Melatonin implants are used in the mink and fox pelt industries to promote the development of luxurious hair coats. Implants are also used to improve early breeding and ovulation rates in sheep and goats. Preliminary research is being done for this purpose in horses also.

In pigs, one study (Bubenik, Ayles et al. 1998) demonstrated that 5 mg/kg in feed reduced the incidence of gastric ulcers in young pigs.

Pharmacology/Actions

Melatonin is involved with the neuroendocrine control of photoperiod dependent molting, hair growth and pelage color. Melatonin stimulates winter coat growth and spring shedding occurs when melatonin decreases. The mechanism of how melatonin induces these effects is not well understood. It may have direct effects on the hair follicle or alter the secretion of prolactin and/or melanocyte stimulating hormone.

Melatonin also increases serum prolactin levels, growth hormone, and increases response to growth hormone releasing hormone. Long-term use may decrease luteinizing hormone. Melatonin is also ostensibly a free radical scavenger.

Pharmacokinetics

No specific information was located.

Contraindications/Precautions/Warnings

Melatonin implants are considered contraindicated in pregnant or sexually immature animals. There are very specific times for administration depending on latitude, hemisphere, and breed. Animals that are nursing young may not benefit from implant therapy.

In humans, melatonin is considered contraindicated in patients with hepatic insufficiency as it is cleared hepatically. It is also contraindicated in patients with a history of cerebrovascular disease, depression or neurological disorders. Use caution in patients with renal impairment.

Adverse Effects

Melatonin appears to be quite safe in dogs. Side effects in dogs when given orally are rare but the hormone may cause sedation, and affect sex hormone secretion and fertility. Subcutaneous implants in dogs have been associated with sterile abscesses.

Adverse effects in ferrets have not been reported.

Adverse effects reported in humans include altered sleep patterns, hypothermia, sedation, tachycardia, confusion, headache, and pruritus.

Reproductive/Nursing Safety

No information was located; use with caution.

Overdosage/Acute Toxicity

Little information is available; unlikely to cause significant morbidity after a single overdose.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving melatonin and may be of significance in veterinary patients:

- **BENZODIAZEPINES:** Melatonin may potentiate effects
- **SUCCINYLCHOLINE:** Melatonin may potentiate effects

Doses

■ DOGS:

For dermatologic conditions:

- a) For experimental treatment of Alopecia-X in Nordic breeds, canine pattern baldness, or canine recurrent flank alopecia: Empirical dose of one to four 12 mg implants SC. Retreatment may be necessary once or twice a year. If implants are unavailable, oral melatonin at 3–6 mg every 8–12 hours may be tried. Although appears to be safe, recommend having owners sign a release form noting the “experimental” nature of treatment. (Paradis 2000)
- b) For treatment of canine recurrent flank alopecia or seasonal flank alopecia: 2–3 mg per dog PO once daily for 3–5 days weekly or monthly or this as a daily dose. Doses of up to 10 mg per dog have used. Improvement is usually seen in one month with maximal improvement in 3 months. (Merchant 2000)
- c) For treatment of Alopecia-X in Nordic breeds, Canine pattern baldness, or canine recurrent flank alopecia: 3 mg for dogs under 10 kg and 6 mg for dogs 10 kg or greater PO q8–12 hrs for 6 to 8 weeks. (Campbell 1999)

- d) For treatment of Alopecia-X: Empirical dose is 3 mg–12 mg (depending on the dog's size) PO 2 to 3 times a day. Perform a trial for at least 4 months before evaluating response; only reported side effect is drowsiness. (Torres 2007a)

For sleep disorders (nocturnal activity):

- a) 3–6 mg (total dose) PO q12–24h (Virga 2002)

■ CATS:

For sleep disorders (nocturnal activity):

- a) 3–12 mg (total dose) PO q12–24h (Virga 2002)

■ FERRETS:

For adjunctive treatment of adrenal disease:

- a) 0.5–1 mg per ferret PO once daily 7–9 hours after sunrise has been anecdotally effective in alleviating alopecia, aggressive behavior, vulvar swelling and prostatomegaly. Improvement more likely in patients with adrenal hyperplasia or adenoma; less likely if adenocarcinoma. Has no effect on tumor growth or metastasis. The implant form (5.4 mg) releases melatonin over a 3–4 month period. Response to melatonin, in general, is better in fall and winter. Can be used with other treatments (e.g., leuprolide, anastrozole, bicalutamide, finasteride). (Johnson 2006b)

Monitoring

- Clinical efficacy

Client Information

- For use in small animals, must be administered as directed to be effective.
- Relatively “experimental”; safety and efficacy are not clearly established.

Chemistry/Synonyms

A naturally occurring hormone produced in the pineal gland, melatonin occurs as a pale yellow, crystalline solid and has a molecular weight of 232. It can be derived from natural sources or by synthetic means.

Melatonin may also be known as: n-acetyl-5-methoxytryptamine, MEL, MLT, pineal hormone, *Benedorm*®, *Buenas Noches*®, *Cronocaps*®, *Dermatonin*®, *Ferretonin*®, *HT90*®, *Melapure*®, *MelatoI*®, *Regulin*®, *Repentil*®, *Revenox*®, and *Transzone*®.

Storage/Stability

Unless otherwise labeled, store at room temperature in tight containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Melatonin 5.4 mg implant product marketed for ferrets; *Ferretonin*® (Melatek); 1-877-635-2835; www.melatek. Approval status is not known

Melatonin 8 mg, 12 mg, 18 mg implant product marketed for dogs; *Dermatonin*® (Melatek); Approval status not known

An 18 mg implant for sustained subcutaneous release is available in a variety of countries. One trade name is *Regulin*®. It is labeled for use in sheep (UK and NZ) and goats (NZ) to improve early breeding and ovulation rates.

There reportedly are mink implants available in the United States from Neo-Dynamics (800-206-7227).

HUMAN-LABELED PRODUCTS:

Melatonin tablets are available in a variety of strengths from a variety of sources. Common strengths available range from 0.5 mg to 3 mg tablets. Sustained release capsules (3 mg) and oral liquid (500 mcg/mL) may also be available. Because melatonin is considered a “nutrient” there is no official labeling or central quality control systems for it in the USA. Purchase from reputable sources.

MELOXICAM

(mel-ox-i-kam) Metacam®

NONSTEROIDAL ANTIINFLAMMATORY AGENT**Prescriber Highlights**

- ▶ NSAID used in dogs & cats; COX-2 preferential
- ▶ Available as both an injectable & oral product
- ▶ GI adverse effects can occur

Uses/Indications

Meloxicam is principally used for the symptomatic treatment of osteoarthritis in dogs. Short-term (single dose injectable) use is also approved (in the USA) for cats for the control of postoperative pain and inflammation associated with orthopedic surgery, ovariohysterectomy and castration when administered prior to surgery.

Pharmacology/Actions

Meloxicam has antiinflammatory, analgesic, and antipyretic activity similar to other NSAIDs. Like other NSAIDs, meloxicam exhibits analgesic, antiinflammatory, and antipyretic activity probably through its inhibition of cyclooxygenase, phospholipase A₂, and inhibition of prostaglandin synthesis. It is considered COX-2 preferential (not COX-2 specific) as at higher dosages its COX-2 specificity is diminished.

Acute dosing studies in dogs have not demonstrated any untoward renal or hepatic toxicity.

Pharmacokinetics

In dogs, meloxicam is well absorbed after oral administration. Food does not alter absorption. Peak blood levels occur in about 7–8 hours after administration. The volume of distribution in dogs is 0.3 L/kg and about 97% is bound to plasma proteins. Meloxicam is extensively biotransformed to several different metabolites in the liver; none of these appear to have pharmacologic activity. The majority of these (and unchanged drug) are eliminated in the feces. A significant amount of enterohepatic recirculation occurs. Elimination half-life is species specific. The elimination half-life in dogs averages 24 hours (range: 12–36 hours); other species: pigs: 4 hours; horses: 3 hours; cattle: 13 hours.

In cats, subcutaneous injection is nearly completely absorbed. Peak levels occur about 1.5 hours after injection. Meloxicam is relatively highly bound to feline plasma proteins (97%) and volume of distribution is about 0.27 L/kg. After a single dose, total systemic clearance is approximately 130 mL/hr/kg and elimination half life is approximately 15 hours.

Contraindications/Precautions/Warnings

Meloxicam is contraindicated in dogs hypersensitive to it. Safe use has not been evaluated in dogs less than 6 months old. The European label states that safe use has not been evaluated in dogs less than 6 weeks old. Although not part of the label, it should probably not be used in dogs with active GI ulceration or bleeding. It

should be used with caution in patients with impaired hepatic, cardiac or renal function and hemorrhagic disorders.

Meloxicam is contraindicated in cats with known hypersensitivity to meloxicam or other NSAIDs. The manufacturer warns that additional doses of meloxicam or other NSAIDs are contraindicated as no safe dosage for repeated NSAID administration has been established. Use in cats less than 4 months of age has not been established. Use preoperatively for cats undergoing major surgery where hypotensive episodes are possible; may be at higher risk for renal damage.

The human label states that no dosage adjustment is necessary in patients with mild to moderate hepatic or renal impairment. Use extreme caution in dehydrated, hypovolemic, or hypotensive animals as there is a potential increased risk of renal toxicity developing.

Adverse Effects

Experience in Europe and Canada has demonstrated a relatively safe adverse effect profile for meloxicam in dogs. GI distress is the most commonly reported adverse effect, and in US field trials vomiting, soft stools, diarrhea, and inappetence were the most common adverse effects reported. Renal toxicity appears to be quite low. Post-approval adverse effects reported have included GI effects (vomiting, anorexia, diarrhea, melena, ulceration), elevated liver enzymes, pruritus, azotemia, elevated creatinine, and renal failure.

In cats, single doses of meloxicam appear relatively safe. In field trials some cats developed elevated BUN, post-treatment anemia and, rarely, residual pain at the injection site. In other studies, meloxicam has caused GI effects (vomiting, diarrhea, inappetence), behavior changes, and lethargy. Repeated use of meloxicam in cats had been associated with renal failure and death.

Reproductive/Nursing Safety

Safe use has not been established in dogs or cats used for breeding, or in pregnant or lactating animals. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Most NSAIDs are excreted in milk; use cautiously.

Overdosage/Acute Toxicity

The manufacturer warns to prevent accidental overdosing in small dogs, and to administer drops on food and not directly into the mouth. Treat symptomatically and supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving meloxicam and may be of significance in veterinary patients:

- **ACE INHIBITORS** (e.g., enalapril, benazepril): Some NSAIDs can reduce effects on blood pressure
- **ANTICOAGULANTS** (e.g., heparin, warfarin, etc.): Increased chance for bleeding
- **ASPIRIN**: May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- **CORTICOSTEROIDS** (e.g., prednisone): May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)
- **DIGOXIN**: NSAIDs may increase serum levels
- **FLUCONAZOLE**: Administration has increased plasma levels of celecoxib in humans and potentially could also affect meloxicam levels in dogs

- **FUROSEMIDE:** NSAIDs may reduce saluretic and diuretic effects
- **METHOTREXATE:** Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution
- **NEPHROTOXIC DRUGS** (e.g., **furosemide**, **aminoglycosides**, **amphotericin B**, etc.): May enhance the risk of nephrotoxicity
- **NSAIDS, OTHER:** May increase the risk of gastrointestinal toxicity (e.g., ulceration, bleeding, vomiting, diarrhea)

Doses

When doses are listed in “drops” use with caution, as drug concentration per drop may be different in products marketed in various countries.

■ DOGS:

For approved indications (osteoarthritis, analgesia, inflammatory conditions):

- a) Initially 0.2 mg/kg PO, IV or SC on the first day of treatment, subsequent doses of 0.1 mg/kg PO once daily in food or placed directly into mouth (not when dosing by the drop). (Package Insert; *Metacam® Injection/Oral Suspension*)

■ CATS:

For pain:

- a) For labeled indications: 0.3 mg/kg SC once (Label information; *Metacam® Injection for Cats—BI*)

Note: The following dosages are extra-label in cats:

- b) 0.2 mg/kg PO initially, followed by 0.1 mg/kg PO (in food) once daily for 2 days and then 0.025 mg/kg 2–3 times a week (McLaughlin 2000)
- c) 0.1 mg/kg PO once daily (limit to 4 days use); 0.3 mg/kg IV or SC (one time use only) (Hardie 1997)
- d) For surgical pain: 0.2 mg/kg (or less) PO or SC once; 0.1 mg/kg (or less) SC, PO daily for 3–4 days
For chronic pain: 0.2 mg/kg (or less) PO, SC once; 0.1 mg/kg (or less) PO for 3–4 days; 0.025 mg/kg PO (0.1 mg maximum dose per cat) 2–3 times weekly (Mathews 2000)

■ RABBITS, RODENTS:

For musculoskeletal and mild visceral pain:

- a) 0.2 mg/kg PO or SC once daily. Has a duration of action for 24–48 hours in most species; may be used for prolonged periods of time; also very effective when used in combination with opioids. (Mayer 2007)

Monitoring

- Clinical efficacy
- Adverse effects
- Renal function and hepatic function if used chronically

Client Information

- Shake oral liquid well before using.
- Carefully measure dose (oral liquid); do not confuse the markings on the syringe (provided by the manufacturer) with mL or kgs. If using drops to measure dose in small dogs, do not place drops directly into dog's mouth; mix with food. Otherwise, may place oral syringe into dogs mouth or mix with food.
- If animal develops adverse effects, contact the veterinarian
- If dispensed for outpatient use, obtain client information sheet for this medication

Chemistry/Synonyms

A COX-2 receptor preferential NSAID, meloxicam occurs as a pale yellow powder. It is in the oxicam class, related to piroxicam.

Meloxicam may also be known as: UH-AC-62, and UH-AC-62XX; many trade names are available.

Storage/Stability

Unless otherwise labeled, store the injection and oral liquid at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Meloxicam Oral Suspension: 1.5 mg/mL (0.05 mg per drop in the USA product) in a honey-flavored base: 10 mL, 32 mL, 100 mL drop-per bottles with measuring syringe (marked in 5 lb body weight increments); *Metacam®* (Boehringer Ingelheim Vetmedica); (Rx). Approved for use in dogs.

Meloxicam 5 mg/mL for Injection: 10 mL vial; *Metacam® Injection for Dogs* (Boehringer Ingelheim Vetmedica); (Rx). Approved for use in dogs.

Meloxicam 5 mg/mL for Injection: 10 mL vial; *Metacam® Injection for Cats* (Boehringer Ingelheim Vetmedica); (Rx). Approved for use in cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Meloxicam Tablets: 7.5 mg & 15 mg; *Mobic®* (Boehringer Ingelheim/Abbott); generic; (Rx)

Meloxicam Oral Solution: 7.5 mg/5 mL in 100 mL; *Mobic®* (Boehringer Ingelheim/Abbott); Meloxicam (Roxane); (Rx)

In Canada, *Mobicox®* (Boehringer Ingelheim); (Rx)

MELPHALAN

(mel-fa-lan) Alkeran®

ANTINEOPLASTIC

Prescriber Highlights

- ▶ Alkylating agent antineoplastic used for ovarian carcinoma, lymphoreticular neoplasms, osteosarcoma, mammary or pulmonary neoplasms, & multiple myeloma
- ▶ Contraindications (relative; risk vs. benefit): Anemia, bone marrow depression, current infection, impaired renal function, tumor cell infiltration of bone marrow, sensitivity to drug, or patients who have received previous chemotherapy or radiotherapy
- ▶ Adverse Effects: GI effects (anorexia, vomiting, diarrhea), pulmonary infiltrates or fibrosis, bone marrow depression (anemia, thrombocytopenia, leukopenia)
- ▶ Potential teratogen
- ▶ Determine dosages carefully

Uses/Indications

Melphalan may be useful in the treatment of a variety of neoplastic diseases, including ovarian carcinoma, lymphoreticular neoplasms, osteosarcoma, and mammary or pulmonary neoplasms. When combined with prednisone, it is considered the drug of choice for treating multiple myeloma. It has been used successfully in a rescue protocol combining dexamethasone, melphalan, dactinomycin and cytarabine to treat relapsed multicentric lymphoma in dogs.

Pharmacology/Actions

Melphalan is a bifunctional alkylating agent and interferes with RNA transcription and DNA replication, thereby disrupting nucleic acid function. Because it is bifunctional, it has affect on both dividing and resting cells. Melphalan does not require activation by the liver (unlike cyclophosphamide).

Pharmacokinetics

Melphalan absorption is variable and often incomplete. It is distributed throughout the body water, but it is unknown whether it crosses the placenta, blood brain barrier or enters maternal milk. Melphalan is eliminated principally by hydrolysis in plasma. In humans, terminal half-lives average about 90 minutes.

Contraindications/Precautions/Warnings

Melphalan should be used with the following conditions only when its potential benefits outweigh its risks: anemia, bone marrow depression, current infection, impaired renal function, tumor cell infiltration of bone marrow, sensitivity to melphalan or patients who have received previous chemotherapy or radiotherapy.

Adverse Effects

Potential adverse effects include GI effects (anorexia, vomiting, diarrhea), and pulmonary infiltrates or fibrosis. The most serious adverse effect likely with melphalan is bone marrow depression (anemia, thrombocytopenia, leukopenia).

Reproductive/Nursing Safety

Safe use of melphalan during pregnancy has not been established; other alkylating agents are known teratogens. Use only during pregnancy when the benefits to the mother outweigh the risks to the offspring. Melphalan can suppress gonadal function.

While it is unknown whether melphalan enters maternal milk, nursing puppies or kittens should receive milk replacer when the bitch or queen is receiving melphalan.

Overdosage/Acute Toxicity

Because of the toxic potential of this agent, overdoses must be avoided. Determine dosages carefully.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving melphalan and may be of significance in veterinary patients:

- **CYCLOSPORINE:** There are anecdotal reports of melphalan causing increased nephrotoxicity associated with systemic cyclosporine use in humans.
- **IMMUNOSUPPRESSANT DRUGS** (e.g., **azathioprine**, **cyclophosphamide**, **corticosteroids**): Use with other immunosuppressant drugs may increase the risk of infection.
- **MYELOSUPPRESSIVE DRUGS** (e.g., **chloramphenicol**, **flucytosine**, **amphotericin B**, or **colchicine**): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs. Bone marrow depression may be additive.

- **VACCINES, LIVE:** Live virus vaccines should be used with caution, if at all, during therapy.

Laboratory Considerations

- Melphalan may raise serum **uric acid** levels. Drugs such as allopurinol may be required to control hyperuricemia.

Doses

For more information on using melphalan as part of chemotherapy protocols, refer to the protocols found in the appendix or other dosages/protocols found in numerous references, including: *Withrow and MacEwen's Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

■ DOGS:

As part of a rescue protocol (DMAC) to treat relapsed multicentric lymphoma:

- a) Dactinomycin (0.75 mg/m² IV), Cytarabine (300 mg/m² IV over 4 hours or SC) and dexamethasone (1 mg/kg PO) on day 0 and melphalan (20 mg/m² PO) and dexamethasone (1 mg/kg PO) on day 7. The cycle is repeated continuously every 2 weeks as long as a complete or partial remission is achieved. After four cycles, chlorambucil was substituted for melphalan at the same dose. If complete remission achieved, protocol was discontinued after 5–8 cycles and maintenance therapy with the LMP (chlorambucil, methotrexate, prednisone) or lomustine/prednisone protocols were instituted. If dogs developed grades 3 or 4 toxicosis, DMAC was discontinued and maintenance protocol was started. (Alvarez, Kisseberth et al. 2006), (Rassnick 2006)

For adjunctive treatment of ovarian carcinoma, multiply myeloma, lymphoreticular neoplasms, osteosarcoma, and mammary or pulmonary neoplasms:

- a) 2–4 mg/m² PO every 48 hours (every other day). 1.5 mg/m² PO every 24 hours (once daily) for 7–10 days (Jacobs, Lumsden et al. 1992)

For multiple myeloma (usually in combination with prednisone):

- a) 2 mg/m² once daily for 7–10 days, then 2–4 mg/m² PO every other day. Alternatively give 6–8 mg/m² PO for 4–5 days, repeated every 21 days. Used in combination with prednisone. (Kitchell and Dhaliwal 2000)
- b) 0.05–0.1 mg/kg PO once daily until remission, then every other day (Lana 2002)

For anal sac or apocrine gland adenocarcinomas:

- a) 2 mg/m² PO once daily for one week, then every other day (Peterson and Couto 1994)

■ CATS:

For adjunctive treatment of FIP:

- a) Predniso(lo)ne 4 mg/kg PO once daily with melphalan 2 mg/m² (or about ¼ of a 2 mg tablet) once every 48 hours (Weiss 1994)

For chronic lymphocytic leukemia:

- a) 2 mg/m² PO every other day with or without prednisone at 20 mg/m² PO every other day (Peterson and Couto 1994)

Monitoring

- CBC with platelets at least every 1–2 weeks until stable

Client Information

- Clients must understand the importance of both administering melphalan as directed and immediately reporting any signs associated with toxicity (e.g., abnormal bleeding, bruising, urination, depression, infection, shortness of breath, etc.).

Chemistry/Synonyms

A nitrogen mustard derivative, melphalan occurs as an off-white to buff-colored powder that is practically insoluble in water.

Melphalan may also be known as: CB-3025, NSC-8806, PAM, L-PAM, L-phenylalanine mustard, phenylalanine mustard, phenylalanine nitrogen mustard, L-sarcosylsine, WR-19813, *Alkeran*® or *Alkerana*®.

Storage/Stability/Compatibility

Store melphalan tablets in well-closed, light-resistant, glass containers in the refrigerator (2–8°C). It is recommended to dispense the tablets in glass containers.

Once reconstituted, the injectable product should not be refrigerated or a precipitate may form. It is stable at room temperature for 90 minutes after reconstitution. For administration, the reconstituted solution should be further diluted with sterile 0.9% sodium chloride to a concentration of not more than 0.45 mg/mL. This diluted solution is stable for 60 minutes at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Melphalan Tablets: 2 mg; *Alkeran*® (Celgene); (Rx)

Melphalan Powder for Injection (lyophilized): 50 mg in single use vials with 10 mL vial of sterile diluent; *Alkeran*® (Celgene); (Rx)

MEPERIDINE HCL

(me-*per*-i-deen) Demerol®, Pethidine

OPIATE AGONIST

Prescriber Highlights

- ▶ Opiate analgesic; infrequently used as it has a short duration of analgesia & may cause more adverse effects than other commonly used injectable opiates
- ▶ Contraindications: Hypersensitivity to it, diarrhea caused by a toxic ingestion
- ▶ Extreme Caution: Respiratory disease or acute respiratory dysfunction
- ▶ Caution: Hypothyroidism, severe renal insufficiency, adrenocortical insufficiency, geriatric or severely debilitated patients, head injuries or increased intracranial pressure, & acute abdominal conditions (e.g., colic)
- ▶ Adverse Effects: Respiratory depression, histamine release, bronchoconstriction, CNS depression, GI (nausea, vomiting, & decreased intestinal peristalsis), mydriasis (dogs), salivation (esp. cats); physical dependence (chronic use). HORSES (in addition): Tachycardia with PVC's, profuse sweating, & hyperpnea
- ▶ Give very slowly if using IV (many state not to use IV), may be irritating if given SC
- ▶ C-II controlled substance

Uses/Indications

Although no product is licensed in the United States for veterinary use, this agent has been used as an analgesic in several different species. It has been used as sedative/analgesic in small animals for both post-operative pain and for medical conditions such as acute pancreatitis and thermal burns, but usually other opiates are preferred as the drug has a short analgesic duration of activity and can cause significant histamine release. It is occasionally used in equine medicine in the treatment of colic and in other large animal species for pain control.

Pharmacology/Actions

Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle.

The morphine-like agonists (morphine, meperidine, oxymorphone) have primary activity at the *mu* receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include: **CNS:** euphoria, sedation, and confusion. **Cardiovascular:** bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. **Urinary:** Increased bladder sphincter tone can induce urinary retention.

Meperidine is primarily a *Mu* agonist. It is approximately 1/8th as potent as morphine, but produces equivalent respiratory depression at equi-analgesic doses as morphine. Like morphine, it can cause histamine release. It does not have antitussive activity at doses lower than those causing analgesia. Meperidine is the only used opioid that has vagolytic and negative inotropic properties at clinically used doses. One study in ponies demonstrated changes in jejunal activity after meperidine administration, but no effects on transit time or colonic electrical activity were noted.

Refer to the monograph: *Narcotic (opiate) Analgesic Agonists, Pharmacology of*, for more information.

Pharmacokinetics

Although generally well absorbed orally, a marked first-pass effect limits the oral effectiveness of meperidine. After injection by IM or subcutaneous routes the peak analgesic effects occur between 30–60 minutes, with the IM route having a slightly faster onset. Duration of action is variable with effects generally lasting from 1–6 hours in most species. In dogs and cats, analgesic duration of only 1–2 hours is generally seen at clinically used doses. The drug is metabolized primarily in the liver (mostly hydrolysis with some conjugation) and approximately 5% is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

Meperidine is contraindicated in cases where the patient is hypersensitive to narcotic analgesics, or in patients receiving monamine oxidase inhibitors (MAOIs). It is also contraindicated in patients with diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract. All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's disease), and in geriatric or severely debilitated patients.

Many clinicians state that meperidine should not be administered intravenously. If given IV, it must be given very slowly or severe hypotension can result.

Meperidine should be used with caution in patients with head injuries or increased intracranial pressure and acute abdominal conditions (e.g., colic) as it may obscure the diagnosis or clinical course of these conditions. It should be used with extreme caution in patients suffering from respiratory disease or from acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation).

Opiate analgesics are also contraindicated in patients who have been stung by the scorpion species *Centruroides sculpturatus* Ewing and *C. gertschi* Stahnke as they may potentiate these venoms.

Adverse Effects

Meperidine may be irritating when administered subcutaneously and must be given very slowly IV or it may cause severe hypotension. It can cause pronounced histamine release, particularly with IV administration. At usual doses, the primary concern is the effect the opioids have on respiratory function. Decreased tidal volume, depressed cough reflex, and the drying of respiratory secretions may all have a detrimental effect on a susceptible patient. Bronchoconstriction following IV doses has been noted in dogs. Gastrointestinal effects may include: nausea, vomiting, and decreased intestinal peristalsis. In dogs, meperidine causes mydriasis (unlike morphine). If given orally, the drug may be irritating to the buccal mucosa and cause salivation; this is of particular concern in cats. Chronic administration can lead to physical dependence.

In horses undergoing general anesthesia, meperidine has been associated with a reaction that manifests as tachycardia with PVC's, profuse sweating, and hyperpnea.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Most opiates are excreted into milk. Meperidine enters human breast milk at concentrations slightly higher than those found in serum, but effects on nursing offspring may not be significant.

Overdosage/Acute Toxicity

In most species, overdosage may produce profound respiratory and/or CNS depression. Other effects can include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Some species (especially cats) may demonstrate CNS excitability (hyperreflexia, tremors) and seizures at doses greater than 20 mg/kg. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated, and animals should be closely observed as naloxone's effects can diminish before subtoxic levels of meperidine are attained. Mechanical respiratory support should also be considered in cases of severe respiratory depression.

Pentobarbital has been suggested as a treatment for CNS excitement and seizures in cats. Caution must be used as barbiturates and narcotics can have additive effects on respiratory depression.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving meperidine and may be of significance in veterinary patients:

- **CNS DEPRESSANTS, OTHER** (e.g., anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol, etc.): May cause increased CNS or respiratory depression when used with meperidine
- **DIURETICS**: Opiates may decrease efficacy in CHF patients
- **ISONIAZID**: Meperidine may enhance INH adverse effects
- **MONAMINE OXIDASE (MAO) INHIBITORS** (e.g., amitraz, possibly selegiline): Meperidine is contraindicated in patients receiving monamine oxidase (MAO) inhibitors for at least 14 days after receiving MAO inhibitors in humans. Some human patients have exhibited signs of opiate overdose after receiving therapeutic doses of meperidine while taking MAOIs.
- **MUSCLE RELAXANTS, SKELETAL**: Meperidine may enhance neuromuscular blockade
- **TRICYCLIC ANTIDEPRESSANTS** (clomipramine, amitriptyline, etc.): Meperidine may exacerbate the effects of tricyclic antidepressants
- **WARFARIN**: Opiates may potentiate anticoagulant activity

Laboratory Considerations

- As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

Doses

■ DOGS:

Analgesic duration in dogs usually lasts 45 minutes to 1 hour. Drug may also be given IV, but SLOWLY.

- a) Analgesic for acute pancreatitis: 5–10 mg/kg IM (Morgan 1988)
- b) 5–10 mg/kg IM, SC. Duration of effect is short (30–60 minutes) (Mama 2002b)
- c) For perioperative pain: 3–5 mg/kg IM or SC. Duration of action 1–2 hours (Pascoe 2000)
- d) Preanesthetic: 2.5–6.5 mg/kg (Booth 1988a)

■ CATS:

For perioperative pain:

- a) 3–5 mg/kg IM or SC. Duration of action 1–2 hours (Pascoe 2000)
- b) 2–5 mg/kg IM, SC. Duration of effect is short (30 minutes to an hour) (Mama 2002b)

As a preanesthetic:

- a) 2.2–4.4 mg/kg (Booth 1988a)

Not recommended for cats. (Scherk 2003a)

■ FERRETS:

- a) 5–10 mg/kg SC or IM every 2–3 hours (Williams 2000)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: For moderate pain: 5–10 mg/kg SC, IM q2–3h. Using Banana flavored oral syrup: 0.2 mg/mL in drinking water (Ivey and Morrissey 2000)
- a) Analgesic (patient administered moderate pain relief): 0.2 mg/mL in drinking water (Huerkamp 1995)

■ CATTLE:

As an analgesic:

- a) 3.3–4.4 mg/kg SC or IM (Jenkins 1987)
- b) 500 mg IM (Booth 1988a)
- c) 150–200 mg/100 lbs IM or SC (or slow IV) (McConnell and Hughey 1987)

■ HORSES:

Note: Narcotics (meperidine included) may cause CNS excitement in the horse. Some recommend pretreatment with acepromazine.

mazine (0.02–0.04 mg/kg IV), or xylazine (0.3–0.5 mg/kg IV) to reduce the behavioral changes caused by these drugs. **WARNING:** Narcotic analgesics can mask the behavioral and cardiovascular signs associated with mild colic.

As an analgesic:

- 2.2–4 mg/kg IM or 0.2–0.4 mg/kg IV (may cause excitement) (Robinson 1987)
- 2–4 mg/kg IM or IV (may cause excitement and hypotension with IV use) (Jenkins 1987)
- 500 mg (total dose) IV (slowly, CNS excitement may occur) or 1000 mg (total dose) IM (Booth 1988a)
- 0.2–0.4 mg/kg IV (Muir 1987)

■ SWINE:

As a restraining agent:

- Given alone the drug does not give much restraint in large animals. Has been used in combination with promazine (2 mg/kg IM) and atropine (0.07–0.09 mg/kg IM) at a dose of 1–2 mg/kg IM as a preanesthetic 45–60 minutes before barbiturate/inhalant anesthesia. All the above should be given in separate sites (Booth 1988a)

As an analgesic:

- 2 mg/kg IM q4h IM as needed (Jenkins 1987)

■ SHEEP & GOATS:

As an analgesic:

- Up to 200 mg total dose IM (Jenkins 1987)

Monitoring

- Respiratory rate/depth
- CNS level of depression/excitation
- Blood pressure (especially with IV use)
- Analgesic activity

Client Information

- Oral dosage forms may cause mouth irritation.
- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision.

Chemistry/Synonyms

A synthetic opiate analgesic, meperidine HCl is a fine, white, crystalline, odorless powder that is very soluble in water, sparingly soluble in ether and soluble in alcohol. It has a pK_a of 7.7–8.15 and a melting range of 186–189°C. The pH of the commercially available injectable preparation is between 3.5 and 6.

Meperidine HCl may also be known as: pethidine HCl, isonipicaine, meperidine hydrochloride, pethidini hydrochloridum; *Alodan*®, *Centralgine*®, *Demerol*®, *Dolantin*®, *Dolantina*®, *Dolantine*®, *Dolestine*®, or *Dolosal*®.

Storage/Stability/Compatibility

Meperidine is stable at room temperature. Avoid freezing the injectable solution and protect from light during storage. Meperidine has not exhibited significant adsorption to PVC IV bags or tubing in studies to date.

Meperidine is reported to be physically **compatible** with the following fluids and drugs: sodium chloride 0.45 and 0.9%, Ringer's injection, lactated Ringer's injection, dextrose 2.5, 5 and 10% for injection, dextrose/saline combinations, dextrose/Ringers lactated solutions, atropine, benzquinamide, butorphanol, chlorpromazine, dimenhydrinate, diphenhydramine HCl, dobutamine, droperidol, fentanyl citrate, glycopyrrolate, metoclopramide, pentazocine lactate, promazine HCl, succinylcholine, and verapamil HCl.

Meperidine is reported to be physically **incompatible** when mixed with the following agents: aminophylline, amobarbital sodium,

heparin sodium, hydrocortisone sodium succinate, methicillin, methylprednisolone sodium succinate, morphine sulfate, nitrofurantoin sodium, oxytetracycline HCl, pentobarbital sodium, phenobarbital sodium, phenytoin sodium, sodium iodide, tetracycline HCl, thiopental sodium, and thiamylal sodium.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Meperidine HCl Injection: 25 mg/mL in 1 mL vials, amps & 1 mL *Carpject* syringes; 50 mg/mL in 1 mL vials, 0.5 mL, 1 mL, 1.5 mL and 2 mL amps, 30 mL multi-dose vials and 1 mL *Carpject* syringes; 75 mg/mL in 1 mL vials & 1 mL *Carpject* syringes; 100 mg/mL in 1 mL amps, 20 mL multidose vials and 1 mL *Carpject* syringes; *Demerol*® (Abbott); generic, (Rx, C-II)

Meperidine HCl Tablets: 50 mg & 100 mg tablets; generic; (Rx, C-II)

Meperidine HCl Syrup/Oral Solution: 50 mg/5 mL in 473 mL & 500 mL, *Demerol*® (Sanofi-Synthelabo); generic (Roxane); (Rx, C-II)

Note: Meperidine is listed as a Class-II controlled substance and all products require a prescription. Very accurate record keeping is required as to use and disposition of stock.

MERCAPTOPURINE

(mer-kap-toe-pyoor-een) Purinethol®

ANTINEOPLASTIC; IMMUNOSUPPRESSANT

Prescriber Highlights

- Oral antineoplastic/immunosuppressant used for adjunctive treatment of lymphosarcoma, acute leukemias, & severe rheumatoid arthritis or other autoimmune conditions (e.g., unresponsive ulcerative colitis)
- Contraindications: Hypersensitivity to it
- Caution (risk versus benefit): In patients with hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage), or with a history of urate urinary stones
- Adverse Effects: GI effects (nausea, anorexia, vomiting, diarrhea) most likely; bone marrow suppression, hepatotoxicity, pancreatitis, GI (including oral) ulceration & potentially, dermatologic reactions.
- Teratogenic; use milk replacer in nursing animals
- Drug interactions

Uses/Indications

Veterinary uses of mercaptopurine include adjunctive therapy of lymphosarcoma, acute leukemias, and severe rheumatoid arthritis. It may have potential benefit in treating other autoimmune conditions (e.g., unresponsive ulcerative colitis) as well.

Pharmacology/Actions

Intracellularly, mercaptopurine is converted into a ribonucleotide that acts as a purine antagonist, thereby inhibiting RNA and DNA synthesis. Mercaptopurine acts as an immunosuppressant, primarily inhibiting humoral immunity.

Pharmacokinetics

Absorption after oral dosing is variable and incomplete. Absorbed drug and its metabolites are distributed throughout the total body water. The drug crosses the blood-brain barrier, but not in levels significant enough to treat CNS neoplasms. It is unknown whether mercaptopurine enters milk.

Via the enzyme, xanthine oxidase, mercaptopurine is rapidly metabolized in the liver to 6-thiouric acid, which along with the parent compound and other metabolites are principally excreted in the urine.

Contraindications/Precautions/Warnings

Mercaptopurine is contraindicated in patients hypersensitive to it. The drug should be used cautiously (risk versus benefit) in patients with hepatic dysfunction, bone marrow depression, infection, renal function impairment (adjust dosage), or a history of urate urinary stones.

Adverse Effects

At usual doses, GI effects (nausea, anorexia, vomiting, diarrhea) are most likely seen in small animals. However, bone marrow suppression, hepatotoxicity, pancreatitis, GI (including oral) ulceration, and dermatologic reactions are, potentially, possible.

Reproductive/Nursing Safety

Mercaptopurine is mutagenic and teratogenic and is not recommended for use during pregnancy. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

It is not known whether mercaptopurine is excreted in milk, but use of milk replacer is recommended for nursing bitches or queens.

Overdosage/Acute Toxicity

Toxicity may present acutely (GI effects) or be delayed (bone marrow depression, hepatotoxicity, gastroenteritis). It is suggested to use standard protocols to empty the GI tract if ingestion was recent and to treat supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mercaptopurine and may be of significance in veterinary patients:

- **ALLOPURINOL:** The hepatic metabolism of mercaptopurine may be decreased by concomitant administration of allopurinol. In humans, it is recommended to reduce the mercaptopurine dose to $\frac{1}{4}$ – $\frac{1}{2}$ usual if both drugs are to be used together.
- **AMINOSALICYLATES (mesalamine, sulfasalazine):** May increase risk for mercaptopurine toxicity
- **HEPATOTOXIC DRUGS** (e.g., halothane, ketoconazole, valproic acid, phenobarbital, primidone, etc.): Mercaptopurine should be used cautiously with other drugs that can cause hepatotoxicity. In humans, one study demonstrated increased hepatotoxicity when mercaptopurine was used in conjunction with doxorubicin.
- **IMMUNOSUPPRESSIVE DRUGS** (e.g., azathioprine, cyclophosphamide, corticosteroids): Use with other immunosuppressant drugs may increase the risk of infection.
- **MYELOSUPPRESSIVE DRUGS** (e.g., antineoplastics, chloramphenicol, flucytosine, amphotericin B, colchicine, etc.): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs; bone marrow depression may be additive. In humans, enhanced bone marrow depression has occurred when used concomitantly with trimethoprim/sulfa.

- **VACCINES, LIVE:** Live virus vaccines should be used with caution, if at all, during therapy
- **WARFARIN:** Mercaptopurine may reduce anticoagulant effect

Laboratory Considerations

- Mercaptopurine may give falsely elevated **serum glucose** and **uric acid** values when using a SMA (sequential multiple analyzer) 12/60.

Doses

■ DOGS:

- a) As an immunosuppressant in combination with corticosteroids for treating bullous pemphigoid: 2.2 mg/kg once daily (q24h), then q48h. (Swartout 2004)
- b) For erosive, immune-mediated polyarthritis in combination with corticosteroids: 2 mg/kg PO once daily (q24h) for 14–21 days, then q48h (every other day). (Beale and Worley 2004)
- c) For treatment of immune-mediated diseases or acute lymphocytic and granulocytic leukemias: 50 mg/m² PO once daily (q24h) to effect, then every other day (q48h) or as needed. (Jacobs, Lumsden et al. 1992)

Monitoring

- Hemograms (including platelets) should be monitored closely; initially every 1–2 weeks and every 1–2 months once on maintenance therapy. It is recommended by some clinicians that if the WBC count drops to between 5,000–7,000 cells/mm³ the dose be reduced by 25%. If WBC count drops below 5,000 cells/mm³ treatment should be discontinued until leukopenia resolves
- Liver function tests; serum amylase, if indicated
- Efficacy

Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related neoplasms or mortality.
- Clients should contact veterinarian should the animal exhibit signs of abnormal bleeding, bruising, anorexia, vomiting, or infection.
- Although, no special precautions are necessary with handling intact tablets, it is recommended to wash hands after administering the drug.

Chemistry/Synonyms

A purine analog, mercaptopurine occurs as a slightly yellow, crystalline powder. It is insoluble in water and has a pKa of 7.6.

Mercaptopurine may also be known as: 6-mercaptopurine, 6-MP, 6MP, mercaptopurinum, NSC-755, purinethiol, WR-2785, *Flocofil*®, *Ismipur*®, *Mercap*®, *Mercaptina*®, *Puri-Nethol*®, *Purinethol*®, and *Varimer*®.

Storage/Stability

Mercaptopurine tablets should be stored at room temperature in well-closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Mercaptopurine Tablets: 50 mg; *Purinethol*® (Gate Pharmaceuticals); generic (Par); (Rx)

MEROPENEM

(mare-oh-pen-ehm) Merrem I.V.®

CARBAPENEM ANTIBIOTIC

Prescriber Highlights

- ▶ Carbapenem antibiotic similar to imipenem, but does not cause seizures & may be more effective against some resistant gram-negative infections
- ▶ Use should be reserved for documented resistant infections &/or when aminoglycosides not indicated (renal dysfunction, CNS infections)
- ▶ Seems well-tolerated in animal patients
- ▶ Must be given IV or SC
- ▶ Expense an issue

Uses/Indications

Meropenem may be useful in treating resistant gram-negative bacterial infections, particularly when aminoglycoside use would be risky (*i.e.*, renal failure) or not effective (*i.e.*, resistance or CNS infections). While meropenem has a very broad spectrum, less expensive or easier to administer antibiotics are usually effective for other infections.

Pharmacology/Actions

Meropenem has a broad antibacterial spectrum similar to that of imipenem, but meropenem is more active against Enterobacteriaceae and less so against gram-positive bacteria. Oxacillin-resistant Staphylococcus are usually resistant to meropenem. Because meropenem is more stable to renal dehydropeptidase-I than is imipenem, it does not require the addition of cilastatin to inhibit that enzyme. Meropenem may also have less potential to induce seizures than imipenem.

Pharmacokinetics

Meropenem must be administered via parenteral means. After SC injection in dogs, bioavailability is 84%. After IV injection in dogs, meropenem's volume of distribution is approximately 0.37 L/kg and protein binding about 12%; half-life \approx 40 minutes, and clearance \approx 6.5 mL/min/kg. Concentrations of unbound drug in tissue fluid and plasma are similar.

In ewes, after IM injection meropenem was rapidly absorbed and had a bioavailability equal to that of intravenous dosing. Volume of distribution at steady state was 0.06 L/kg and protein binding about 43%; elimination half-life was about 43 minutes. 91% of the drug was recovered in the urine over 24 hours after IM injection.

Pharmacokinetic data for humans include: wide distribution in body tissues and fluids, including into the CSF and bile; very low protein binding \approx 2%; in patients with normal renal function, elimination half-life is about an hour. One inactive metabolite has been identified, but the majority of the drug is eliminated via renal mechanisms (tubular secretions and glomerular filtration) and 70% of a dose is recovered unchanged in the urine over 12 hours.

Contraindications/Precautions/Warnings

Meropenem is contraindicated in patients hypersensitive to it or other carbapenems, and those that have developed anaphylaxis after receiving any beta-lactam antibiotic.

Adverse Effects

Meropenem is usually very well tolerated. Animals given the drug SC may show slight hair loss over injection sites. In human patients receiving meropenem, only GI effects (nausea, vomiting, diarrhea) have been reported to occur in greater than 1% of patients treated.

Reproductive/Nursing Safety

In humans, meropenem is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Meropenem is likely safe to use during lactation.

Overdosage/Acute Toxicity

Overdoses of meropenem are unlikely to occur in patients with normal renal function. In human trials, doses of 2 grams every 8 hours failed to demonstrate any significant adversity. Should an overdose occur, the drug can be discontinued if necessary or the next dose could be delayed by a few hours. Meropenem can be removed via hemodialysis when necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving meropenem and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** *In vitro* evidence of synergy against *Pseudomonas aeruginosa*
- **PROBENECID:** May increase serum concentrations and elimination half-life of meropenem

Laboratory Considerations

No specific laboratory interactions were noted for meropenem.

Doses

■ DOGS & CATS:

For treatment of susceptible infections:

- a) For bacteremia/sepsis: 24 mg/kg IV q24h (once daily) or 12 mg/kg SC q8h;

For UTI: 12 mg/kg SC q12h;

For CNS infections: 40 mg/kg IV or SC q8h. This dose is extrapolated from children and maximum dose per administration is 2 grams. To help prevent development of resistant strains that might infect humans, use should be limited or avoided unless ultimately necessary. (Greene, Hartmann et al. 2006)

- b) For systemic infections: 12 mg/kg q8h SC or 24 mg/kg IV q24h (once daily); for urinary tract infections 12 mg/kg q12h SC (Papich 2002a)
- c) 125 mg (total dose) for small dogs and cats q8h IV or SC; 250 mg q8h IV or SC for medium dogs; 500 mg q8h IV or SC for large (>100 lbs.) dogs. **Note:** If serum creatinine greater than 4, may be given q12h. (Aucoin 2002b)

Plumb's Note: The recommended dose for treating meningitis with meropenem in humans is 40 mg/kg IV q8h. Until more information becomes available for veterinary patients, consider using a similar dose if treating dogs or cats (with normal renal function) for CNS bacterial infections.

Monitoring

- There are no specific monitoring requirements for meropenem except to monitor for clinical efficacy.

Client Information

- This drug is generally used on an inpatient basis usually because of the seriousness of the infections treated, but clients could give SC injections at home, particularly when treating urinary tract infections.

Chemistry/Synonyms

A synthetic carbapenem antibiotic, meropenem occurs as a clear to white to pale yellow powder or crystals. It is very slightly soluble in water or hydrated alcohol and practically insoluble in acetone or ether. When the commercially available injection is reconstituted the resulting pH is between 7.3 and 8.3.

Meropenem may also be known as: ICI-194660, SM-7338, *Meropen*®, *Meropen*®, *Merrem*®, *Optinem*®, or *Zeropenem*®.

Storage/Stability/Compatibility

The powder for injection should be stored at controlled room temperature (20–25°C; 69–77°F). When the commercially available powder for injection is reconstituted with sterile water for injection (up to a concentration of 50 mg/mL), it is stable (per the manufacturer) for up to 2 hours at room temperature; up to 12 hours when refrigerated. The package insert lists several options for dilution with several different solutions in plastic IV bags, syringes, minibags, etc. The longest time the drug the manufacturer states the drug is stable, is 48 hours when diluted in normal saline or sterile water for injection at concentrations from 1–20 mg/mL in plastic syringes and kept refrigerated.

For subcutaneous administration in veterinary patients, meropenem has been diluted to a concentration of 20 mg/mL in sterile sodium chloride 0.9%. The solution should be protected from light and is reportedly stable if kept refrigerated for up to 96 hours. Once the refrigerated solution is brought back to room temperature it should be used within 6 hours. (Jordan 2004)

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Meropenem Powder for Injection: 500 mg and 1 g in 20 mL, & 30 mL vials; *Merrem*® I.V. (AstraZeneca); (Rx)

METFORMIN HCL

(met-fore-min) Glucophage®

ANTIHYPERGLYCEMIC

Prescriber Highlights

- Oral anti-hyperglycemic agent that potentially could be useful in the adjunctive treatment of non-insulin dependent diabetes mellitus (NIDDM) in cats; use is controversial
- Limited experience, but efficacy has been disappointing
- Contraindicated in patients hypersensitive to it; with renal dysfunction, metabolic acidosis, or temporarily when iodinated contrast agents are to be used (see Drug Interactions)
- Adverse effects may include lethargy, inappetence, vomiting, & weight loss
- Potentially significant drug interactions
- Human dosage forms may be difficult to accurately dose in cats

Uses/Indications

Metformin may be useful in the adjunctive treatment of non-insulin dependent diabetes mellitus in cats. Only limited trials of the drug have been performed in cats, with only very limited success when the drug is used alone. Studies comparing its safety and efficacy with other oral antihyperglycemics (e.g., glipizide or insulin) were not located.

Pharmacology/Actions

Metformin's actions are multifaceted. At usual dosages, it increases insulin's ability to transport glucose across cell membranes in skeletal muscle without increasing lactate production and inhibits formation of advanced glycosylation end-products. Metformin decreases hepatic glucose production, and may decrease intestinal absorption of glucose. It does not stimulate insulin production or release from the pancreas and, therefore, does not cause hypoglycemia.

Pharmacokinetics

A pharmacokinetic study done in cats (Chastain, Panciera et al. 1999) showed that metformin is variably absorbed after oral administration 35–67%. In cats, steady-state volume of distribution was 0.55 L/kg; elimination half-life about 12 hours and total clearance was 0.15 L/hr/kg. Metformin is primarily eliminated via the kidneys. The authors concluded that the drug's pharmacokinetics are similar to that seen in humans, and that a dosage of 2 mg/kg twice daily would give plasma concentrations known to be effective in humans.

Contraindications/Precautions/Warnings

In humans (and presumably cats), metformin is contraindicated in patients hypersensitive to it, with renal dysfunction or metabolic acidosis. It is also temporarily contraindicated when iodinated contrast agents are to be used (see Drug Interactions).

Adverse Effects

In cats, metformin may cause lethargy, inappetence, vomiting, and weight loss. In a study evaluating metformin in diabetic cats (Nelson, Spann et al. 2004), 1 of 5 diabetic cats studied died 11 days after receiving metformin. As the cause of death was undetermined, metformin could not be ruled out as a causative factor. Hypoglycemia would not be an expected adverse effect when metformin is used as a single agent.

Reproductive/Nursing Safety

In pregnant humans, metformin is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Metformin is excreted in maternal milk in levels equivalent to those found in plasma. While adverse effects in nursing kittens would be unlikely, use with caution in lactating queens.

Overdosage/Acute Toxicity

There is limited information available. Massive overdoses in humans (100 grams) caused hypoglycemia only 10% of the time, but lactic acidosis occurred.

There were 26 exposures to metformin reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 24 were dogs with 5 showing clinical signs and the remaining 2 cases were 1 bird and 1 cat neither of which showed clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting and depression.

Treatment is symptomatic and supportive. Hemodialysis can enhance the removal of drug from the body.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving metformin and may be of significance in veterinary patients:

- **ACE INHIBITORS:** May increase risk for hypoglycemia
- **CIMETIDINE:** In humans, cimetidine can cause a 60% increase in peak metformin plasma levels and a 40% increase in AUC
- **CORTICOSTEROIDS:** May reduce efficacy
- **DIURETICS, THIAZIDE:** May reduce hypoglycemic efficacy
- **FUROSEMIDE:** Can increase the AUC and plasma levels of metformin by 22% in humans; metformin can decrease the peak plasma concentrations and AUC of furosemide
- **IODINATED CONTRAST AGENTS, PARENTERAL:** May cause acute renal failure and lactic acidosis if used within 48 hours of a metformin dose
- **ISONIAZID:** May reduce hypoglycemic efficacy
- **SYMPATHOMIMETIC AGENTS:** May reduce hypoglycemic efficacy

Laboratory Considerations

No specific laboratory interactions or considerations noted.

Doses

- **CATS:**
 - a) For cats with non-insulin dependent diabetes mellitus: 5 mg/kg PO twice daily. (Greco 2002a) **Note:** In a more recent reference the author states that “*metformin has been shown toxic to cats and should not be used. It is also ineffective.*” (Greco 2007c)
 - b) For cats with non-insulin dependent diabetes mellitus (patients with detectable concentrations of insulin): 50 mg (total dose) per cat PO twice daily; may be efficacious only

in cats with detectable concentrations of insulin at time of treatment (Nelson, Spann et al. 2004)

- c) For early NIDDM: 2 mg/kg PO q12h (Melendez and Lorenz 2002)

Monitoring

- **Efficacy:** Standard methods of monitoring efficacy for diabetes treatment should be followed (e.g., fasting blood glucose, appetite, attitude, body condition, PU/PD resolution, and perhaps serum fructosamine and/or glycosylated hemoglobin levels)
- **Renal function** (baseline and annually)
- **Adverse effects**

Client Information

- Clients should understand the relative “investigational” nature of using this compound in cats and report any untoward effects to the veterinarian.

Chemistry/Synonyms

A biguanide oral anti-hyperglycemic agent, metformin HCl occurs as white to off-white crystals that are slightly soluble in alcohol and freely soluble in water. It is a weak base; a 1% aqueous solution of metformin HCl has a pKa of 6.68 and metformin base has a pKa of 12.4.

Metformin HCl may also be known as dimethylbiguanide HCl or metformini hydrochloridum. There are many proprietary names outside of the USA for this drug.

Storage/Stability

Metformin HCl oral products (oral tablets, sustained-release tablets, and fixed dose combination products with glipizide or rosiglitazone) should be stored protected from light at a controlled room temperature of 20–25°C (68–77°F), excursions permitted to 15–30°C (59–86°F). The combination product containing metformin HCl and glyburide should be stored at temperatures up to 25°C (77°F) and protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Metformin HCl Tablets: 500 mg, 850 mg, 1000 mg; *Glucophage*® (Bristol-Myers Squibb); generic; (Rx)

Metformin HCl Extended-Release Tablets: 500 mg, 750 mg & 1000 mg; *Glucophage XR*® (Bristol-Myers Squibb); *Glumetza*® (Depomed); *Fortamet*® (First Horizon); (Rx)

Metformin HCl Oral Solution: 500 mg/5 mL in 120 mL & 480 mL; *Riomet*® (Ranbaxy); (Rx)

The following fixed-dose oral tablet combination products are available:

Glyburide/Metformin Hydrochloride Film-coated Tablets: 1.25 mg/250 mg, 2.5 mg/500 mg, 5 mg/500 mg; *Glucovance*® (Bristol-Myers Squibb); generic; (PAR); (Rx)

Rosiglitazone Maleate/Metformin HCl Film-coated Tablets: 2 mg/500 mg, 2 mg/1000 mg, 4 mg/500 mg or 4 mg/1000 mg; *Avandamet*® (GlaxoSmithKline); (Rx)

Glipizide/Metformin HCL Film-coated Tablets: 2.5 mg/250 mg, 2.5 mg/500 mg and 5 mg/500 mg; *Metaglip*® (Bristol-Myers Squibb); generic; (Rx)

Pioglitazone HCl and Metformin HCl Film-coated Tablets: 15 mg/500 mg, 15 mg/850 mg; *ActoPlus Met*® (Takeda); (Rx)

METHADONE HCL

(meth-a-done) Dolophine®

OPIATE AGONIST

Prescriber Highlights

- ▶ Narcotic agonist that may be used as an alternative to morphine in dogs, cats
- ▶ Causes less histamine-release (with IV), sedation & vomiting than morphine
- ▶ Depending on country, may be significantly more expensive than morphine
- ▶ C-II controlled substance in USA

Uses/Indications

Methadone may be used as an alternative opioid preanesthetic or analgesic in dogs or cats. It is also being investigated for epidural use for horses.

Pharmacology/Actions

In small animals methadone acts similarly to morphine with regard to its degree of analgesia and duration of action. Methadone is a *mu*-receptor agonist that also is a non-competitive inhibitor of NMDA (n-methyl-d-aspartate) receptors. Methadone is more lipid-soluble than is morphine and approximately 1–1.5 times as potent. It does not cause significant histamine release when administered intravenously.

Refer to the monograph: *Narcotic (opiate) Analgesic Agonists, Pharmacology of*, for more information.

Pharmacokinetics

Limited information is available on the pharmacokinetics of methadone in domestic animals. One study in dogs showed a terminal elimination half-life of 2–3 hours. In humans, methadone is well absorbed from the GI tract (PO), and after subcutaneous or intramuscular injection. It is widely distributed and extensively bound to plasma proteins (60–90%). Methadone is metabolized in the liver primarily by the cytochrome P450 CYP3A isoenzyme, but other isoenzymes also play a role. Metabolites do not have activity. Methadone half-life is widely variable in humans (15–60 hours); elimination half-lives may be extended if giving multiple doses.

Contraindications/Precautions/Warnings

All opiates should be used with caution in patients with head injuries, elevated CSF pressures, and in geriatric or severely debilitated patients.

Adverse Effects

Adverse effects from methadone can include sedation, vomiting, defecation, constipation, bradycardia, and respiratory depression. Methadone tends to cause less sedation or vomiting than morphine.

Reproductive/Nursing Safety

Methadone is relatively safe to use at low dosages for short periods during the first two trimesters of pregnancy, but it should be avoided late in term as significant respiratory depression and increased rates of stillbirths have been noted in humans. Infants of humans who have been taking methadone for opiate addiction, have shown high rates of moderate to severe opiate withdrawal signs during the neonatal period, and long-term developmental problems.

Although methadone enters maternal milk, the American Academy of Pediatrics considers methadone compatible with breast-feeding in women.

Overdosage/Acute Toxicity

Overdosage may produce profound respiratory and/or CNS depression in most species. Newborns may be more susceptible to these effects than adult animals. Other toxic effects can include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated. Animals should be closely observed since naloxone's effects might diminish before sub-toxic levels of methadone are attained. Mechanical respiratory support should be considered in cases of severe respiratory depression. Dialysis, charcoal hemoperfusion, or forced diuresis do not appear to be beneficial in treating methadone overdoses.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methadone and may be of significance in veterinary patients:

- **ANTIARRHYTHMICS, CLASS I & III** (e.g., **lidocaine**, **procainamide**, **quinidine**, **amiodarone**): Use with methadone may increase risks for arrhythmias
- **AZOLE ANTIFUNGALS** (**fluconazole**, **itraconazole**, **ketoconazole**): May increase methadone levels
- **CALCIUM CHANNEL BLOCKERS**: Use with methadone may increase risks for arrhythmias
- **CNS DEPRESSANTS, OTHER** (e.g., **anesthetic agents**, **antihistamines**, **phenothiazines**, **barbiturates**, **tranquillizers**, **alcohol**, etc.): May cause increased CNS or respiratory depression when used with methadone
- **CORTICOSTEROIDS (MINERALOCORTICOIDS)**: Use with methadone may increase potential for electrolyte abnormalities
- **DIURETICS**: Opiates may decrease efficacy in CHF patients
- **MACROLIDE ANTIBIOTICS** (**erythromycin**, **clarithromycin**): May inhibit metabolism of methadone and increase levels
- **MONAMINE OXIDASE (MAO) INHIBITORS** (e.g., **amitraz**, possibly **selegiline**): Meperidine with MAOIs in humans has caused severe CNS/behavior reactions and potentially could do the same with methadone; avoid concomitant use
- **MUSCLE RELAXANTS, SKELETAL**: Methadone may enhance neuromuscular blockade
- **PHENOBARBITAL, PHENYTOIN**: May decrease methadone levels
- **RIFAMPIN**: May decrease methadone levels
- **SSRI ANTIDEPRESSANTS** (**fluoxetine**, **sertraline**, etc.): May increase methadone levels
- **St JOHN'S WORT**: May decrease methadone levels
- **TRICYCLIC ANTIDEPRESSANTS** (**clomipramine**, **amitriptyline**, etc.): Methadone may exacerbate the effects of tricyclic antidepressants
- **WARFARIN**: Opiates may potentiate anticoagulant activity
- **ZIDOVUDINE**: Methadone may increase zidovudine levels

Laboratory Considerations

- As they may increase biliary tract pressure, opiates can increase plasma **amylase** and **lipase** values up to 24 hours following their administration.

Doses

■ DOGS:

- As a pre-anesthetic: 0.2–0.5 mg/kg SC, IM; or a combination of methadone 0.1–0.3 mg/kg with acepromazine 0.02–0.05 mg/kg SC, IM (Cornell 2004)
- For pain: 0.1–0.25 mg/kg IM, SC, IV. Duration of effect 4–6 hours. (Otero 2006a)
- For perioperative pain control: 0.1–0.5 mg/kg IM or SQ; duration of effect is 2–4 hours. (Pascoe 2006)

■ CATS:

- For perioperative pain control: 0.05–0.5 mg/kg IV, IM or SC q4–6h (Tranquilli 2003)
- As a pre-anesthetic: 0.1–0.2 mg/kg SC, IM; or a combination of methadone 0.1–0.3 mg/kg with acepromazine 0.02–0.05 mg/kg SC, IM (Cornell 2004)
- For moderate to severe pain: 0.1–0.2+ mg/kg IM or SQ; duration of effect is 2–6 hours. For IV dosing use ½ the low end dose, titrate over 3–5 minutes; duration of effect is 1–4 hours. (Mathews 2006)
- For pain: 0.1–0.2 mg/kg SC, IV. Duration of effect 2–3 hours. (Otero 2006a)

Monitoring

- Analgesic or preanesthetic efficacy
- At higher dosages, monitor for respiratory depression

Client Information

- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision.
- If being used orally for pain control, be sure to keep out of reach of children and pets.

Chemistry/Synonyms

A synthetic diphenylheptane-derivative narcotic agonist, methadone HCl occurs as an odorless, colorless or white crystalline powder. It is freely soluble in water, chloroform, or alcohol and practically insoluble in ether or glycerol. The pH of a 1% solution in water is between 4.5 and 6.5. The commercially available injection has a pH from 3–6.5. The dispersible tablet formulation (*Diskets*®) contains insoluble ingredients that deter their use for injection.

Methadone may also be known as: Amidine HCl, amidone HCl, methadoni hydrochloridum, Phenadone, *Adolan*®, *Biodone*®, *Cloro Nona*®, *Dolmed*®, *Eptadone*®, *Gobbidona*®, *Heptadon*®, *Ketalgine*®, *Metadol*®, *Metasedin*®, *Methaddict*®, *Methadose*®, *Methatabs*®, *Methex*®, *Pallidone*®, *Phymet*®, *Physeptone*®, *Pinadone*®, *Sedo*®, *Symoron*®, or *Synastone*®.

Storage/Stability/Compatibility

Unless otherwise labeled, methadone products should be stored at room temperature and protected from light.

Methadone injection is reportedly stable when mixed in a syringe with acepromazine. The injection is reportedly **not compatible** with pentobarbital, phenobarbital, amobarbital, or thiopental.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Methadone HCl Injection: 10 mg/mL in 20 mL multidose vials; Methadone Hydrochloride (aaiPharma); (Rx, C-II)

Methadone HCl Tablets: 5 mg & 10 mg; Dispersible Tablets 40 mg; *Dolophine*® Hydrochloride (Roxane); *Methadose*® (Mallinckrodt); generic; (Rx, C-II)

Methadone HCl Oral Solution/Concentrate: 1 mg/mL, & 10 mg/mL (also in sugar & dye free) in 30 mL, 500 mL, 946 mL & 1 L; Methadone Hydrochloride (Roxane); *Methadose*® (Mallinckrodt); (Rx, C-II)

All methadone-containing products are C-II controlled substances in the USA. When used as an analgesic, methadone may be dispensed by any pharmacy or practitioner registered with the DEA for Class-II narcotics. When methadone is used to treat narcotic addiction, specialized approval must be obtained from the FDA and, usually, state regulators.

METHAZOLAMIDE

(meth-a-zoe-la-mide) Neptazane®

CARBONIC ANHYDRASE INHIBITOR

Prescriber Highlights

- Oral carbonic anhydrase inhibitor used primarily for open angle glaucoma
- Contraindicated in patients with significant hepatic, renal, pulmonary or adrenocortical insufficiency, hyponatremia, hypokalemia, hyperchloremic acidosis or electrolyte imbalance
- Give oral doses with food if GI upset occurs
- Monitor with tonometry for glaucoma; check electrolytes

Uses/Indications

Orally administered methazolamide is used for the medical treatment of glaucoma.

Pharmacology/Actions

The carbonic anhydrase inhibitors act by a noncompetitive, reversible inhibition of the enzyme carbonic anhydrase. This reduces the formation of hydrogen and bicarbonate ions from carbon dioxide and reduces the availability of these ions for active transport into body secretions.

Pharmacologic effects of the carbonic anhydrase inhibitors include decreased formation of aqueous humor, thereby reducing intraocular pressure; increased renal tubular secretion of sodium and potassium and, to a greater extent, bicarbonate, leading to increased urine alkalinity and volume; anticonvulsant activity, which is independent of its diuretic effects (mechanism not fully understood, but may be due to carbonic anhydrase or a metabolic acidosis effect).

Pharmacokinetics

Little information is available. Methazolamide is absorbed from the GI tract albeit more slowly than acetazolamide. It is distributed throughout the body, including the CSF and aqueous humor. Methazolamide is at least partially metabolized in the liver.

Contraindications/Precautions/Warnings

Carbonic anhydrase inhibitors are contraindicated in patients with significant hepatic disease (may precipitate hepatic coma), renal or adrenocortical insufficiency, hyponatremia, hypokalemia, hyperchloremic acidosis or electrolyte imbalance. They should not be used in patients with severe pulmonary obstruction unable to increase alveolar ventilation or those who are hypersensitive to them.

Long-term use of carbonic anhydrase inhibitors is contraindicated in patients with chronic, noncongestive, angle-closure glaucoma as angle closure may occur and the drug may mask the condition by lowering intra-ocular pressures.

Adverse Effects

Potential adverse effects that may be encountered include GI disturbances (vomiting, diarrhea, inappetence), metabolic acidosis, CNS effects (sedation, depression, excitement, etc.), hematologic effects (bone marrow depression, thrombocytopenia), renal effects (crystalluria, dysuria, renal colic, polyuria, polydipsia), hypokalemia, hyperglycemia, hyponatremia, hyperuricemia, hepatic insufficiency, dermatologic effects (rash, etc.), and hypersensitivity reactions.

Combining methazolamide (oral dosing) with topical (ophthalmic) dorzolamide does not apparently yield additive reductions in intraocular pressure and may cause increased adverse effects.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Safety for use during nursing has not been established. But a related compound, acetazolamide, is excreted in the milk in concentrations unlikely to have pharmacologic effect.

Overdosage/Acute Toxicity

Information regarding overdosage of this drug is not readily available. It is suggested to monitor serum electrolytes, blood gases, volume status, and CNS status during an acute overdose. Treat symptomatically and supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methazolamide and may be of significance in veterinary patients:

- **ANTIDEPRESSANTS, TRICYCLIC:** Alkaline urine caused by methazolamide may decrease excretion
- **ASPIRIN** (or other **salicylates**): Increased risk of methazolamide accumulation and toxicity; increased risk for metabolic acidosis; methazolamide increases salicylate excretion
- **DIGOXIN:** As methazolamide may cause hypokalemia, increased risk for toxicity
- **INSULIN:** Rarely, carbonic anhydrase inhibitors interfere with the hypoglycemic effects of insulin
- **METHENAMINE COMPOUNDS:** Methazolamide may negate effects in the urine
- **POTASSIUM, DRUGS AFFECTING (corticosteroids, amphotericin B, corticotropin, or other diuretics):** Concomitant use may exacerbate potassium depletion
- **PHENOBARBITAL:** Increased urinary excretion, may reduce phenobarbital levels
- **PRIMIDONE:** Decreased primidone concentrations
- **QUINIDINE:** Alkaline urine caused by methazolamide may decrease excretion

Laboratory Considerations

- By alkalinizing the urine, carbonic anhydrase inhibitors may cause false positive results in determining **urine protein** using bromphenol blue reagent (*Albustix*®, *Albutest*®, *Labstix*®), sulfosalicylic acid (*Bumintest*®, *Exton's*® *Test Reagent*), nitric acid ring test, or heat and acetic acid test methods.
- Carbonic anhydrase inhibitors may **decrease iodine uptake** by the thyroid gland in hyperthyroid or euthyroid patients.

Doses

■ DOGS:

For medical treatment of glaucoma:

- a) 2–5 mg/kg PO q8–12h (Wilkie 2003)
- b) 2–4 mg/kg PO two to three times a day (Diehl 2007a)
- c) 3–5 mg/kg divided q12h PO (Millichamp 2006)
- d) 2 mg/kg PO two to three times a day (Collins 2006)

■ CATS:

For medical treatment of glaucoma:

- a) 3–4 mg/kg PO twice a day. Cats may not tolerate oral carbonic anhydrase inhibitors (CAIs) as well as dogs. Reported side effects include lethargy, inappetence, vomiting. Topical CAIs may be better tolerated. (Powell 2003)

Monitoring

- Intraocular pressure/tonometry
- Serum electrolytes, pH
- Baseline CBC with differential and periodic retests if using chronically
- Other adverse effects

Client Information

- If GI upset occurs, give with food.
- Notify veterinarian if abnormal bleeding or bruising occurs or if animal develops tremors or a rash.

Chemistry/Synonyms

A carbonic anhydrase inhibitor similar to dichlorphenamide, methazolamide occurs as a white to slightly yellow crystalline powder. It is very slightly soluble in water.

Methazolamide may also be known as: *GlaucTabs*®, *Glaumetax*®, *MZM*®, and *Neptazane*®.

Storage/Stability

Methazolamide tablets should be stored at room temperature in well-closed containers. Methazolamide tablets have an expiration date of 5 years after manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Methazolamide Tablets: 25 mg & 50 mg; generic; (Rx)

METHENAMINE MANDELATE METHENAMINE HIPPURATE

(meth-en-a-meen) Mandelamine®, Hiprex®, Urex®

URINARY ANTISEPTIC

Prescriber Highlights

- ▶ Theoretically, converted into an urinary antiseptic; efficacy somewhat questionable in small animals
- ▶ Contraindications: Hypersensitivity to it, renal insufficiency, severe hepatic impairment (due to ammonia production), or severe dehydration
- ▶ Adverse Effects: GI irritation; dysuria possible if used long-term
- ▶ Urine pH must be below 6.5 to be effective

Uses/Indications

Methenamine is used as an antimicrobial agent for the treatment and prophylaxis of recurrent urinary tract infection.

Pharmacology/Actions

In an acidic urinary environment (pH <6.5), methenamine is converted to formaldehyde. Formaldehyde is a non-specific antibacterial agent that exerts a bactericidal effect. It has activity on a variety of bacteria, including both gram-positive (*Staphylococcus aureus*, *S. epidermidis*, *Enterococcus*) and gram-negative organisms (*E. Coli*, *Enterobacter*, *Klebsiella*, *Proteus*, and *Pseudomonas aeruginosa*). Reportedly, methenamine has activity against fungal urinary tract infections.

Mandelic acid or hippuric acid are added primarily to help acidify the urine, but they also have some non-specific antibacterial activity. Bacterial resistance to formaldehyde, mandelic acid, or hippuric acid does not usually occur.

Pharmacokinetics

Human data: While methenamine and its salts are well absorbed from the GI tract, up to 30% of a dose may be hydrolyzed by gastric acid to ammonia and formaldehyde. With enteric-coated tablets, the amount hydrolyzed in the gut is reduced. While absorbed, plasma concentrations of both formaldehyde and methenamine are very low and have negligible systemic antibacterial activity. Methenamine does cross the placenta and is distributed into milk.

Within 24 hours, 70–90% of a dose is excreted unchanged into the urine. In acidic urine, conversion to ammonia and formaldehyde takes place, maximal hydrolysis occurs at urine pH's of 5.5 or less, but at pH's below 6.5 some conversion occurs. Peak formaldehyde concentrations occur in the urine at about 2 hours post-dose (3–8 hours with enteric-coated tablets).

Contraindications/Precautions/Warnings

Methenamine and its salts are contraindicated in patients known to be hypersensitive to it, with renal insufficiency, severe hepatic impairment (due to ammonia production), or severe dehydration.

Adverse Effects

The most likely adverse effect noted is gastrointestinal upset, with nausea, vomiting, and anorexia predominant. Some patients may develop dysuria, probably secondary to irritation due to high formaldehyde concentrations. Lipoid pneumonitis has been reported in some humans receiving prolonged therapy with the suspension. Potentially, systemic acidosis could occur.

Because methenamine requires acid urine to be beneficial, urine pH should ideally be kept at or below 5.5. Some urea-splitting bacteria (e.g., *Proteus* and some strains of staphylococci, *Enterobacter* and *Pseudomonas*) may increase urine pH. Addition of a urinary acidification program may be required using dietary modification and acidifying drugs (e.g., ascorbic acid, methionine, sodium biphosphate, ammonium chloride).

Reproductive/Nursing Safety

While methenamine crosses the placenta and lab animal studies have not demonstrated any teratogenic effects, it should be used with caution during pregnancy. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Methenamine enters milk but no adverse effects have not been reported in nursing children of mothers taking methenamine.

Overdosage/Acute Toxicity

Dogs have received single IV dosages of up to 600 mg/kg of methenamine hippurate without overt toxic effects. Large oral overdoses should be handled using established gut emptying protocols, maintaining hydration status and supporting as required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methenamine and may be of significance in veterinary patients:

- **SULFAMETHIAZOLE:** Use of methenamine with sulfamethiazole is not recommended. An insoluble precipitate may form.
- **URINE ALKALINIZING DRUGS** (e.g., calcium or magnesium containing antacids, carbonic anhydrase inhibitors, citrates, sodium bicarbonate, thiazide diuretics): Use of urinary alkalizing drugs may reduce the efficacy of the methenamine

Laboratory Considerations

- Urinary values of the following compounds may be falsely elevated: catecholamines, vanillylmandelic acid (VMA), 17-hydrocorticosteroid
- Falsely decreased urinary values of estriol or 5-HIAA may occur
- Methenamine may cause false-positive urine glucose determinations when using cupric sulfate solution (Benedict's Solution, *Clinitest*®) and false-negative tests utilizing the glucose oxidase (*Tes-Tape*®, *Clinistix*®) method

Doses

- **DOGS:**
 - a) Methenamine mandelate: 10 mg/kg PO q6h; use with ammonium chloride to acidify urine and increase effectiveness (Grauer 2003)
 - b) Methenamine mandelate: 10 mg/kg PO q6h (Bartges 2007)
- **CATS:**
 - a) Methenamine hippurate: 250 mg PO q12h (Papich 1992), (Bartges 2007)

Monitoring

- Urine pH
- Efficacy

Client Information

- Give after meals if GI distress occurs
- Encourage compliance

Chemistry/Synonyms

Methenamine is chemically unrelated to other anti-infective agents. It is commercially available in two salts, methenamine mandelate and methenamine hippurate. Methenamine mandelate occurs as a white, crystalline powder and contains approximately 48% methenamine and 52% mandelic acid. It is very soluble in water. Methenamine hippurate occurs as a white, crystalline powder with a sour taste and contains approximately 44% methenamine and 56% hippuric acid. It is freely soluble in water.

Methenamine may also be known as: hexamine amygdalate, hexamine mandelate, mandelato de metenamina, *Aci-steril*®, *Hiprex*®, *Mandelamine*®, *Reflux*®, *Urocedulamin*®, and *Urex*®.

Storage/Stability/Compatibility

Commercially available methenamine products should be stored at room temperature. Because acids hydrolyze methenamine to formaldehyde and ammonia, do not mix with acidic vehicles before administering. Methenamine is physically **incompatible** when mixed with most alkaloids and metallic salts (e.g., ferric, mercuric or silver salts). Ammonium salts or alkalis will darken methenamine.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Methenamine Mandelate Tablets: 0.5 gram & 1 gram; enteric-coated: 0.5 g & 1 g; *Mandelamine*® (Warner Chilcott); generic; (Rx)

Methenamine Mandelate Suspension: 0.5 g/5mL in 480 mL; generic; (Rx)

Methenamine Hippurate Tablets: 1 gram; *Hiprex*® (Hoechst Marion Roussel); *Urex*® (3M Pharm); (Rx)

METHIMAZOLE

(meth-*im*-a-zole) Tapazole®

Prescriber Highlights

- ▶ Used for medical treatment of feline hyperthyroidism
- ▶ Potentially, transdermal gels with methimazole may have efficacy in cats (or owners) that cannot tolerate oral dosing
- ▶ Contraindications: Hypersensitivity to it
- ▶ Caution: History of or concurrent hematologic abnormalities, liver disease, or autoimmune disease
- ▶ Adverse Effects: Most occur within first 3 mos. of treatment: vomiting, anorexia, & depression most frequent. Eosinophilia, leukopenia, & lymphocytosis are usually transient. Rare, but serious: self-induced excoriations, bleeding, hepatopathy, thrombocytopenia, agranulocytosis, positive direct antiglobulin test, & acquired myasthenia gravis
- ▶ Place kittens on milk replacer if mother receiving drug
- ▶ Very bitter taste

Uses/Indications

Methimazole is considered by most clinicians to be the agent of choice when using drugs to treat feline hyperthyroidism. Propylthiouracil has significantly higher incidences of adverse reactions when compared to methimazole and is rarely used today. Transdermal methimazole (in PLO gel; 2.5 mg twice daily) has been

used with some therapeutic success in cats that do not tolerate oral dosing. Efficacy may require four or more weeks to detect. Studies are ongoing.

Methimazole appears to be useful for the prophylactic prevention of cisplatin induced nephrotoxicity in dogs.

Pharmacology/Actions

Methimazole interferes with iodine incorporation into tyrosyl residues of thyroglobulin, thereby inhibiting the synthesis of thyroid hormones. It also inhibits iodinated tyrosyl residues from coupling to form iodothyronine. Methimazole has no effect on the release or activity of thyroid hormones already formed or in the general circulation.

Pharmacokinetics

Information on the pharmacokinetics of methimazole in cats is available (Trepanier, Peterson, and Aucoin 1989). These researchers reported that in normal cats, the bioavailability of the drug is highly variable (45–98%), as is the volume of distribution (0.12–0.84 L/kg). After oral dosing, plasma elimination half-life ranges from 2.3–10.2 hours. There is usually a 1–3 week lag time between starting the drug and significant reductions in serum T₄. In dogs, methimazole has a serum half-life of 8–9 hours. Methimazole apparently concentrates in thyroid tissue.

Contraindications/Precautions/Warnings

Methimazole is contraindicated in patients who are hypersensitive to it. It should be used very cautiously in patients with a history of or concurrent hematologic abnormalities, liver disease, or autoimmune disease.

Adverse Effects

Most adverse effects associated with methimazole use in cats occur within the first three months of therapy, with vomiting, anorexia, and depression/lethargy occurring most frequently. GI effects occur in about 10% of treated cats may be related to the drug's bitter taste or direct gastric irritation and are usually transient. Eosinophilia, leukopenia, thrombocytopenia, and lymphocytosis may be noted in approximately 15% of cats treated within the first 8 weeks of therapy. These hematologic effects usually are also transient and generally do not require drug withdrawal. Other more serious but rare adverse effects include: self-induced facial excoriations (2.3%), bleeding (2.3%), hepatopathy (1.5%), thrombocytopenia (2.7%), agranulocytosis (1.5%), and positive direct antiglobulin test (1.9%). These effects generally require withdrawal of the drug and adjunctive therapy. Up to 50% of cats receiving methimazole chronically (>6 months) will develop a positive ANA, requiring dosage reduction. Rarely cats will develop an acquired myasthenia gravis that requires either withdrawal or concomitant glucocorticoid therapy.

Reproductive/Nursing Safety

High levels of methimazole cross the placenta and may induce hypothyroidism in kittens born of queens receiving the drug. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Levels higher than those found in plasma are detected in human breast milk. It is suggested that kittens be placed on a milk replacer after receiving colostrum from mothers on methimazole.

Overdosage/Acute Toxicity

Acute toxicity that may be seen with overdosage include those that are listed above under Adverse Effects. Agranulocytosis, hepatopathy, and thrombocytopenias are perhaps the most serious effects

that may be seen. Treatment consists of following standard protocols in handling an oral ingestion (empty stomach, if not contraindicated, administer charcoal, etc.) and to treat symptomatically and supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methimazole and may be of significance in veterinary patients:

- **BUPROPION:** Potential for increased risk for hepatotoxicity; increased monitoring (LFT's) necessary
- **DIGOXIN:** Methimazole may decrease digoxin efficacy
- **WARFARIN:** Potential for decreased anticoagulant efficacy if methimazole added

Doses

■ DOGS:

As an investigative method to reduce nephrotoxicity associated with cisplatin therapy:

- a) 40 mg/kg IV over one minute prior to cisplatin. (Kitchell and Dhaliwal 2000) **Note:** No commercially available parenteral product in USA at time of writing.

■ CATS:

For hyperthyroidism:

- a) For cats with azotemia or for clients declining radioiodine: 1.25–5 mg per cat twice daily (start at lower end. (Trepanier 2007)
- b) Initially, 2.5 mg (total dose) PO once a day for 2 weeks. If adverse reactions not noted by owner, physical exam reveals no new problems, CBC and platelets are within normal limits, and serum T4 concentration is greater than 26 nmol/L after 2 weeks of therapy, the dose is increased to 2.5 mg PO twice daily and the same parameters are checked in another 2 weeks. The dosage should then be increased every 2 weeks by 2.5 mg per day until serum T4 is between 13 and 26 nmol/L or adverse effects develop. Serum T4 concentrations decline into the reference range within 1–2 weeks, once the cat is receiving an effective dose. (Nelson 2003b)
- c) If no signs of renal insufficiency/failure, begin at 5 mg (total dose) PO twice daily in cases with severely increased T4 levels. If renal insufficiency present (or not sure), start at 2.5 mg twice daily. If azotemia and overt renal failure, start at 1.25 mg twice a day. Monitor in 1–2 weeks (T4, CBC with platelet count, renal blood parameters, urinalysis). Monitor for other signs of adverse effects. Based on clinical signs and bloodwork, dose can be increased slowly. Monitor every 2–3 weeks for the first 3 months, then every 3–6 months thereafter. (Ward 2003)
- d) 5 mg two to three times a day. Goal is to maintain T4 in the low or low normal range. Recheck serum T4, CBC with platelets and chemistry panel at 2–3 week intervals. After first 3 months may recheck less frequently. (Taboada 2000)
- e) Methimazole (50 mg/mL; 5 mg/0.1 mL) in PLO for *transdermal administration*: 2.5 mg to inner pinna q12h. Person applying should wear gloves or finger cots. Somewhat lower efficacy than PO (67% vs 82% euthyroid at 4 weeks). Lower incidence of GI effects with transdermal (4% vs. 24%). No difference in facial excoriation, neutropenia, hepatotoxicity, or thrombocytopenia. Drawbacks for transdermal include: erythema at application site, increased cost, and stability of compounded med (2 weeks guaranteed stable). (Trepanier 2006)

Monitoring

During first 3 months of therapy (baseline values and every 2–3 weeks):

- CBC, platelet count
- Serum T4
- If indicated by symptomatology: liver function tests, ANA

After stabilized (at least 3 months of therapy):

- T4 at 3–6 month intervals
- Other diagnostic tests as dictated by adverse effects

Client Information

- It must be stressed to owners that this drug will decrease excessive thyroid hormones, but does not cure the condition and that compliance with the treatment regimen is necessary for success.

Chemistry/Synonyms

A thioimidazole-derivative antithyroid drug, methimazole occurs as a white to pale buff crystalline powder, having a faint characteristic odor and a melting point of 144–147°C. It is freely soluble (1 gram in 5 mL) in water or alcohol.

Methimazole may also be known as: thiamazole, mercazolylum, methylmercaptoimidazole, thiamazolum; tiamazol, *Antitiroide*®, *Danantizol*®, *Favistan*®, *Mercaptizol*®, *Metibasol*®, *Strumazol*®, *Tapazol*®, *Thacapzol*®, *Thycapzol*®, *Thyrozol*®, *Tirodril*®, and *Unimazole*®.

Storage/Stability

Methimazole tablets should be stored in well-closed, light-resistant containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Methimazole Tablets (plain & scored): 5 mg & 10 mg; *Tapazole*® (Monarch); generic; (Par Pharm); (Rx)

METHIONINE DL-METHIONINE RACEMETHIONINE

(me-thye-oh-neen) Ammonil®

URINARY ACIDIFIER; NUTRITIONAL

Prescriber Highlights

- Used primarily as a urinary acidifier; questionable efficacy in reducing stone formation
- Contraindications: Renal failure, pancreatic disease, hepatic insufficiency, preexisting acidosis, or urate calculi; not recommended for kittens
- Adverse Effects: Gastrointestinal distress (food may alleviate), Heinz-body hemolytic anemia (cats)
- Drug interactions

Uses/Indications

In small animals, methionine has been used primarily for its urine acidification effects in the treatment and prevention of certain types (e.g., struvite) of stone formation and to reduce ammoniacal urine odor. In food animals, it has been used as a nutritional supplement in swine and poultry feed and in the treatment of ketosis in cattle. It has been touted as a treatment for laminitis in horses and cattle (purportedly provides a disulfide bond substrate to maintain the hoof-pedal bone bond), but definitive studies demonstrating its effectiveness for this indication are lacking.

The drug is used in humans to reduce urine ammonia (pH) and odor.

Pharmacology/Actions

Methionine has several pharmacologic effects. It is an essential amino acid (l-form) and nutrient, a lipotrope (prevents or corrects fatty liver in choline deficiency), and a urine acidifier. Two molecules of methionine can be converted to 1 molecule of cysteine. Methionine supplies both sulfhydryl and methyl groups to the liver for metabolic processes. Choline is formed when methionine supplies a methyl group to ethanolamine. After methionine is metabolized, sulfate is excreted in the urine as sulfuric acid, thereby acidifying it.

Pharmacokinetics

No information is available on the pharmacokinetics of this agent in veterinary species or humans.

Contraindications/Precautions/Warnings

Methionine (in therapeutic doses) is contraindicated in patients with renal failure or pancreatic disease. If used in patients with frank hepatic insufficiency, methionine can cause increased production of mercaptan-like compounds and intensify the signs of hepatic dementia or coma. Methionine should not be given to animals with preexisting acidosis or urate calculi. It is not recommended for use in kittens.

Adverse Effects

At usual doses, gastrointestinal distress can occur; give with food to alleviate this effect and to enhance efficacy. Methionine may cause Heinz-body hemolytic anemia in cats. See Overdosage (below) for other potential adverse effects.

Unmonitored use with an acidifying diet (e.g., s/d, c/d), may lead to signs associated with overdose.

Reproductive/Nursing Safety

No specific information was located; methionine could, potentially, cause fetal acidosis.

Overdosage/Acute Toxicity

Methionine may be toxic to kittens who consume other cats' food in which methionine has been added. When methionine was administered at a dose of 2 grams orally per day to mature cats, anorexia, methemoglobinemia, Heinz body formation (with resultant hemolytic anemia), ataxia and cyanosis were noted. Metabolic acidosis, particularly in combination with an acidifying diet may occur with overdoses in any species. No specific information was located on the treatment of methionine overdosage.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methionine and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (*gentamicin*, *amikacin*, etc): The aminoglycosides are more effective in an alkaline medium; urine acidification may diminish these drugs effectiveness in treating bacterial urinary tract infections

- **ERYTHROMYCIN**: Is more effective in an alkaline medium; urine acidification may diminish erythromycin effectiveness in treating bacterial urinary tract infections

- **QUINIDINE**: Urine acidification may increase the renal excretion of quinidine

Doses

■ DOGS:

For urine acidification:

- a) In struvite dissolution therapy if diet and antimicrobials do not result in acid urine: 0.2–1 grams PO q8h (Lage, Polzin, and Zenoble 1988), (Kirk 1986)

■ CATS:

For urine acidification:

- a) 1000–1500 mg per day given in the food once daily (if diet and antimicrobials do not reduce pH) (Lewis, Morris, and Hand 1987)
- b) 0.2–1 grams PO once daily (Lage, Polzin, and Zenoble 1988)

■ CATTLE:

- a) 20–30 grams PO (Jenkins 1988)

■ HORSES:

- a) 22 mg/kg PO once daily for one week; then 11 mg/kg PO once daily for 1 week; then 5.5 mg/kg PO once daily for one week (Robinson 1987)
- b) 12.5 grams IV in one liter saline/dextrose solution (may be effective in Senecio-induced liver damage (Rossoff 1974)

Monitoring

- Urine pH (Urine pH's of ≤ 6.5 have been recommended as goal of therapy)
- Blood pH if signs of toxicity are present
- CBC in cats exhibiting signs of toxicity

Client Information

- Give with meals or mixed in food, unless otherwise instructed by veterinarian.

Chemistry/Synonyms

A sulfur-containing amino acid, methionine occurs as a white, crystalline powder with a characteristic odor. One gram is soluble in about 30 mL of water and it is very slightly soluble in alcohol. 74.6 mg is equivalent to 1 mEq of methionine.

Methionine may also be known as: dl-methionine, racemethionine, M, s-methionine, l-methionine, methioninum, *Acimethin*®, *Acimol*®, *Ammonil*®, *DL-Methionine Tablets*®, *M-Caps*®, *Methigel*®, *Methio-Form*®, *Methiotrans*®, *Methnine*®, *Neutrodor*®, *Pedameth*®, *Uracid*®, and *Uromethin*®.

Storage/Stability

Methionine should be stored at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Methionine is labeled for use in dogs, cats, and horses in pharmaceutical dosage forms. Products labeled as nutritional may be approved for use in other species. Depending on the product, methionine may be available without prescription. Methionine is an ingredient in many other nutritional products.

Methionine Tablets: 200 mg and 500 mg; *Ammonil*® Tablets (Virbac), *DL-Methionine Tablets*® (V.E.T.); (Rx). Approved for use in cats and dogs

Methionine Tablets Chewable: 500 mg; *Methio-Form*® (Vet-A-Mix); (Rx). Approved for use in dogs and cats.

Methionine Powder (concentration varies with product); Trade Names/Products include: d-l-methionine Powder (Butler, First Priority). Labeled for use in dogs and cats.

Methionine Gel: 400 mg (8%) in 120.5 g tubes. *Methigel*® (Vetoquinol); (OTC). Labeled for use in cats and dogs.

HUMAN-LABELED PRODUCTS:

Methionine Capsules: 200 mg & 500 mg; *M-Caps*® (Pal-Pak); *Uracid*® (Wesley); generic; (Tyson & Assoc); (Rx)

Methionine Tablets: 500 mg; generic; (Rx)

Topical Ointments, cream, lotion, pads and powder available.

METHOCARBAMOL

(meth-oh-kar-ba-mole) Robaxin®

MUSCLE RELAXANT

Prescriber Highlights

- ▶ Oral & injectable centrally acting muscle relaxant
- ▶ Contraindications: Food animals, renal disease (injectable only), hypersensitivity to it
- ▶ Adverse Effects: Sedation, salivation, emesis, lethargy, weakness, & ataxia
- ▶ Give IV slowly (don't exceed 2 mL/min); avoid extravasation; do not give SC

Uses/Indications

In dogs and cats, methocarbamol is indicated (FDA approved) "as adjunctive therapy of acute inflammatory and traumatic conditions of the skeletal muscle and to reduce muscular spasms." In horses, intravenous use is indicated (FDA approved) "as adjunctive therapy of acute inflammatory and traumatic conditions of the skeletal muscle to reduce muscular spasms, and effect striated muscle relaxation." (Package insert; *Robaxin*® V—Robins)

Pharmacology/Actions

Methocarbamol's exact mechanism of causing skeletal muscle relaxation is unknown. It is thought to work centrally, perhaps by general depressant effects. It has no direct relaxant effects on striated muscle, nerve fibers, or the motor endplate. It will not directly relax contracted skeletal muscles. The drug has a secondary sedative effect.

Pharmacokinetics

Limited pharmacokinetic data is available in veterinary species. In humans, methocarbamol has an onset of action of about 30 minutes after oral administration. Peak levels occur approximately 2 hours after dosing. Serum half-life is about 1–2 hours. The drug is metabolized and the inactive metabolites are excreted into the urine and the feces (small amounts).

In horses, plasma clearances appear to be dose dependent after IV administration (Muir, Sams, and Ashcraft 1984), lower clearances were measured after higher doses were given. The serum half-life of methocarbamol in the horse is approximately 60–70 minutes. Guaifenesin is a minor metabolite of methocarbamol, but because of very low concentrations, it probably has no clinical effect in the horse.

Contraindications/Precautions/Warnings

Because the injectable product contains polyethylene glycol 300, the manufacturer lists known or suspected renal pathology as a contraindication to injectable methocarbamol therapy. Polyethylene glycol 300 has been noted to increase preexisting acidosis and urea retention in humans with renal impairment.

Methocarbamol should not be used in patients hypersensitive to it or in animals to be used for food purpose.

Do not administer subcutaneously and avoid extravasation. Do not exceed 2 mL per minute when injecting IV in dogs and cats.

Adverse Effects

Side effects can include sedation, salivation, emesis, lethargy, weakness, and ataxia in dogs and cats. Sedation and ataxia are possible in horses. Because of its CNS depressant effects, methocarbamol may impair the abilities of working animals.

Reproductive/Nursing Safety

Methocarbamol should be used with caution during pregnancy as studies demonstrating its safety during pregnancy are lacking. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*). In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

It is not known whether methocarbamol is excreted in milk. Exercise caution, but the American Academy of Pediatrics classifies methocarbamol as compatible with women breastfeeding.

Overdosage/Acute Toxicity

Overdosage is generally characterized by CNS depressant effects (loss of righting reflex, prostration). Excessive doses in dogs and cats may be represented by emesis, salivation, weakness, and ataxia. If the overdose is after oral administration, emptying the gut may be indicated if the overdose was recent. Do not induce emesis if the patient's continued consciousness is not assured. Other clinical signs should be treated if severe and in a supportive manner.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methocarbamol and may be of significance in veterinary patients:

- **CNS DEPRESSANTS, OTHER:** Additive depression may occur when given with other CNS depressant agents
- **PYRIDOSTIGMINE:** One human patient, with myasthenia gravis and taking pyridostigmine, developed severe weakness after receiving methocarbamol

Laboratory Considerations

- Urinary values of the following compounds may be falsely elevated: **vanillylmandelic acid (VMA)**, or **5-HIAA** may occur

Doses

■ DOGS:

- a) Injectable: For relief of moderate conditions: 44 mg/kg IV; For controlling severe effects of strychnine and tetanus: 55–220 mg/kg IV, do not exceed 330 mg/kg/day. Administer half the estimated dose rapidly, then wait until animal starts to relax and continue administration to effect.

Tablets: Initially, 132 mg/kg/day PO divided q8h–q12h, then 61–132 mg/kg divided q8–12h. If no response in 5 days, discontinue. (Package insert; *Robaxin*®-V—Fort Dodge)

- b) For muscle relaxation for intervertebral disk disease: 15–20 mg/kg PO three times daily.
For muscle relaxation for certain toxicosis (e.g., strychnine, metaldehyde, tetanus): 150 mg/kg IV (Morgan 1988)
- c) For strychnine/brucine poisoning: Average first dose is 149 mg/kg IV, repeat half dose as needed (Bailey 1986a)
- d) To help control severe tremors associated with tremorgenic Mycotoxin intoxication: 55–220 mg/kg IV to effect at a rate no more than 2 mL/minute (Schell 2000)
- e) To help control tremors associated with Guarna (*Paillinia* spp.; caffeine) toxicity: 50–220 mg/kg IV, administered slowly and to effect; do not exceed 330 mg/kg/day. (Atkins 2006b)

■ CATS:

- a) Injectable: For relief of moderate conditions: 44 mg/kg IV; For controlling severe effects of strychnine and tetanus: 55–220 mg/kg IV, do not exceed 330 mg/kg/day. Administer half the estimated dose rapidly, then wait until animal starts to relax and continue administration to effect.
Tablets: Initially, 132 mg/kg/day PO divided q8h–q12h, then 61–132 mg/kg divided q8–12h. If no response in 5 days, discontinue. (Package insert, *Robaxin*®-V—Fort Dodge)

■ CATTLE:

- a) For treatment of CNS hyperactivity: 110 mg/kg IV (Bailey 1986b)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- a) For moderate conditions: 4.4–22 mg/kg IV to effect; for severe conditions: 22–55 mg/kg IV (Package insert, *Robaxin*®-V—Fort Dodge)
- b) 15–25 mg/kg IV by slow infusion (Robinson 1987)
- c) To give orally: Use 2–3 times the recommended IV dose (Cunningham, Fisher et al. 1992)
- d) For acute rhabdomyolysis: 15–25 mg/kg slow IV infusion. May repeat up to four times daily if needed to decrease muscle cramping. (Hanson 1999)

Monitoring

- Level of muscle relaxation/sedation

Client Information

- Animal's urine color may darken, but need not be a concern.

Chemistry/Synonyms

A centrally acting muscle relaxant related structurally to guaifenesin, methocarbamol occurs as a fine, white powder with a characteristic odor. In water, it has a solubility of 25 mg/mL. The pH of commercial injection is approximately 4–5.

Methocarbamol may also be known as: guaiphenesin carbamate, *Labycarbol*®, *Laxan*®, *Lumirelax*®, *Miowas*®, *Musxan*®, *Myocin*®, *Myomethol*®, *Ortoton*®, *Remisol*®, *Rexivin*®, *Robinax*®, and *Traumacut*®.

Storage/Stability/Compatibility

Methocarbamol tablets should be stored at room temperature in tight containers; the injection should be stored at room temperature and not frozen. Solutions prepared for IV infusion should not be refrigerated as a precipitate may form. Because a haze or precipitate may form, all diluted intravenous solutions should be physically inspected before administration.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Methocarbamol Tablets: 500 mg; *Robaxin*®V (Fort Dodge); (Rx). Approved for use in dogs and cats.

Methocarbamol Injection: 100 mg/mL in vials of 20 mL and 100 mL; *Robaxin*®-V (Fort Dodge); (Rx). Approved for use in dogs, cats, and horses not intended for food.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Methocarbamol Tablets: 500 mg & 750 mg; *Robaxin*® & *Robaxin*-750® (Schwarz Pharma); generic; (Rx)

Methocarbamol Injection: 100 mg/mL in 10 mL vials; *Robaxin*® (Wyeth-Ayerst); (Rx)

METHOHEXITAL SODIUM

(meth-oh-hex-i-tal) Brevital®

ULTRA-SHORT ACTING BARBITURATE

Prescriber Highlights

- Infrequently used ultra-short acting barbiturate for anesthesia induction, or for anesthesia for very short procedures, especially in sight hounds
- Contraindications: Absolute contraindications: absence of suitable veins for IV administration, history of hypersensitivity reactions to barbiturates, status asthmaticus. Relative contraindications: severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, & conditions where hypnotic effects may be prolonged (e.g., severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.)
- NOT recommended for use in cattle
- Avoid extravasation
- No analgesic or muscle relaxant properties
- Adverse Effects: Apnea, hypotension. Tremors, seizure during recovery; premed may help reduce/prevent rough recoveries
- C-IV Controlled Substance; relatively expensive

Uses/Indications

Methohexital is sometimes used in small animals as an ultrashort acting anesthetic agent, but, propofol has largely supplanted methohexital's use in small animals. However, because it is not dependent on redistribution to fat to reverse its effect, it may be useful in canine sight hound breeds. Because methohexital can induce anesthesia very rapidly, it may also be useful when general anesthesia must be administered to a patient with a full stomach, as an ET tube may be placed rapidly before aspiration of vomitus can occur.

Pharmacology/Actions

Methohexital is an ultra-short acting methylated oxybarbiturate anesthetic agent. It is about twice as potent as thiopental and has a duration of action about ½ as long. Like all the barbiturates, methohexital acts by depressing the reticular activating center of the brain.

Pharmacokinetics

After IV injection, methohexital rapidly causes anesthesia (15–60 seconds). Its distribution half-life is 5–6 minutes. When used alone, a single dose will cause surgical anesthesia for 5–15 minutes. Unlike the thiobarbiturates, methohexital is rapidly metabolized by the liver and is not dependent on redistribution to fat to reverse its effects. No drug is detectable in the body 24 hours after administration. Its elimination half-life is reported to be 3–5 hours. Recovery times in small animals average 30 minutes.

Contraindications/Precautions/Warnings

Contraindicated in patients hypersensitive to barbiturates or who do not have adequate veins for safe IV administration. Relative contraindications include: seizure-prone animals, severe cardiovascular disease or preexisting ventricular arrhythmias, shock, increased intracranial pressure, myasthenia gravis, asthma, and conditions where hypnotic effects may be prolonged (e.g., severe hepatic disease, myxedema, severe anemia, excessive premedication, etc.). These relative contraindications do not preclude the use of methohexital, but dosage adjustments must be considered and the drug must be given slowly and cautiously.

Because of its unpredictability in cattle, it is not recommended for use in this species.

Adverse Effects

Methohexital can cause profound respiratory depression. The lethal dose may only be 2–3 times that of the anesthetic dose. Because excitation (including muscle tremors and seizures) can occur upon recovery, methohexital is generally recommended for use with a premed. Postoperative seizures have been reported and can be treated with IV diazepam.

In small animals, methohexital may induce rougher recoveries when compared to thiopental.

Because of its rapid elimination and very short action, there is a possibility that methohexital's effects may diminish before inhalant anesthesia takes full effect.

Too rapid an injection may lead to apnea and hypotension. Barbiturates do not provide analgesia or any muscle relaxation.

Because it can be very irritating to tissues and localized necrosis can occur in soft tissue, methohexital solutions must be only given IV, and perivascular injection must be avoided. Extravasation injuries can be treated with multiple infiltrates of sterile normal saline. Lidocaine can be injected to reduce pain.

Reproductive/Nursing Safety

While safety of methohexital has not been established in pregnancy, doses of up to 7 times those of humans given to pregnant rabbits and rats resulted in no overt teratogenicity or fetal harm. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Small amounts of thiopental have been detected in milk following administration of large doses to humans. It is unlikely that methohexital poses much risk to nursing offspring.

Overdosage/Acute Toxicity

See Adverse Effects above; give dosages carefully.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methohexital and may be of significance in veterinary patients:

■ **CNS DEPRESSANT DRUGS:** When used with other CNS depressant drugs, methohexital may have additive effects.

Doses

■ DOGS:

- For induction with premedication: 5 mg/kg; give $\frac{1}{2}$ – $\frac{3}{4}$ to $\frac{3}{4}$ of dose over 10 seconds. In 30 seconds if adequate plane is not reached to allow intubation, give additional drug. Delay will result in poor induction due to rapid redistribution. (McKelvey and Hollingshead 2000)
- For induction or sole anesthetic in non-premedicated dogs or cats: 11 mg/kg IV, give approximately $\frac{1}{2}$ the dose rapidly and then titrate to effect. If premedicated, give 5.5–6.6 mg/kg IV, 10–30% is given rapidly IV and then the remainder titrated to effect. (Paddleford 1999)

■ CATS:

- For induction or sole anesthetic in non-premedicated dogs or cats: 11 mg/kg IV, give approximately $\frac{1}{2}$ the dose rapidly and then titrate to effect. If premedicated, give 5.5–6.6 mg/kg IV, 10–30% is given rapidly IV and then the remainder titrated to effect. (Paddleford 1999)

Monitoring

- Plane of anesthesia
- Respiratory rate/depth
- Cardiac rate, rhythm and blood pressure
- Upon recovery, monitor for CNS stimulation (seizures)

Client Information

- Methohexital should be used in a setting only where adequate monitoring and support are available.

Chemistry/Synonyms

An ultra-short acting barbiturate agent, methohexital occurs as a white, crystalline powder. It is freely soluble in water.

Methohexital sodium may also be known as: compound 25398, enallnymalnatrimum, methohexitone sodium, *Brevimytal*®, *Brevital*®, and *Brietal*®.

Storage/Stability/Compatibility

Methohexital sodium powder for injection should be stored at room temperature (less than 25°C). Preferably, reconstitute the powder for injection with sterile water for injection. D5W or 0.9% sodium chloride may also be used, particularly when making concentrations of 0.2% (to avoid extreme hypotonicity). While the manufacturer states not to make concentrations greater than 1%, some veterinary anesthesiologists will make concentrations of up to 6% (especially when using in large animals). Do not use solutions with bacteriostatic agents to prepare the solution.

After reconstituting with sterile water for injection, solutions are stable for at least 6 weeks at room temperature. As long as the solution remains clear and colorless, the manufacturer states that it is permissible to use. Solutions of D5W or normal saline are not stable for much more than 24 hours after reconstituting.

Methohexital solutions are alkaline. Do not mix with acidic drugs (e.g., atropine or succinylcholine). Refer to specialized references before attempting to mix methohexital with another drug. Methohexital is **incompatible** with silicone. Do not allow contact with silicone-treated rubber stoppers or silicone treated parts of disposable syringes.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Methohexital Sodium Powder for Injection: 2.5 g in 20mL vials; *Brevital® Sodium* (Monarch); (Rx, C-IV)

METHOTREXATE

METHOTREXATE SODIUM

(meth-oh-trex-ate) MTX, Amethopterin

ANTINEOPLASTIC, IMMUNOSUPPRESSIVE

Prescriber Highlights

- ▶ Antineoplastic/immunosuppressant used primarily for lymphomas & some solid tumors in dogs & cats
- ▶ Contraindications: Preexisting bone marrow depression, severe hepatic or renal insufficiency, or hypersensitivity to the drug
- ▶ Caution: If patient susceptible or has preexisting clinical signs associated with the adverse reactions associated with this drug (see below)
- ▶ Adverse Effects: GI (diarrhea, nausea, & vomiting); Higher dosage: listlessness, GI toxicity (ulcers, mucosal sloughing, stomatitis), hematopoietic toxicity (nadir at 4–6 days), hepatopathy, renal tubular necrosis, alopecia, depigmentation, pulmonary infiltrates & fibrosis; anaphylaxis (rare)
- ▶ Avoid human exposure
- ▶ Teratogenic; may affect spermatogenesis
- ▶ Determine dosages accurately
- ▶ Drug interactions

Uses/Indications

Indicated for lymphomas and some solid tumors in dogs and cats (see the Doses section and the recommended treatment protocol references at the end of this section). In human medicine, methotrexate is also being used to treat refractory rheumatoid arthritis and severe psoriasis.

Pharmacology/Actions

An S-phase specific antimetabolite antineoplastic agent, methotrexate competitively inhibits folic acid reductase, preventing the reduction of dihydrofolate to tetrahydrofolate and affecting production of purines and pyrimidines. Rapidly proliferating cells (e.g., neoplasms, bone marrow, GI tract epithelium, fetal cells, etc.) are most sensitive to the drug's effects.

Dihydrofolate reductase has a much greater affinity for methotrexate than either folic acid or dihydrofolic acid and coadministration of folic acid will not reduce methotrexate's effects. Leucovorin calcium, a derivative of tetrahydrofolic acid, can block the effects of methotrexate.

Methotrexate also has immunosuppressive activity, possibly due to its effects on lymphocyte replication. Tumor cells have been noted to develop resistance to methotrexate that may be due to decreased cellular uptake of the drug.

Pharmacokinetics

Methotrexate is well absorbed from the GI tract after oral administration of dosages <30 mg/m² with a bioavailability of about 60%. In humans, peak levels occur within 4 hours after oral dosing, and between 30 minutes and 2 hours after IM injection.

Methotrexate is widely distributed in the body and is actively transported across cell membranes. Highest concentrations are found in the kidneys, spleen, gallbladder, liver, and skin. When given orally or parenterally, methotrexate does not reach therapeutic levels in the CSF. When given intrathecally, methotrexate attains therapeutic levels in the CSF and also passes into the systemic circulation. Methotrexate is about 50% bound to plasma proteins and crosses the placenta.

Methotrexate is excreted almost entirely by the kidneys via both glomerular filtration and active transport. Serum half-life is less than 10 hours and generally between 2–4 hours.

Contraindications/Precautions/Warnings

Methotrexate is contraindicated in patients with preexisting bone marrow depression, severe hepatic or renal insufficiency, or hypersensitivity to the drug. It should be used with caution in patients who are susceptible to, or have preexisting clinical signs associated with, the adverse reactions associated with this drug.

When administering MTX, either wear gloves or immediately wash hands after handling. Gloves are particularly important if handling split, broken, or crushed tablets. Preparation of intravenous solutions should ideally be performed in a vertical laminar flow hood.

Adverse Effects

In dogs and cats, gastrointestinal side effects are most prevalent with diarrhea, nausea, inappetance (especially cats) and vomiting (especially dogs) seen. Higher dosages may lead to listlessness, GI toxicity (ulcers, mucosal sloughing, stomatitis), hematopoietic toxicity (nadir at 4–6 days), hepatopathy, renal tubular necrosis, alopecia, depigmentation, pulmonary infiltrates, and fibrosis. CNS toxicity (encephalopathy) may be noted if methotrexate is given intrathecally. Rarely, anaphylaxis may be seen.

Reproductive/Nursing Safety

Methotrexate is teratogenic, embryotoxic, and may affect spermatogenesis in male animals. In humans, the FDA categorizes this drug as category X for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: C (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

Methotrexate is contraindicated in nursing mothers. It is excreted in breast milk in low concentrations with a milk:plasma ratio of 0.08:1. Nursing offspring should be switched to milk replacer if the dam requires methotrexate.

Overdosage/Acute Toxicity

Acute overdosage in dogs is associated with exacerbations of the adverse effects outlined above, particularly myelosuppression and acute renal failure. Acute tubular necrosis is secondary to drug precipitation in the tubules. In dogs, the maximally tolerated dose is reported to be 0.12 mg/kg q24h for 5 days.

Treatment of acute oral overdoses include emptying the gut and preventing absorption using standard protocols if the ingestion is recent. Additionally, oral neomycin has been suggested to help pre-

vent absorption of MTX from the intestine. In order to minimize renal damage, forced alkaline diuresis should be considered. Urine pH should be maintained between 7.5–8 by the addition of 0.5–1 mEq/kg of sodium bicarbonate per 500 mL of IV fluid.

Leucovorin calcium is specific therapy for methotrexate overdoses. It should be given as soon as possible, preferably within the first hour and, definitely, within 48 hours. Doses of leucovorin required are dependent on the MTX serum concentration. Humans having serum concentrations greater than 5×10^{-7} M at 48 hours are likely to develop severe toxicity. Leucovorin in doses ranging from 25–200 mg/m² every 6 hours doses is given until serum levels fall below 1×10^{-8} M. Dogs treated with leucovorin at 15 mg/m² every 3 hours IV for 8 doses, then IM q6h for 8 doses were able to tolerate MTX doses as high as 3 g/m² (O’Keefe and Harris 1990). Another dose of 3 mg/m² for leucovorin in dogs has also been suggested (Coppoc 1988).

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methotrexate (MTX) and may be of significance in veterinary patients:

- **AMIODARONE:** Prolonged PO administration of amiodarone (>2 weeks) may inhibit MTX metabolism
- **ASPARAGINASE:** Asparaginase given concomitantly with MTX may decrease MTX efficacy
- **AZATHIOPRINE:** Potential for increased risk for hepatic toxicity
- **CHLORAMPHENICOL:** May displace MTX from plasma proteins increasing risk for toxicity, but also may reduce MTX absorption and enterohepatic recirculation
- **CISPLATIN:** May have synergistic action with MTX, but alter the renal elimination of MTX
- **CYCLOSPORINE:** May increase MTX levels
- **FOLIC ACID:** May reduce MTX efficacy, but folate deficiency increases MTX toxicity
- **NEOMYCIN (oral):** Oral neomycin may decrease the absorption of oral methotrexate if given concomitantly
- **NSAIDS, SALICYLATES:** In humans, severe hematologic and GI toxicity has resulted in patients receiving both MTX and non-steroidal antiinflammatory agents; use caution in dogs also on MTX
- **PENICILLINS:** May decrease MTX renal elimination
- **PROBENECID:** May inhibit the tubular secretion of MTX and increase its half-life
- **PRIMETHAMINE:** Primethamine, a similar folic acid antagonist, may increase MTX toxicity and should not be given to patients receiving MTX
- **RETINOIDS:** Potential for increased risk for hepatic toxicity
- **SULFASALAZINE:** Potential for increased risk for hepatic toxicity
- **SULFONAMIDES:** May displace MTX from plasma proteins increasing risk for toxicity
- **TETRACYCLINES:** May displace MTX from plasma proteins increasing risk for toxicity, but also may reduce MTX absorption and enterohepatic recirculation
- **THEOPHYLLINES:** MTX may reduce theophylline elimination
- **TRIMETHOPRIM/SULFA:** Rarely, may increase myelosuppression of MTX
- **VACCINES, LIVE:** Live virus vaccines should be used with caution, if at all during therapy

Laboratory Considerations

- Methotrexate may interfere with the microbiologic assay for **folic acid**.

Doses

Dosages of methotrexate sodium are expressed in terms of methotrexate as are the dosage forms. For more information on using MTX as part of chemotherapy protocols, refer to the protocols found in the appendix or other dosages/protocols found in numerous references, including: *Withrow and MacEwen’s Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

■ DOGS:

For susceptible neoplastic diseases (usually as part of a multi-drug protocol):

- a) As part of the LMP protocol for maintenance of canine lymphoma: Chlorambucil 20 mg/m² PO every 15 days; Methotrexate 2.5–5 mg/m² PO twice a week; Prednisone 20 mg/m² PO every other day. When Vincristine is added it is at a dose of 0.5–0.7 mg/m² and is given every 15 days alternating weeks with the chlorambucil. (Berger 2005)
- b) 2.5 mg/m² PO 2–3 times weekly; 0.3–0.8 mg/m² IV every 7 days (O’Keefe and Harris 1990)
- c) “High dose therapy”: 5–10 mg/m² PO, IV, IM or intrathecally followed 2–4 hours later with leucovorin at 3 mg/m² “Normal dose therapy”: 2.5 mg/m² once daily. Adjust dosage/frequency according to toxicity (Thompson 1989a)
- d) For lymphoma (as part of protocol): 0.5 mg/kg IV (maximum dose 25 mg) on day 14 (Matus 1989)
- e) In combination with other antineoplastics (per protocol) 5 mg/m² PO twice weekly or 0.8 mg/kg IV every 21 days; alternatively 2.5 mg/m² PO daily (USPC 1990)

■ CATS:

For susceptible neoplastic diseases (usually as part of a multi-drug protocol):

- a) 2.5 mg/m² PO 2–3 times weekly; 0.3–0.8 mg/m² IV every 7 days (O’Keefe and Harris 1990)
- b) For lymphoma (as part of protocol—see reference): 0.8 mg/kg IV on day 14 with 5 mg prednisone twice daily PO (Matus 1989)
- c) In combination with other antineoplastics (per protocol) 5 mg/m² PO twice weekly (USPC 1990)

Monitoring

■ Efficacy

■ Toxicity:

- a) Monitor for clinical signs of GI irritation and ulceration
- b) Complete blood counts (with platelets) should be performed weekly early in therapy and eventually every 4–6 weeks when stabilized. If WBC is $<4000/\text{mm}^3$ or platelet count is $<100,000/\text{mm}^3$ therapy should be discontinued
- c) Baseline renal function tests. Continue to monitor if abnormal
- d) Baseline hepatic function tests. Monitor liver enzymes on a regular basis during therapy.

Client Information

- Clients must be briefed on the possibilities of severe toxicity developing from this drug, including drug-related mortality.
- Clients should contact the veterinarian if the patient exhibits clinical signs of profound depression, abnormal bleeding (including bloody diarrhea) and/or bruising.

- Wear gloves when administering tablets (particularly if crushed or split); if gloves are not used, wash hands thoroughly after handling tablets.

Chemistry/Synonyms

A folic acid antagonist, methotrexate is available commercially as the sodium salt. It occurs as a yellow powder that is soluble in water. Methotrexate sodium injection has a pH of 7.5–9.

Methotrexate and methotrexate sodium may also be known as: MTX, amethopterin, 4-Amino-4-deoxy-10-methylpteroyl-L-glutamic acid, 4-Amino-10-methylfolic acid, CL-14377, alpha-methopterin, methotrexatum, metotrexato, NSC-740, WR-19039; there are many trade names available.

Storage/Stability/Compatibility

Methotrexate sodium tablets should be stored at room temperature (15–30°C) in well-closed containers and protected from light. The injection and powder for injection should be stored at room temperature (15–30°C) and protected from light.

Methotrexate sodium is reportedly physically **compatible** with the following intravenous solutions and drugs: Amino acids 4.25%/dextrose 25%, D5W, sodium bicarbonate 0.05 M, cephalothin sodium, cytarabine, 6-mercaptopurine sodium, sodium bicarbonate, and vincristine sulfate. In syringes, methotrexate is physically **compatible** with: bleomycin sulfate, cyclophosphamide, doxorubicin HCl, fluorouracil, furosemide, leucovorin calcium, mitomycin, vinblastine sulfate, and vincristine sulfate.

Methotrexate sodium **compatibility information conflicts** or is dependent on diluent or concentration factors with the following drugs or solutions: heparin sodium and metoclopramide HCl. Compatibility is dependent upon factors such as pH, concentration, temperature and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Methotrexate sodium is reportedly physically **incompatible** when mixed with the following solutions or drugs: bleomycin sulfate (as an IV additive only; **compatible** in syringes and Y-lines), fluorouracil (as an IV additive only; **compatible** in syringes and Y-lines), prednisolone sodium phosphate, droperidol, and ranitidine HCl.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Methotrexate Sodium Tablets (plain & scored): 2.5 mg, 5 mg, 7.5 mg, 10 mg and 15 mg; *Rheumatrex® Dose Pack* (STADA); *Trexal®* (Barr); generic; (Rx)

Methotrexate Sodium Injection: 25 mg/mL (as base) in 2 mL & 10 mL vials; preservative-free in 2 mL, 4 mL, 8 mL, 10 mL, 20 mL, and 40 mL single-use vials; *Methotrexate LPF® Sodium* (Xanodyne); generic; (Rx)

Methotrexate Powder for Injection, lyophilized: preservative free in 1 g in single-use vials; generic; (Rx)

METHOXYFLURANE

(meth-ox-ee-floo-rane) Penthrane®

INHALANT ANESTHETIC

Prescriber Highlights

- Infrequently used inhalant general anesthetic agent
- Contraindications: Preexisting renal or hepatic disease
- Caution (benefits vs. risks): Increased CSF or head injury, or myasthenia gravis.
- Adverse Effects: Potential nephrotoxicity
- Drug interactions

Uses/Indications

Methoxyflurane is an inhalant anesthetic, but it is rarely used today primarily due to its potential for causing nephrotoxicity, slow onset of action (a short-acting barbiturate is often used as an induction agent), and prolonged recovery time. However, it does produce some muscle relaxation and analgesia, even at relatively low concentrations and can be administered without a precision vaporizer as it will vaporize to a maximum of about 3%.

Pharmacology/Actions

While the precise mechanism that inhalant anesthetics exert their general anesthetic effects is not precisely known, they may interfere with functioning of nerve cells in the brain by acting at the lipid matrix of the membrane. Some key pharmacologic effects noted with methoxyflurane include: CNS depression, depression of body temperature regulating centers, increased cerebral blood flow, respiratory depression, hypotension, vasodilatation, and myocardial depression (less so than with halothane) and muscular relaxation.

Pharmacokinetics

Methoxyflurane is rapidly absorbed from the alveoli, but it has a comparatively slow onset of activity. It is rapidly distributed into the CNS and crosses the placenta. Approximately 35% of a dose is eliminated via the lungs and approximately 50% is metabolized in the liver; substantial amounts of inorganic fluoride are formed which are excreted by the kidneys.

Minimal Alveolar Concentration (MAC; %) in oxygen reported for methoxyflurane in various species: Dog = 0.23; Cat = 0.23; Horse = 0.22; Human = 0.16. Several factors may alter MAC (acid/base status, temperature, other CNS depressants on board, age, ongoing acute disease, etc.).

Contraindications/Precautions/Warnings

Methoxyflurane should be used cautiously, if at all, in patients with preexisting renal or hepatic disease. It should be used with caution (benefits vs. risks) in patients with increased CSF or head injury, or myasthenia gravis.

Adverse Effects

The most troublesome adverse effect associated with methoxyflurane is its potential for causing nephrotoxicity, particularly with prolonged procedures in patients predisposed to nephrotoxicity. Dogs with normal renal function are probably less susceptible to this effect than are humans, unless concomitantly receiving nephrotoxic agents (NSAIDs, etc.).

While methoxyflurane, potentially, may cause hepatotoxicity, this apparently occurs rarely and may be associated with hypoxic episodes. Nevertheless, it should be used with caution in patients with preexisting hepatic dysfunction.

Reproductive/Nursing Safety

Studies are not definitive, but methoxyflurane may cause teratogenic effects; other inhalant anesthetic agents may be safer alternatives. If methoxyflurane is used during delivery or C-section, oxygen may need to be given to newborns after delivery. In a system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: *C (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)*

Overdosage/Acute Toxicity

Overdosage or acute toxicities may cause circulatory depression and hypotension, cardiac arrhythmias, bradycardia, prolonged respiratory depression, emergence delirium, or malignant hyperthermic crises.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methoxyflurane and may be of significance in veterinary patients:

- **CLINDAMYCIN, LINCOMYCIN:** Should be used with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur
- **NEPHROTOXIC DRUGS, OTHER** (e.g., aminoglycosides, amphotericin B, cisplatin, NSAIDs, penicillamine): Because of methoxyflurane's potential for causing nephrotoxicity, it should not be used concurrently with other nephrotoxic drugs
- **NON-DEPOLARIZING NEUROMUSCULAR BLOCKING AGENTS:** Should be used with caution with halogenated anesthetic agents as additive neuromuscular blockade may occur
- **SUCCINYLCHOLINE:** Concomitant administration of succinylcholine with inhalation anesthetics may induce increased incidences of cardiac effects (bradycardia, arrhythmias, sinus arrest and apnea) and, in susceptible patients, malignant hyperthermia as well
- **SYMPATHOMIMETICS** (dopamine, epinephrine, norepinephrine, ephedrine, metaraminol, etc.): While methoxyflurane sensitizes the myocardium to the effects of sympathomimetics less so than halothane, arrhythmias may still result; caution and monitoring are advised

Doses

- **DOGS & CATS:**
 - a) 3% (induction); 0.5–1.5% (maintenance) (Papich 1992)
- **RUMINANTS & SWINE:**
 - a) Induction 1%; maintenance 0.5% (Howard 1993)

Monitoring

- Respiratory and ventilatory status
- Cardiac rate/rhythm; blood pressure (particularly with “at risk” patients)
- Level of anesthesia
- Renal function tests, if patient's post-operative urine output is excessive or markedly reduced

Chemistry/Synonyms

An inhalant general anesthetic agent, methoxyflurane occurs as a clear, mobile liquid. It has a characteristic fruity odor. Methoxyflurane is very slightly soluble in water and miscible with alcohol or olive oil. At 20°C, methoxyflurane's specific gravity is 1.420–1.425.

Methoxyflurane may also be known as NSC-110432, *Penthane®* and *Penthrox®*.

Storage/Stability/Compatibility

Store at room temperature in tight, light-resistant containers. Protect from freezing. Methoxyflurane is very soluble in rubber and soda lime. Avoid contact with polyvinyl chloride (PVC) plastics as they can be extracted by methoxyflurane.

Methoxyflurane contains an antioxidant (BHT) that may accumulate in the vaporizer causing a yellow to brown discoloration. Do not use discolored solutions. Discolored vaporizer and wick may be cleaned with diethyl ether (all ether must be removed before reuse).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Methoxyflurane in 15 mL and 125 mL; *Penthane®* (Abbott); (Rx)

METHYLENE BLUE

(meth-i-leen)

ANTIDOTE

Prescriber Highlights

- Thiazine dye used to primarily treat methemoglobinemia in ruminants
- Contraindications: Cats (most agree), lactating dairy animals, renal insufficiency; hypersensitive to methylene blue; or given as an intraspinal (intrathecal) injection
- Not very effective in horses
- Adverse Effects: Heinz body anemia or other red cell morphological changes, methemoglobinemia, & decreased red cell life spans. Cats most sensitive, but to a lesser degree, dogs & horses also.
- A 180-day slaughter withdrawal time has been suggested, but 14 days may be sufficient (see doses)

Uses/Indications

Methylene blue is used primarily for treating methemoglobinemia secondary to oxidative agents (nitrates, chlorates) in ruminants. It is also employed occasionally as adjunctive or alternative therapy for cyanide toxicity.

Intra-operative methylene blue is also being used to preferentially stain islet-cell tumors of the pancreas in dogs in order to aid in their surgical removal or in determining the animal's prognosis.

Pharmacology/Actions

Methylene blue is rapidly converted to leucomethylene blue in tissues. This compound serves as a reducing agent that helps to convert methemoglobin (Fe⁺⁺⁺) to hemoglobin (Fe⁺⁺). Methylene blue is an oxidizing agent, and, if high doses (species dependent) are administered, may actually cause methemoglobinemia.

Pharmacokinetics

Methylene blue is absorbed from the GI tract, but is usually administered parenterally in veterinary medicine. It is excreted in the urine and bile, primarily in the colorless form, but some unchanged drug may be also excreted.

Contraindications/Precautions/Warnings

Methylene blue is contraindicated in patients with renal insufficiency, or are hypersensitive to methylene blue. It cannot be given as an intraspinal (intrathecal) injection. Because cats may develop Heinz body anemia and methemoglobinemia secondary to methylene blue, it is considered contraindicated in this species by most clinicians. Methylene blue is considered relatively ineffective in reducing methemoglobin in horses.

Adverse Effects

The greatest concern with methylene blue therapy is the development of Heinz body anemia or other red cell morphological changes, methemoglobinemia, and decreased red cell life spans. Cats tend to be very sensitive to these effects; the drug is usually considered contraindicated in them, but dogs and horses can also develop these effects at relatively low dosages.

When injected SC or if extravasation occurs during IV administration, necrotic abscesses may develop.

Reproductive/Nursing Safety

Safe use of this agent during pregnancy has not been demonstrated. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

No information on lactation safety was found.

Overdosage/Acute Toxicity

The LD₅₀ for IV administered 3% methylene blue is approximately 43 mg/kg in sheep.

Drug Interactions

None reported

Laboratory Considerations

- Methylene blue can cause a green-blue color in urine and may affect the accuracy of **urinalysis**.

Doses

■ DOGS:

To preferentially stain islet-cell tumors of the pancreas:

- 3 mg/kg in 250 mL sterile normal saline and administered IV over 30–40 minutes intraoperatively. Initial tumor staining requires approximately 20 minutes after infusion has begun and is maximal at about 25–35 minutes after infusion is started. Tumors generally appear to be a reddish-violet in color versus a dusky blue (background staining). (Fingeroth and Smeak 1988)

To treat methemoglobinemia:

- Secondary to phenol exposure: A single, slow IV infusion of 4 mg/kg of methylene blue; may use with 20 mg/kg ascorbic acid PO (Dorman and Clark 2000)
- For severe methemoglobinemia: 1 mg/kg as a 1% solution given slowly IV over several minutes. A dramatic response should occur during the first 30 minutes after treatment. It may be repeated if necessary, but it should be used cautiously as can cause Heinz body anemia. Measure hematocrit for 3 days after treatment. (Harvey 2006)

■ CATS:

To treat methemoglobinemia:

- Secondary to phenol exposure: A single, slow IV infusion of 1.5 mg/kg of methylene blue, may use with 20 mg/kg ascorbic acid PO (Dorman and Clark 2000)
- 1–1.5 mg/kg IV one time only (Christopher 2000)
- For severe methemoglobinemia: 1 mg/kg as a 1% solution given slowly IV over several minutes. A dramatic response should occur during the first 30 minutes after treatment. It may be repeated if necessary, but it should be used cautiously as can cause Heinz body anemia. Measure hematocrit for 3 days after treatment. (Harvey 2006)

■ RUMINANTS:

Note: When used in food animals, FARAD recommends a minimum milk withdrawal time of 4 days after the last treatment. Because of concerns of carcinogenicity, an extremely conservative withdrawal time for meat of 180 days has been recommended; however, available data suggest that a much shorter withdrawal time of 14 days would be sufficient. (Haskell, Payne et al. 2005)
For methemoglobin-producing toxins (nitrites, nitrates, chlorates):

- Cattle: 8.8 mg/kg by slow IV using a maximum of a 1% solution; repeat if necessary. To prevent hypotension during nitrite poisoning, give a sympathomimetic drug such as epinephrine or ephedrine. (Bailey 1986b)
- Food animals: 4–15 mg/kg IV; may be repeated in 6–8 hours (Post and Keller 2000)
- Cattle, sheep: 8.8 mg/kg slow IV as a 1% solution in normal saline; may repeat carefully in 15–30 minutes if response is not satisfactory. Other species should use 4.4 mg/kg dosage rate (as above). (Hatch 1988b)
- For nitrate poisoning in cattle: 5–15 mg/kg as a 1% solution in physiologic saline. With severe cases, repeat treatment at a lower dose may be required. In animals that do not succumb, recovery occurs by 24 hours. (Hall 2006)

For cyanide toxicity:

- 4–6 g IV per 454 kg (1000 lb.) of body weight (Oehme 1986b)

■ HORSES:

For methemoglobinemia secondary to chlorate toxicity:

- 4.4 mg/kg as 1% solution by intravenous drip; may repeat in 15–30 minutes if clinical response is not obtained. (Schmitz 2004)

Monitoring

- Methemoglobinemia
- Red cell morphology, red cell indices, hematocrit, hemoglobin

Client Information

- Because of the potential toxicity of this agent and the seriousness of methemoglobin-related intoxications, this drug should be used with close professional supervision only.
- Methylene blue may be very staining to clothing or skin. Removal may be accomplished using hypochlorite solutions (bleach).

Chemistry/Synonyms

A thiazine dye, methylene blue occurs as dark green crystals or crystalline powder that has a bronze-like luster. It may have a slight odor and is soluble in water and sparingly soluble in alcohol. When dissolved, a dark blue solution results. Commercially available methylene blue injection (human-labeled) has a pH from 3–4.5.

Methylene blue may also be known as: methylthioninium chloride, azul de metileno, blu di metilene, CI basic blue 9, colour index no. 52015, methylene blue, methylenii caeruleum, methylthioninii chloridum, schultz no. 1038, tetramethylthionine chloride trihydrate, *Azul Metile*®, *Collubleu*®, *Desmoidpillen*®, *Vitableu*®, *Urolene Blue*® and *Zumetil*®.

Storage/Stability/Compatibility

Unless otherwise instructed by the manufacturer, store methylene blue at room temperature. Methylene blue is reportedly physically **incompatible** when mixed with caustic alkalies, dichromates, iodides, and oxidizing or reducing agents.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None approved as pharmaceuticals for internal use. A 1% (10 mg/mL) methylene blue solution (Centaur) is labeled for animal use as a dye, laboratory indicator and reagent. It is available in pint and gallon bottles. Methylene Blue, USP powder may be available from chemical supply houses

HUMAN-LABELED PRODUCTS:

Methylene Blue Injection: 10 mg/mL in 1 mL and 10 mL amps; generic; (Rx)

Methylene Blue Tablets: 65 mg; *Urolene Blue*® (Star); (Rx)

METHYLPHENIDATE

(meth-ill-fen-i-date) Ritalin®

CNS STIMULANT

Prescriber Highlights

- ▶ Amphetamine-like drug that may be useful for treating cataplexy/narcolepsy or hyperkinesia/hyperactivity in dogs
- ▶ Use with caution in dogs with seizure disorders, cardiac disease/hypertension, or in aggressive animals
- ▶ Adverse effects are primarily CNS stimulation-related
- ▶ Class-II controlled drug in USA

Uses/Indications

Methylphenidate may be useful for treating cataplexy/narcolepsy or hyperactivity in dogs.

Pharmacology/Actions

Methylphenidate has stimulating effects on the central nervous and respiratory systems similar to that of amphetamines. It also has weak sympathomimetic activity, and at normal dosages has little effect on peripheral circulation.

Pharmacokinetics

Specific pharmacokinetic studies in dogs were not located. In humans, methylphenidate (regular tablets) is rapidly and well absorbed from the GI tract. Food in the GI tract may increase the rate, but not the extent, of drug absorbed. Peak levels occur about 2 hours post-dose. The drug is extensively metabolized during the first-pass; protein binding is low. Terminal elimination half-life is approximately 3 hours; less than 1% is excreted unchanged in the urine.

Contraindications/Precautions/Warnings

The risks associated with methylphenidate should be carefully considered before using this drug in dogs with seizure disorders, cardiac disease/hypertension, or in aggressive animals.

Adverse Effects

Most likely adverse effects to be encountered include increased heart and respiratory rates, anorexia, tremors and hyperthermia (particularly exercised-induced).

Reproductive/Nursing Safety

In humans, the FDA categorizes methylphenidate as a category C drug for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). Methylphenidate was associated with teratogenic effects in rabbits, but at massive dosages (200 mg/kg/day).

It is unknown if methylphenidate enters maternal milk.

Overdosage/Acute Toxicity

In dogs, dosages of 1 mg/kg (or below) can cause toxic reactions; there is one report of a fatality after a dog ingested 3.1 mg/kg, but research dogs have survived doses of 20 mg/kg/day for 90 days. A cat given a 5 mg tablet of methylphenidate, showed signs of tremors, agitation, mydriasis, tachycardia, tachypnea and hypertension; signs resolved 25 hours post-ingestion with supportive care (dark cage, diazepam, fluids).

Expected signs associated with an overdose in dogs are generally CNS over-stimulation and excessive sympathomimetic effects and can include: hyperactivity, salivation, diarrhea, head bobbing, agitation, tachycardia, hypertension, tremors, seizures, and hyperthermia. Consider the dosage form (extended-release vs. regular tablets) when considering treatment options and expected onset and duration of effects. Employ treatment using standard gut detoxification techniques (emetic, activated charcoal, cathartic, etc.); however, emesis should be avoided in animals displaying signs associated with toxicity or that are otherwise at risk for emesis-related adverse effects. Treatment is basically supportive by controlling signs associated with toxicity. Phenothiazines (e.g., acepromazine, chlorpromazine) may be useful in controlling agitation; beta-blockers can help control tachycardia; external cooling may be used for hyperthermia; and cyproheptadine may help prevent serotonin syndrome.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methylphenidate and may be of significance in veterinary patients:

- **ANTICONSULSANTS** (phenobarbital, primidone, phenytoin): Methylphenidate may increase serum levels
- **CLONIDINE**: Rare cases (in humans) of cardiovascular effects (including death); mechanism not understood and causality not established
- **HYPOTENSIVE DRUGS**: Methylphenidate may reduce effects
- **MAO INHIBITORS** (including amitraz and potentially, selegiline): Could lead to hypertensive crisis
- **SSRI ANTIDEPRESSANTS** (e.g., fluoxetine, sertraline, etc.): Methylphenidate may inhibit metabolism and increase levels
- **TRICYCLIC ANTIDEPRESSANTS** (e.g., amitriptyline, clomipramine, etc.): Methylphenidate may inhibit metabolism and increase levels
- **WARFARIN**: Methylphenidate may inhibit warfarin metabolism and increase INR

Laboratory Considerations

No specific laboratory interactions were noted for this drug.

Doses**■ DOGS:**

- For treatment of narcolepsy/cataplexy: 5–10 mg (total dose) PO once daily. (Joseph 2000)
- For treatment of narcolepsy/cataplexy (to supplement imipramine at 0.5–1 mg/kg PO q8–12h): Methylphenidate: 0.25–0.5 mg/kg PO or 5–10 mg (total dose) PO q12–24h (Shell 2003b)
- For treatment of hyperkinesia: 5–20 mg (total dose) q8–12h; give for 3 days and assess for improvement of target behaviors (anxiety, overactivity, learning ability) (Siebert 2003c)
- For hyperkinesia-hyperactivity: Small dogs: 5+ mg total dose PO q12h; Large Dogs: 20–40 mg total dose PO q12h (Virga 2002)

Monitoring

- Clinical efficacy
- Occasional physical exam to monitor vital signs, body weight
- In humans, it is recommended to do periodic CBC with differential and platelet counts during prolonged therapy.

Client Information

- Clients should understand that this drug has significant potential for abuse by humans and to keep it safely secure.
- Clients should report untoward stimulatory effects to the veterinarian.
- If using an extended-release product, do not crush tablet or capsule.

Chemistry/Synonyms

A CNS stimulant related to amphetamines, methylphenidate HCl occurs as fine, white odorless, crystalline powder. It is feely soluble in water and soluble in alcohol.

Methylphenidate may also be known as: *Attenta*®, *Daytrana*®, *Equasym*®, *Focalin*®, *Metadate ER*®, *Methylin*®, *Rilatine*®, *Riphenidate*®, *Ritalina*®, *Ritalin*®, *Ritaline*®, *Ritaphen*®, *Rubifen*®, or *Tranquilyn*®.

Storage/Stability

Unless otherwise noted on the label, methylphenidate tablets and extended-release tablets and capsules should be stored in tight, light-resistant containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Methylphenidate Tablets: 5 mg, 10 mg & 20 mg; Chewable Tablets: 2.5 mg, 5 mg & 10 mg; Extended-Release Tablets: 10 mg, 18 mg, 20 mg, 27 mg, 36 mg & 54 mg; Extended-Release Capsules: 20 mg, 30 mg & 40 mg; *Methylin*® (Mallinckrodt; Alliant); *Ritalin*®, *Ritalin*® LA, & *Ritalin-SR*® (Novartis); *Metadate ER*® (Mallinckrodt; Celltech); *Concerta*® (McNeil); (Rx; C-II)

Methylphenidate Oral Solution: 5 mg/5 mL & 10 mg/5 mL in 500 mL; *Methylin*® (Alliant); (Rx; C-II)

Methylphenidate Transdermal Patch: 10 mg, 15 mg, 20 mg & 30 mg; *Daytrana*® (Shire); (Rx; C-II)

METHYLPREDNISOLONE

METHYLPREDNISOLONE

ACETATE

METHYLPREDNISOLONE

SODIUM SUCCINATE

(meth-ill-pred-niss-oh-lone) Medrol®, Depo-Medrol®

GLUCOCORTICOID**Prescriber Highlights**

- Oral & parenteral glucocorticoid that is 4–5X more potent than hydrocortisone; no appreciable mineralocorticoid activity
- Contraindicated (relatively): Systemic fungal infections, manufacturer lists: “in viral infections, . . . animals with arrested tuberculosis, peptic ulcer, acute psychoses, corneal ulcer, & Cushingoid syndrome. The presence of diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, & active tuberculosis necessitates carefully controlled use.”
- Therapy goal is to use as much as is required & as little as possible for as short an amount of time as possible
- Primary adverse effects are “Cushingoid” in nature with sustained use
- Many potential drug & lab interactions

Uses/Indications

Glucocorticoids have been used in an attempt to treat practically every malady that afflicts man or animal, but there are three broad uses and dosage ranges for use of these agents. **1)** Replacement of glucocorticoid activity in patients with adrenal insufficiency, **2)** as an antiinflammatory agent, and **3)** as an immunosuppressive. Among some of the uses for glucocorticoids include treatment of: endocrine conditions (e.g., adrenal insufficiency), rheumatic diseases (e.g., rheumatoid arthritis), collagen diseases (e.g., systemic lupus), allergic states, respiratory diseases (e.g., asthma), dermatologic diseases (e.g., pemphigus, allergic dermatoses), hematologic disorders (e.g., thrombocytopenias, autoimmune hemolytic anemias), neoplasias, nervous system disorders (increased CSF pressure), GI diseases (e.g., ulcerative colitis exacerbations), and renal diseases (e.g., nephrotic syndrome). Some glucocorticoids are used topically in the eye and skin for various conditions or are injected intra-articularly or intra-lesionally. The above listing is certainly not complete. For specific dosages and indications refer to the Doses section.

Pharmacology/Actions

Methylprednisolone may be administered either orally or parenterally. Its relative antiinflammatory potency is approximately 5 times that of cortisol. It has negligible mineralocorticoid activity.

Glucocorticoids have effects on virtually every cell type and system in mammals. An overview of the effects of these agents follows:

CARDIOVASCULAR SYSTEM: Glucocorticoids can reduce capillary permeability and enhance vasoconstriction. A relatively clinically insignificant positive inotropic effect can occur after glucocorticoid administration. Increased blood pressure can result from both the

drugs' vasoconstrictive properties and increased blood volume that may be produced.

CELLS: Glucocorticoids inhibit fibroblast proliferation, macrophage response to migration inhibiting factor, sensitization of lymphocytes, and the cellular response to mediators of inflammation. Glucocorticoids stabilize lysosomal membranes.

CNS/AUTONOMIC NERVOUS SYSTEM: Glucocorticoids can lower seizure threshold, alter mood and behavior, diminish the response to pyrogens, stimulate appetite, and maintain alpha rhythm. Glucocorticoids are necessary for normal adrenergic receptor sensitivity.

ENDOCRINE SYSTEM: When animals are not stressed, glucocorticoids will suppress the release of ACTH from the anterior pituitary, thereby reducing or preventing the release of endogenous corticosteroids. Stress factors (e.g., renal disease, liver disease, diabetes) may sometimes nullify the suppressing aspects of exogenously administered steroids. Release of thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), prolactin, and luteinizing hormone (LH) may all be reduced when glucocorticoids are administered at pharmacological doses. Conversion of thyroxine (T₄) to triiodothyronine (T₃) may be reduced by glucocorticoids; and plasma levels of parathyroid hormone increased. Glucocorticoids may inhibit osteoblast function. Vasopressin (ADH) activity is reduced at the renal tubules and diuresis may occur. Glucocorticoids inhibit insulin binding to insulin-receptors and the post-receptor effects of insulin.

HEMATOPOIETIC SYSTEM: Glucocorticoids can increase the numbers of circulating platelets, neutrophils, and red blood cells, but inhibit platelet aggregation. Decreased amounts of lymphocytes (peripheral), monocytes, and eosinophils are seen as glucocorticoids can sequester these cells into the lungs and spleen and prompt decreased release from the bone marrow. Removal of old red blood cells is diminished. Glucocorticoids can cause involution of lymphoid tissue.

GI TRACT AND HEPATIC SYSTEM: Glucocorticoids increase the secretion of gastric acid, pepsin, and trypsin. They alter the structure of mucin and decrease mucosal cell proliferation. Iron salts and calcium absorption decrease while fat absorption increases. Hepatic changes can include increased fat and glycogen deposits within hepatocytes, increased serum levels of alanine aminotransferase (ALT) and gamma-glutamyl transpeptidase (GGT). Significant increases can be seen in serum alkaline phosphatase levels. Glucocorticoids can cause minor increases in BSP (bromosulphophthalein) retention time.

IMMUNE SYSTEM (also see Cells and Hematopoietic System): Glucocorticoids can decrease circulating levels of T-lymphocytes; inhibit lymphokines; inhibit neutrophil, macrophage, and monocyte migration; reduce production of interferon; inhibit phagocytosis and chemotaxis; antigen processing; and diminish intracellular killing. Specific acquired immunity is affected less than nonspecific immune responses. Glucocorticoids can also antagonize the complement cascade and mask the clinical signs of infection. Mast cells are decreased in number and histamine synthesis is suppressed. Many of these effects only occur at high or very high doses and there are species differences in response.

METABOLIC EFFECTS: Glucocorticoids stimulate gluconeogenesis. Lipogenesis is enhanced in certain areas of the body (e.g., abdomen) and adipose tissue can be redistributed away from the extremities to the trunk. Fatty acids are mobilized from tissues and their oxidation is increased. Plasma levels of triglycerides, cholesterol, and glycerol are increased. Protein is mobilized from most areas of the body (not the liver).

MUSCULOSKELETAL: Glucocorticoids may cause muscular weakness (also caused if there is a lack of glucocorticoids), atrophy, and osteoporosis. Bone growth can be inhibited via growth hormone and somatomedin inhibition, increased calcium excretion, and inhibition of vitamin D activation. Resorption of bone can be enhanced. Fibrocartilage growth is also inhibited.

OPHTHALMIC: Prolonged corticosteroid use (both systemic or topically to the eye) can cause increased intraocular pressure and glaucoma, cataracts, and exophthalmos.

RENAL, FLUID, & ELECTROLYTES: Glucocorticoids can increase potassium and calcium excretion; sodium and chloride reabsorption, and extracellular fluid volume. Hypokalemia and/or hypocalcemia occur rarely. Diuresis may occur following glucocorticoid administration.

SKIN: Thinning of dermal tissue and skin atrophy can be seen with glucocorticoid therapy. Hair follicles can become distended and alopecia may occur.

Contraindications/Precautions/Warnings

The manufacturer (Upjohn Veterinary) states that the drug (tablets) should not be used in dogs or cats "in viral infections, ... animals with arrested tuberculosis, peptic ulcer, acute psychoses, corneal ulcer, and Cushingoid syndrome. The presence of diabetes, osteoporosis, chronic psychotic reactions, predisposition to thrombophlebitis, hypertension, CHF, renal insufficiency, and active tuberculosis necessitates carefully controlled use."

The injectable acetate product is contraindicated as outlined above when used systemically. When injected intrasynovially, intratendinously, or by other local means, it is contraindicated in the "presence of acute local infections."

Systemic use of glucocorticoids is generally considered contraindicated in systemic fungal infections (unless used for replacement therapy in Addison's), when administered IM in patients with idiopathic thrombocytopenia, and in patients hypersensitive to a particular compound. Use of sustained-release injectable glucocorticoids is considered contraindicated for chronic corticosteroid therapy of systemic diseases.

Animals that have received glucocorticoids systemically other than with "burst" therapy, should be tapered off the drugs. Patients who have received the drugs chronically should be tapered off slowly as endogenous ACTH and corticosteroid function may return slowly. Should the animal undergo a "stressor" (e.g., surgery, trauma, illness, etc.) during the tapering process or until normal adrenal and pituitary function resume, additional glucocorticoids should be administered.

Adverse Effects

Adverse effects are generally associated with long-term administration of these drugs, especially if given at high dosages or not on an alternate day regimen. Effects generally are manifested as clinical signs of hyperadrenocorticism. When administered to young, growing animals, glucocorticoids can retard growth. Many of the potential effects, adverse and otherwise, are outlined above in the Pharmacology section.

In dogs, polydipsia (PD), polyphagia (PP), and polyuria (PU) may all be seen with short-term "burst" therapy as well as with alternate-day maintenance therapy on days when administering the drug. Adverse effects in dogs can include dull, dry haircoat, weight gain, panting, vomiting, diarrhea, elevated liver enzymes, pancreatitis, GI ulceration, lipidemias, activation or worsening of diabetes mellitus, muscle wasting, and behavioral changes (depression, lethargy, viciousness). Discontinuation of the drug may be necessary; changing to an alternate steroid may also alleviate the problem. With the exception of PU/PD/PP, adverse effects associated with

antiinflammatory therapy are relatively uncommon. Adverse effects associated with immunosuppressive doses are more common and, potentially, more severe.

Cats generally require higher dosages than dogs for clinical effect, but tend to develop fewer adverse effects. Occasionally, polydipsia, polyuria, polyphagia with weight gain, diarrhea, or depression can be seen. Long-term high dose therapy can lead to “Cushingoid” effects, however.

Administration of dexamethasone or triamcinolone may play a role in the development of laminitis in horses.

Reproductive/Nursing Safety

Glucocorticoids are probably necessary for normal fetal development. They may be required for adequate surfactant production, myelin, retinal, pancreas and mammary development. Excessive dosages early in pregnancy may lead to teratogenic effects. In horses and ruminants, exogenous steroid administration may induce parturition when administered in the latter stages of pregnancy. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Use with caution in nursing dams. Glucocorticoids unbound to plasma proteins will enter milk. High dosages or prolonged administration to mothers may, potentially, inhibit growth, interfere with endogenous corticosteroid production or cause other unwanted effects in nursing offspring. However, in humans, several studies suggest that amounts excreted in breast milk are negligible when methylprednisolone doses are less than or equal to 8 mg/day. Larger doses for short periods may not harm the infant.

Overdosage/Acute Toxicity

Glucocorticoids when given short-term are unlikely to cause harmful effects, even in massive dosages. One incidence of a dog developing acute CNS effects after accidental ingestion of glucocorticoids has been reported. Should clinical signs occur, use supportive treatment if required.

Chronic usage of glucocorticoids can lead to serious adverse effects. Refer to Adverse Effects above for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methylprednisolone and may be of significance in veterinary patients:

- **AMPHOTERICIN B:** Administered concomitantly with glucocorticoids may cause hypokalemia; in humans, there have been cases of CHF and cardiac enlargement reported after using methylprednisolone to treat Amphotericin B adverse effects
- **ANALGESICS, OPIATE and/or ANESTHETICS, LOCAL (epidural injections):** Combination with glucocorticoids in epidurals has caused serious CNS injuries and death; do not use more volume than very small intrathecal test doses of these agents with glucocorticoids
- **ANTICHOLINESTERASE AGENTS** (e.g., **pyridostigmine**, **neostigmine**, etc.): In patients with myasthenia gravis, concomitant glucocorticoid and anticholinesterase agent administration may lead to profound muscle weakness. If possible, discontinue anticholinesterase medication at least 24 hours prior to corticosteroid administration
- **ASPIRIN:** Glucocorticoids may reduce salicylate blood levels
- **BARBITURATES:** May increase the metabolism of glucocorticoids and decrease blood levels
- **CYCLOPHOSPHAMIDE:** Glucocorticoids may inhibit the hepatic metabolism of cyclophosphamide; dosage adjustments may be required

- **CYCLOSPORINE:** Concomitant administration of glucocorticoids and cyclosporine may increase the blood levels of each, by mutually inhibiting the hepatic metabolism of each other; the clinical significance of this interaction is not clear
- **DIURETICS, POTASSIUM-DEPLETING** (e.g., **spironolactone**, **triamterene**): Administered concomitantly with glucocorticoids may cause hypokalemia
- **EPHEDRINE:** May reduce methylprednisolone blood levels
- **ESTROGENS:** The effects of methylprednisolone, and possibly other glucocorticoids, may be potentiated by concomitant administration with estrogens
- **INSULIN:** Insulin requirements may increase in patients receiving glucocorticoids
- **KETOCONAZOLE** and other **AZOLE ANTIFUNGALS:** May decrease the metabolism of glucocorticoids and increase methylprednisolone blood levels; ketoconazole may induce adrenal insufficiency when glucocorticoids are withdrawn by inhibiting adrenal corticosteroid synthesis
- **MACROLIDE ANTIBIOTICS** (**erythromycin**, **clarithromycin**): May decrease the metabolism of glucocorticoids and increase methylprednisolone blood levels
- **MITOTANE:** May alter the metabolism of steroids; higher than usual doses of steroids may be necessary to treat mitotane-induced adrenal insufficiency
- **NSAIDs:** Administration of ulcerogenic drugs with glucocorticoids may increase the risk of gastrointestinal ulceration
- **PHENOBARBITAL:** May increase the metabolism of glucocorticoids and decrease methylprednisolone blood levels
- **RIFAMPIN:** May increase the metabolism of glucocorticoids and decrease methylprednisolone blood levels
- **VACCINES:** Patients receiving corticosteroids at immunosuppressive dosages should generally not receive live attenuated-virus vaccines as virus replication may be augmented; a diminished immune response may occur after vaccine, toxoid, or bacterin administration in patients receiving glucocorticoid
- **WARFARIN:** Methylprednisolone may affect INR's; monitor

Laboratory Considerations

- Methylprednisolone acetate may reduce **post-ACTH cortisol** concentrations by 20–50%.
- Glucocorticoids may increase **serum cholesterol**
- Glucocorticoids may increase **serum and urine glucose** levels
- Glucocorticoids may decrease **serum potassium**
- Glucocorticoids can suppress the release of thyroid stimulating hormone (TSH) and reduce **T₃ & T₄** values. Thyroid gland atrophy has been reported after chronic glucocorticoid administration. Uptake of **I¹³¹** by the thyroid may be decreased by glucocorticoids.
- Reactions to **skin tests** may be suppressed by glucocorticoids
- False-negative results of the **nitroblue tetrazolium** test for systemic bacterial infections may be induced by glucocorticoids
- Glucocorticoids may cause **neutrophilia** within 4–8 hours after dosing and return to baseline within 24–48 hours after drug discontinuation
- Glucocorticoids can cause **lymphopenia** which can persist for weeks after drug discontinuation in dogs

Doses

■ DOGS:

As an antiinflammatory agent:

- a) Initially 1–2 mg/kg/day divided two to three times daily for 5 to 10 days. After clinical signs are suppressed, consolidate dose (1–2 mg/kg/day) and give at 7–10 AM once a day for 1 week. Then reduce dose to 0.5–1 mg/kg/day for 5–7 days. Convert to alternate day dosing by giving 1–2 mg/kg on alternate mornings. Reduce dosage by ½ each week until a minimally effective dose is reached. (Kemppainen 1986)
- b) Methylprednisolone: 1 mg/kg PO q8h; methylprednisolone acetate: 1 mg/kg IM every 14 days (Jenkins 1985)
- c) Methylprednisolone acetate: 1.1 mg/kg SC or IM; effects (for dermatologic indications) generally last for 1–3 weeks (Scott 1982)
- d) For labeled uses:
Oral:
Dogs weighing 5–15 lbs: 2 mg
Dogs weighing 15–40 lbs: 2–4 mg
Dogs weighing 40–80 lbs: 4–8 mg
These total daily doses should be divided and given 6–10 hours apart.
Intramuscularly: 2–120 mg IM (average 20 mg); depending on breed (size), severity of condition, and response. May repeat at weekly intervals or in accordance with the severity of the condition and the response. (Package insert; *Depo-Medrol*®—Upjohn) The manufacturer has specific directions for use of the drug intrasynovially. It is recommended to refer directly to the package insert for more information.

As an immunosuppressant:

- a) Pulse therapy to induce remission or control of autoimmune skin diseases: Methylprednisolone sodium succinate 11 mg/kg in 250 mL D₅W infused IV over 1 hour for 3 consecutive days. Cimetidine 4 mg/kg PO q8h may also be given to reduce GI implications. After day 3, begin oral prednisone maintenance at 1.1 mg/kg q24–48h. Azathioprine can also be added during maintenance phase. (White, Stewart, and Bernstein 1987)

For adjunctive medical therapy of spinal cord trauma [**Note:** At present (2007), use of corticosteroids for use in CNS/spinal chord trauma is very controversial]:

- a) Methylprednisolone sodium succinate: Initially, 30 mg/kg IV; 2 hours later give 15 mg/kg IV. Then give 10 mg/kg IV or SC 4 times a day for 24–36 hours. Reduce dosage gradually over next 7 days. Cimetidine may be helpful in preventing hemorrhagic gastroenteritis associated with high dose glucocorticoids. (Schunk 1988a)
- b) Two dosing schedules:
30 mg/kg IV followed 2 hours later with a constant IV infusion of 5.4 mg/kg/hr for 24–48 hours
30 mg/kg IV loading dose, followed by 15 mg/kg IV 2 hours later then every 6 hours for 24–48 hours (Thomas 2002)

For adjunctive therapy for various forms of shock [**Note:** At present (2007), use of corticosteroids for use in shock is very controversial]:

- a) Methylprednisolone sodium succinate: 30–35 mg/kg IV (Kemppainen 1986)

For intralesional (sub-lesional) use:

- a) A sufficient volume of 20 mg/mL methylprednisolone acetate is used to undermine the lesion (10–40 mg total dose) (Scott 1982)

■ CATS:

As an antiinflammatory agent:

- a) Methylprednisolone acetate: 5.5 mg/kg SC or IM (average sized cat = 20 mg); effects (for dermatologic indications) generally last for 1 week to 6 months (Scott 1982)
- b) For labeled uses:
Oral:
Cats weighing 5–15 lbs: 2 mg
Cats weighing >15 lbs: 2–4 mg
These total daily doses should be divided and given 6–10 hours apart
Intramuscularly: up to 20 mg (average 10 mg) IM; depending on breed (size), severity of condition, and response. May repeat at weekly intervals or in accordance with the severity of the condition and the response. (Package insert; *Depo-Medrol*®—Upjohn)

For adjunctive treatment of cerebral ischemic necrosis:

- a) Methylprednisolone sodium succinate: 30 mg/kg IV (Kornegay 2003a)

For eosinophilic ulcer:

- a) Methylprednisolone acetate 20 mg SC every 2 weeks for 2–3 doses. If chronic case, maintenance therapy may be required at 20 mg SC as needed. May also consider adding megestrol acetate. (DeNovo, Potter, and Woolfson 1988)

As alternate adjunctive therapy for feline plasma cell gingivitis-pharyngitis:

- a) Methylprednisolone acetate 10–20 mg SC as needed. May also consider adding megestrol acetate. (DeNovo, Potter, and Woolfson 1988)

As an antiinflammatory for the adjunctive treatment of feline asthma:

- a) Methylprednisolone acetate: 2 mg/kg (dosage interval or route not specified) (Papich 1986)
- b) Methylprednisolone acetate: 1–2 mg/kg IM (dosage interval not specified) (Noone 1986)

For adjunctive therapy of flea allergy:

- a) Methylprednisolone acetate: 5 mg/kg SC; generally will keep animal comfortable for 3–6 weeks. Do not use more often than every 2 months. (Kwochka 1986)

For adjunctive treatment of idiopathic feline miliary dermatoses:

- a) Methylprednisolone acetate: 5 mg/kg SC; if favorable response is noted, may repeat same dosage two times at 2–3 week intervals. Thereafter, do not use more often than every 2 months. (Kwochka 1986)

For adjunctive treatment of pulmonary edema secondary to blood transfusion reactions:

- a) 30 mg/kg repeated every 6 hours (route not specified) (Auer and Bell 1986)

For intralesional (sub-lesional) use:

- a) A sufficient volume of 20 mg/mL methylprednisolone acetate is used to undermine the lesion (10–40 mg total dose) (Scott 1982)

■ HORSES:

As an antiinflammatory (glucocorticoid effects):

- a) Methylprednisolone: 0.5 mg/kg PO; Methylprednisolone sodium succinate: 0.5 mg/kg IV or IM (Robinson 1987)
- b) For labeled uses: Methylprednisolone acetate 200 mg IM repeated as necessary (Package insert; *Depo-Medrol*®—Upjohn). The manufacturer has specific directions for use of the drug intrasynovially. It is recommended to refer directly to the package insert for more information.

- c) For intra-articular use: Methylprednisolone acetate 100 mg IA (McClure 2002)

For shock [**Note:** At present (2007), use of corticosteroids for use in shock is very controversial]: Methylprednisolone sodium succinate:

- a) 10–20 mg/kg IV (Robinson 1987)

Monitoring

Monitoring of glucocorticoid therapy is dependent on its reason for use, dosage, agent used (amount of mineralocorticoid activity), dosage schedule (daily versus alternate day therapy), duration of therapy, and the animal's age and condition. The following list may not be appropriate or complete for all animals; use clinical assessment and judgment should adverse effects be noted:

- Weight, appetite, signs of edema
- Serum and/or urine electrolytes
- Total plasma proteins, albumin
- Blood glucose
- Growth and development in young animals
- ACTH stimulation test if necessary

Client Information

- Clients should carefully follow the dosage instructions and should not discontinue the drug abruptly without consulting with veterinarian beforehand.
- Clients should be briefed on the potential adverse effects that can be seen with these drugs and instructed to contact the veterinarian should these effects become severe or progress.

Chemistry/Synonyms

Methylprednisolone is a synthetically produced glucocorticoid. Both the free alcohol and the acetate ester occur as odorless, white or practically white, crystalline powder. They are practically insoluble in water and sparingly soluble in alcohol.

Methylprednisolone sodium succinate occurs as an odorless, white or nearly white, hygroscopic, amorphous solid. It is very soluble in both water and alcohol.

Methylprednisolone may also be known as: 6alpha-methylprednisolone, methylprednisolonum, NSC-19987, *A-Methapred*®, *Alergolon*®, *Caberdelta M*®, *Cipridanol*®, *Cortisolona*®, *Depo-Medrol*®, *Esametone*®, *Firmacort*®, *Medrate*®, *Medrol*®, *Medrone*®, *Mega-Star*®, *Metilpren*®, *Metisona*®, *Methapred*®, *Metypred*®, *Metysolon*®, *Predni M*®, *Prednilen*®, *Reactenol*®, *Sieropresol*®, *Solomet*®, *Solu-Medrol*®, *Summicort*® and *Urbason*®.

Storage/Stability/Compatibility

Commercially available products of methylprednisolone should be stored at room temperature (15–30°C); avoid freezing the acetate injection. After reconstituting the sodium succinate injection, store at room temperature and use within 48 hours; only use solutions that are clear.

Methylprednisolone sodium succinate injection is reportedly physically **compatible** with the following fluids and drugs: amino acids 4.25%/dextrose 25%, amphotericin B (limited amounts), chloramphenicol sodium succinate, cimetidine HCl, clindamycin phosphate, dopamine HCl, heparin sodium, metoclopramide, norepinephrine bitartrate, penicillin G potassium, sodium iodide/aminophylline, and verapamil.

The following drugs and fluids have either been reported to be physically **incompatible** when mixed with methylprednisolone sodium succinate, compatible dependent upon concentration, or data conflicts: D5/half normal saline, D5 normal saline (80 mg/L reported compatible), D5W (up to 5 grams/L reported compatible), Lactated Ringer's (up to 80 mg/L reported compatible), normal

saline (data conflicts; some reports of up to 60 grams/liter compatible), calcium gluconate, cephalothin sodium (up to 500 mg/L in D5W or NS compatible), glycopyrrolate, insulin, metaraminol bitartrate, nafcillin sodium, penicillin G sodium, and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Methylprednisolone Tablets: 4 mg tablets, *Medrol*®; (Pfizer); (Rx). Approved for use in dogs and cats.

Methylprednisolone Acetate Injection: 20 mg/mL in 10 mL and 20 mL vials, and 40 mg/mL in 5 mL vials; *Depo-Medrol*® (Pfizer); generic; (Rx). Approved for IM and intrasynovial injection in dogs and horses; for IM injection in cats.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

A 10 ppb tolerance has been established for methylprednisolone in milk.

HUMAN-LABELED PRODUCTS:

Methylprednisolone Tablets: 2 mg, 4 mg, 8 mg, 16 mg, 24 mg & 32 mg; *Medrol*® (Upjohn); generic; (Rx)

Methylprednisolone Acetate Injection: 20 mg/mL, 40 mg/mL, 80 mg/mL suspension in 1 mL, 5 mL and 10 mL vials; *Depo-Medrol*® (Upjohn); generic; (Rx)

Methylprednisolone Sodium Succinate Powder for Injection: 40 mg/vial in 1 and 3 mL vials and 1 mL *Univials* and *Act-O-Vials*; 125 mg/vial in 2 mL and 5 mL vials and 2 mL *Univials* and *Act-O-Vials*; 500 mg/vial in 1 mL, 4 mL, 8mL (with or without diluent) and 20 mL vials; 1 g/vial in 1 mL, 8 mL, 50 mL, & 1 g vials (with or without diluent), 8 mL *Act-O-Vials*; 2 g/vial with diluent; *Solu-Medrol*® (Pfizer); *A-Methapred*® (Hospira); generic; (Rx)

4-Methylpyrazole — see Fomepizole

METHYLTESTOSTERONE

(meth-ill-tess-toss-ter-ohn) **Android**®, **Methitest**®

ANDROGENIC/ANABOLIC

Prescriber Highlights

- Androgenic & anabolic agent that may be useful to suppress estrus, treat testosterone-responsive alopecia, & pseudopregnancy in dogs
- Use in cats is controversial as hepatotoxicity may be more prevalent
- Contraindicated in pregnancy or hepatic dysfunction
- Most serious adverse effect is hepatotoxicity

Uses/Indications

In female dogs, methyltestosterone may be useful for suppression of estrus, treating estrogen-dependent mammary tumors, pseudopregnancy, or certain hormonal-dependent alopecias. In male dogs, it may be useful for treating deficient libido and certain hormonal alopecias. In cats, methyltestosterone may be useful for certain hormonal-dependent alopecias and to increase libido in toms.

Because of the potential for abuse by humans, and potential toxicity (especially hepatotoxicity) in animals, use of methyltestosterone is somewhat controversial in veterinary medicine, particularly in racing Greyhounds and cats.

Pharmacology/Actions

Methyltestosterone is an androgen with anabolic effects. It has a methyl-group at the 17 position of the steroid nucleus of testosterone, resulting in better oral absorption and slower hepatic metabolism than testosterone. Androgens are required for both the development and maintenance of male sexual characteristics and function. The anabolic effects of methyltestosterone include stimulating erythropoiesis, enhancing nitrogen balance and protein anabolism (in the presence of sufficient protein and calories) and retention of potassium, sodium, and phosphorus.

Pharmacokinetics

Methyltestosterone is absorbed from the GI tract and oral mucosa. It undergoes less first pass metabolism than orally administered testosterone. In dogs, methyltestosterone is metabolized in the liver. Principle metabolites found in urine are glucuronidated forms (both conjugated and free) of methyltestosterone. Unlike in humans, sulfated forms are not a major metabolic component.

In humans, peak levels occur about 2 hours after oral dosing; elimination half-life is approximately 3 hours.

Contraindications/Precautions/Warnings

Methyltestosterone is contraindicated in patients with hepatic dysfunction and during pregnancy (see Reproductive Safety). It should be used with extreme caution in animals with heart failure. Prolonged use in young animals can cause premature epiphyseal closure.

Adverse Effects

Adverse effects in animals include: hepatotoxicity, virilization of females (clitoral hypertrophy), vaginal discharge, prostatic hyperplasia and increased aggression in males. Chronic dosing in dogs of 2–6 mg/kg/day for 27 weeks caused hepatotoxicity characterized by enlarged periportal hepatocytes, and hemosiderin in macrophages. Cats may be more susceptible to hepatic injury than are dogs.

Reproductive/Nursing Safety

Spermatogenesis suppression in males may occur with high dosage methyltestosterone secondary to a negative feedback mechanism. Methyltestosterone may suppress estrus in females (see Uses). After the drug is discontinued, normal reproductive function usually returns in both males and females.

Methyltestosterone is contraindicated during pregnancy. Dose-related genital masculinization of female fetuses is well described. In humans, the FDA categorizes this drug as category **X** for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*)

Overdosage/Acute Toxicity

Information on the acute toxicity of methyltestosterone is limited. Nausea and edema are the most likely effects of a single overdose. Consider liver function monitoring with large overdoses.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving methyltestosterone and may be of significance in veterinary patients:

- **CYCLOSPORINE:** Methyltestosterone may increase serum cyclosporine levels
- **INSULIN; ORAL ANTIDIABETIC AGENTS:** Methyltestosterone may decrease serum glucose levels
- **WARFARIN:** Methyltestosterone may increase anticoagulant effects

Laboratory Considerations

- Methyltestosterone or other androgens can decrease **thyroxine-binding globulin** concentrations. This can cause decreased serum levels of **total T₄** and increased resin uptake of T₄ and T₃. Clinically, this is unimportant, as free thyroid hormone concentrations are not affected.

Doses

■ DOGS/CATS:

- a) Dogs: For pinnal alopecia in male dogs: 1 mg/kg PO every other day, to a maximum dose of 30 mg has had some success. (Brignac and Bevier 1997)
- b) Dogs: For treatment of testosterone-responsive dermatosis: 1 mg/kg PO every other day, to a maximum dose of 30 mg. Once dog responds, then every 4–7 days. (Nelson and Elliott 2003a)
- c) Dogs: To suppress estrus in Greyhounds: 5 mg (total dose) once weekly or divided, two times a week. (Eilts 2005)
- d) Dogs: For estrus suppression: 25–50 mg (total dose) twice weekly PO. (Romagnoli 2003b)
- e) Dogs/Cats: For anti-estrogenic activity, development of male sexual characteristics (anatomical and behavioral), negative feedback on gonadotropin release from pituitary, and anabolic effects: 0.5 mg/kg PO once daily; dose may need to be adjusted, but should not exceed 1 mg/kg. (Label information; *Orandrone*®—Intervet UK. **Note:** This product has reportedly been withdrawn from the U.K. market.)

Monitoring

- Hepatic function (liver enzymes, icterus, anorexia/weight loss/vomiting)

Client Information

- Potential adverse effects include: liver toxicity, masculinization or vaginal discharge in females, prostate problems and aggression in males
- Contact veterinarian if any of the following occur: changes in behavior, anorexia/weight loss/vomiting, or signs of icterus

Chemistry/Synonyms

Methyltestosterone occurs as white or creamy-white, odorless, crystals or crystalline powder. It is slightly hygroscopic, practically insoluble in water, freely soluble in alcohol, and sparingly soluble in vegetable oils.

Methyltestosterone may also be known as NSC-9701 or by its chemical name, 17beta-Hydroxy-17alpha-methyladrost-4-ene-3-one, *Android*®, *Methitest*®, *Testred*® and *Virilon*®. A tradename for a veterinary product formerly available in the U.K. is *Orandrone*® (Intervet).

Storage/Stability

Unless otherwise specified by the manufacturer, methyltestosterone tablets or capsules should be stored below 40°C, preferably between 15°–30°C in well-closed containers.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See appendix for more information.

HUMAN-LABELED PRODUCTS:

Methyltestosterone Tablets: 10 mg, & 25 mg; *Methitest*® (Global), generic; (Rx, C-III)

Methyltestosterone Buccal Tablets: 10 mg; *Android*® (Valeant), generic; (Rx, C-III)

Methyltestosterone Capsules: 10 mg; *Testred*® (Valeant), *Virilon*® (Star); (Rx, C-III)

METOCLOPRAMIDE HCL

(met-oh-kloe-pra-mide) Reglan®

GI PROKINETIC AGENT**Prescriber Highlights**

- ▶ Stimulates upper GI motility & has antiemetic properties; more potent as an antiemetic than a prokinetic agent
- ▶ Contraindications: GI hemorrhage, obstruction or perforation, hypersensitivity
- ▶ Relatively contraindicated: Seizure disorders, pheochromocytoma
- ▶ Adverse Effects: DOGS: Changes in mentation & behavior, constipation; CATS: Signs of frenzied behavior or disorientation, constipation; HORSES: IV use, severe CNS effects, behavioral changes & abdominal pain; FOALS: Adverse effects less common

Uses/Indications

Metoclopramide has been used in veterinary species for both its GI stimulatory and antiemetic properties. It has been used clinically for gastric stasis disorders, gastroesophageal reflux, to allow intubation of the small intestine, as a general antiemetic (for parvovirus, uremic gastritis, etc.), and an antiemetic to prevent or treat chemotherapy-induced vomiting.

Pharmacology/Actions

The primary pharmacologic effects of metoclopramide are associated with the GI tract and the CNS. In the GI tract, metoclopramide stimulates motility of the upper GI without stimulating gastric, pancreatic or biliary secretions. While the exact mechanisms for these actions are unknown, it appears that metoclopramide sensitizes upper GI smooth muscle to the effects of acetylcholine. Intact vagal innervation is not necessary for enhanced motility, but anticholinergic drugs will negate metoclopramide's effects. Gastrointestinal effects seen include increased tone and amplitude of gastric contractions, relaxed pyloric sphincter, and increased duodenal and jejunal peristalsis. Gastric emptying and intestinal transit times can be significantly reduced. There is little or no effect on colon motility. Additionally, metoclopramide will increase lower esophageal sphincter pressure and prevent or reduce gastroesophageal reflux. The above actions evidently give metoclopramide its local antiemetic effects.

In the CNS, metoclopramide apparently antagonizes dopamine at the receptor sites. This action can explain its sedative, central anti-emetic (blocks dopamine in the chemo-receptor trigger zone), extrapyramidal, and prolactin secretion stimulation effects.

Pharmacokinetics

Metoclopramide is absorbed well after oral administration, but a significant first-pass effect in some human patients may reduce systemic bioavailability to 30%. There apparently is a great deal of interpatient variation with this effect. Bioavailability after intramuscular administration has been measured to be 74–96%. After oral dosing, peak plasma levels generally occur within 2 hours.

The drug is well distributed in the body and enters the CNS. Metoclopramide is only weakly bound to 13–22% of plasma proteins. The drug also crosses the placenta and enters the milk in concentrations approximately twice those of plasma.

Metoclopramide is primarily excreted in the urine in humans. Approximately 20–25% of the drug is excreted unchanged in the urine. The majority of the rest of the drug is metabolized to glucuronidated or sulfated conjugate forms and then excreted in the urine. Approximately 5% is excreted in the feces. The half-life of metoclopramide in the dog has been reported to be approximately 90 minutes.

Contraindications/Precautions/Warnings

Metoclopramide is contraindicated in patients with GI hemorrhage, obstruction or perforation, and in those hypersensitive to it. It is relatively contraindicated in patients with seizure disorders. In patients with pheochromocytoma, metoclopramide may induce a hypertensive crisis.

Adverse Effects

In dogs, the most common (although infrequent) adverse reactions seen are changes in mentation and behavior (motor restless and hyperactivity to drowsiness/depression). Cats may exhibit signs of frenzied behavior or disorientation. Both species can develop constipation while receiving this medication.

In adult horses, IV metoclopramide administration has been associated with the development of severe CNS effects. Alternating periods of sedation and excitement, behavioral changes and abdominal pain have been noted. These effects appear to be less common in foals.

Other adverse effects that have been reported in humans and are potentially plausible in animals include extrapyramidal effects, nausea, diarrhea, transient hypertension, and elevated prolactin levels.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Metoclopramide is excreted into milk and may concentrate at about twice the plasma level, but there does not appear to be significant risk to nursing offspring.

Overdosage/Acute Toxicity

The oral LD₅₀ doses of metoclopramide in mice, rats, and rabbits are 465 mg/kg, 760 mg/kg and 870 mg/kg, respectively. Because of the high dosages required for lethality, it is unlikely an oral overdose will cause death in a veterinary patient. Likely clinical signs of overdose include sedation, ataxia, agitation, extrapyramidal effects, nausea, vomiting, and constipation.

There is no specific antidotal therapy for metoclopramide intoxication. If an oral ingestion was recent, the stomach should be emptied using standard protocols. Anticholinergic agents (diphenhydramine 2.2 mg/kg IV, benztropine, etc.) that enter the CNS may be helpful in controlling extrapyramidal effects. Peritoneal dialysis or hemodialysis is not thought to be effective in enhancing the removal of the drug.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral metoclopramide and may be of significance in veterinary patients:

- **ANESTHETICS:** If metoclopramide is used concurrently IV, acute hypotension has been reported
- **ATROPINE** (and related anticholinergic compounds): May antagonize the GI motility effects of metoclopramide
- **CHOLINERGIC DRUGS** (e.g., **bethanechol**): May enhance metoclopramide's GI effects
- **CNS DEPRESSANTS** (e.g., **anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol**, etc.): Metoclopramide may enhance CNS depressant effects
- **CYCLOSPORINE:** Metoclopramide increase the rate and extent of GI absorption
- **OPIATE ANALGESICS:** May antagonize the GI motility effects of metoclopramide
- **MAO INHIBITORS** (including **amitraz** and potentially, **selegiline**): Could cause hypertension
- **PHENOTHIAZINES** (e.g., **acepromazine, chlorpromazine**, etc.) and **BUTYROPHENONES** (e.g., **droperidol, azaperone**): May potentiate the extrapyramidal effects of metoclopramide. The CNS effects of metoclopramide may be enhanced by other sedatives, tranquilizers, and narcotics.
- **TETRACYCLINES:** Metoclopramide increase the rate and extent of GI absorption

Doses

■ DOGS:

As an antiemetic:

- a) 0.1–0.4 mg/kg q6h PO, SC or IM; or 1–2 mg/kg/day as a continuous IV infusion (Washabau and Elie 1995)
- b) 0.22–0.55 mg/kg q8h parenterally; constant IV infusion of 1.1–2.2 mg/kg in 24 hours seems to be more effective than intermittent bolus therapy (Hall 2000)
- c) For bilious vomiting syndrome: 0.2–0.4 mg/kg PO once daily given late in the evening (Hall and Twedt 1988)
- d) To help prevent vomiting in patients with laryngeal paralysis and resultant tracheostomy: 0.05 mg/kg SC or slowly IV before small feedings (O'Brien, 1986)
- e) To treat vomiting associated with pancreatitis: 0.01–0.02 mg/kg/hr IV as a CRI or 0.1–0.5 mg/kg IM q8h (Waddell 2007c)

For disorders of gastric motility:

- a) 0.2–0.4 mg/kg PO three times daily given 30 minutes before meals (Hall and Twedt 1988)
- b) 0.2–0.5 mg/kg PO or SC q8h; give 30 minutes prior to meals and at bedtime for gastro-motility disorders and esophageal reflux (DeNovo 1986)
- c) 0.2–0.5 mg/kg PO q8h PO or parenterally (may be given as a constant rate IV infusion at 0.01–0.02 mg/kg/hr) (Hall and Washabau 2000)

To increase bladder contractility:

- a) 0.2–0.5 mg/kg PO q8h (Lane 2000)

■ CATS:

- a) 0.2–0.4 mg/kg PO, SC 3–4 times daily; or as a continuous IV infusion (1–2 mg/kg per day) (Trepanier 1999)
- b) 0.2–0.5 mg/kg q8h PO or parenterally (may be given as a constant rate IV infusion at 0.01–0.02 mg/kg/hr) (Hall and Washabau 2000)
- c) To increase bladder contractility: 0.2–0.5 mg/kg PO q8h (Lane 2000)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 0.2–1 mg/kg PO or SC q6–8h (Ivey and Morrissey 2000)
- b) Rabbits: To assist in removing gastric hairballs: 0.5 mg/kg PO once a day (up to three times a day) (Burke 1999)
- c) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 0.2–1 mg/kg PO, SC, IM q12h (Adamcak and Otten 2000)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

To stimulate the gastrointestinal tract:

- a) 0.04 mg/kg/hr as a CRI (Lester 2004)
- b) For reflux esophagitis: 0.02–0.1 mg/kg SC q4–12 hours; horses may be prone to the extrapyramidal neurologic side effects of metoclopramide. (Jones and Blikslager 2004)
- b) In foals: 0.02–0.1 mg/kg IM or IV 3–4 times a day (Clark and Becht 1987)

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- Contact veterinarian if animal develops clinical signs of involuntary movement of eyes, face, or limbs; or develops a rigid posture.

Chemistry/Synonyms

A derivative of para-aminobenzoic acid, metoclopramide HCl occurs as an odorless, white, crystalline powder with pK_as of 0.6 and 9.3. One gram is approximately soluble in 0.7 mL of water or 3 mL of alcohol. The injectable product has a pH of 3–6.5.

Metoclopramide HCl may also be known as: AHR-3070-C, DEL-1267, metoclopramidi hydrochloridum, and MK-745; many trade names are available.

Storage/Stability/Compatibility

Metoclopramide is photosensitive and must be stored in light resistant containers. All metoclopramide products should be stored at room temperature. Metoclopramide tablets should be kept in tight containers.

The injection is reportedly stable in solutions of a pH range of 2–9 and with the following IV solutions: D5W, 0.9% sodium chloride, D5-½ normal saline, Ringer's, and lactated Ringer's injection.

The following drugs have been stated to be physically **compatible** with metoclopramide for at least 24 hours: aminophylline, ascorbic acid, atropine sulfate, benztropine mesylate, chlorpromazine HCl, cimetidine HCl, clindamycin phosphate, cyclophosphamide, cytarabine, dexamethasone sodium phosphate, dimenhydrinate, diphenhydramine HCl, doxorubicin HCl, droperidol, fentanyl citrate, heparin sodium, hydrocortisone sodium phosphate, hydroxyzine HCl, insulin (regular), lidocaine HCl, magnesium sulfate, mannitol, meperidine HCl, methylprednisolone sodium succinate, morphine sulfate, multivitamin infusion (MVI), pentazocine lactate, potassium acetate/chloride/phosphate, prochlorperazine edisylate, TPN solution (25% dextrose with 4.25% *Travasol*® with or without electrolytes), verapamil, and vitamin B-complex with vitamin C.

Metoclopramide is reported to be physically **incompatible** when mixed with the following drugs: ampicillin sodium, calcium gluconate, cephalothin sodium, chloramphenicol sodium succinate, cisplatin, erythromycin lactobionate, methotrexate sodium, penicillin G potassium, sodium bicarbonate, and tetracycline. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

All doses expressed in terms of metoclopramide monohydrate.

Metoclopramide HCl Tablets: 5 mg & 10 mg; *Maxolon*® (SK-Beecham); *Reglan*® (Schwarz Pharma); generic; (Rx)

Metoclopramide HCl Syrup: 1 mg/mL in 480 mL and UD 10 mL; generic; (Rx) Metoclopramide HCl Injection: 5 mg/mL in 2 mL, 10 mL, 20 mL, 30 mL vials, & 2 mL amps, and preservative free in 2 mL, 10 mL, 30 mL vials; and 2 mL and 10 mL amps; *Reglan*® (Wyeth-Ayerst); *Octamide PFS*® (Adria); generic; (Rx)

METOPROLOL TARTRATE METOPROLOL SUCCINATE

(me-toe-pro-lole) Lopressor®, Toprol XL®

BETA-ADRENERGIC BLOCKER

Prescriber Highlights

- ▶ **Beta₁-blocker** used for supraventricular tachyarrhythmias, premature ventricular contractions (PVC's, VPC's), systemic hypertension, & treatment in cats with hypertrophic cardiomyopathy
- ▶ Probably safer to use than propranolol in animals with bronchoconstrictive disease
- ▶ **Contraindications:** Overt heart failure, hypersensitivity beta-blockers, greater than first-degree heart block, or sinus bradycardia
- ▶ **Caution:** Significant hepatic insufficiency, bronchospastic lung disease, CHF, hyperthyroidism (masks clinical signs, but may be useful for treatment), labile diabetics, & sinus node dysfunction
- ▶ **Adverse Effects:** Most common in geriatric animals or those that have acute decompensating heart disease, include: bradycardia, lethargy & depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, hypoglycemia, bronchoconstriction, syncope, & diarrhea
- ▶ Try to wean off drug gradually

Uses/Indications

Because metoprolol is relatively safe to use in animals with bronchospastic disease, it is often chosen over propranolol. It may be effective in supraventricular tachyarrhythmias, premature ventricular contractions (PVC's, VPC's), systemic hypertension, and treating cats with hypertrophic cardiomyopathy. There is increasing interest in using beta blockers in heart failure in dogs; one retrospective study showed increased survival times when dogs were given metoprolol, but definitive prospective, double-blinded studies have not been reported documenting the benefit (increased survival) of beta-blockers in dogs with heart failure.

Pharmacology/Actions

Metoprolol is a relatively specific beta₁-blocker and is sometimes characterized as a second generation beta blocker. At higher doses, this specificity may be lost and beta₂ blockade can occur. Metoprolol does not possess any intrinsic sympathomimetic activity like pindolol nor does it possess membrane-stabilizing activity like pindolol or propranolol. Cardiovascular effects secondary to metoprolol's negative inotropic and chronotropic actions include: decreased sinus heart rate, slowed AV conduction, diminished cardiac output at rest and during exercise, decreased myocardial oxygen demand, reduced blood pressure, and inhibition of isoproterenol-induced tachycardia.

Pharmacokinetics

Metoprolol tartrate is rapidly and nearly completely absorbed from the GI tract, but it has a relatively high first pass effect (50%) so systemic bioavailability is reduced. The drug has very low protein binding characteristics (5–15%) and is distributed well into most tissues. Metoprolol crosses the blood-brain barrier and CSF levels

are about 78% of those found in the serum. It crosses the placenta and levels in milk are higher (3-4X) than those found in plasma. Metoprolol is primarily biotransformed in the liver; unchanged drug and metabolites are then principally excreted in the urine. Reported half-lives in various species: Dogs: 1.6 hours; Cats: 1.3 hours; Humans 3–4 hours.

Contraindications/Precautions/Warnings

Metoprolol is contraindicated in patients with overt heart failure, hypersensitivity to this class of agents, greater than first-degree heart block, or sinus bradycardia. Non-specific beta-blockers are generally contraindicated in patients with CHF unless secondary to a tachyarrhythmia responsive to beta-blocker therapy. They are also relatively contraindicated in patients with bronchospastic lung disease.

Metoprolol should be used cautiously in patients with significant hepatic insufficiency or sinus node dysfunction.

Metoprolol (at high dosages) can mask the clinical signs associated with hypoglycemia. It can also cause hypoglycemia or hyperglycemia and, therefore, should be used cautiously in labile diabetic patients.

Metoprolol can mask the clinical signs associated with thyrotoxicosis, but it may be used clinically to treat the clinical signs associated with this condition.

Adverse Effects

It is reported that adverse effects most commonly occur in geriatric animals or those that have acute decompensating heart disease. Adverse effects considered clinically relevant include: bradycardia, lethargy and depression, impaired AV conduction, CHF or worsening of heart failure, hypotension, hypoglycemia, and bronchoconstriction (less so with beta1 specific drugs like metoprolol). Syncope and diarrhea have also been reported in canine patients with beta-blockers.

Exacerbation of clinical signs has been reported following abrupt cessation of beta-blockers in humans. It is recommended to withdraw therapy gradually in patients who have been receiving the drug chronically.

Reproductive/Nursing Safety

Safe use during pregnancy has not been established, but adverse effects to fetuses have apparently not been documented. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Metoprolol is excreted in milk in very small quantities and is unlikely to pose significant risk to nursing offspring.

Overdosage/Acute Toxicity

There is limited information available on metoprolol overdosage. Humans have apparently survived dosages of up to 5 grams. The most predominant clinical signs expected would be extensions of the drug's pharmacologic effects: hypotension, bradycardia, bronchospasm, cardiac failure, and, potentially, hypoglycemia.

There were 8 exposures to metoprolol reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 7 were dogs with 1 showing clinical signs and the remaining case was a cat that showed no clinical signs. Common findings in dogs recorded in decreasing frequency included lethargy and tachycardia.

If overdose is secondary to a recent oral ingestion, emptying the gut and charcoal administration may be considered. Use caution inducing emesis as coma and seizures may develop rapidly. Monitor: ECG, blood glucose, potassium, and, if possible, blood pressure.

Treatment of the cardiovascular effects is symptomatic. Use fluids and pressor agents to treat hypotension. Bradycardia may be treated with atropine. If atropine fails, isoproterenol, given cautiously, has been recommended. Use of a transvenous pacemaker may be necessary. Cardiac failure can be treated with a digitalis glycosides, diuretics, and oxygen. Glucagon (5–10 mg IV—Human dose) may increase heart rate and blood pressure and reduce the cardiodepressant effects of metoprolol.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving metoprolol and may be of significance in veterinary patients:

- **ANESTHETICS, GENERAL (with myocardial depressant effects):** Increased risk for heart failure and hypotension
- **CALCIUM-CHANNEL BLOCKERS** (e.g., **diltiazem, verapamil, amlodipine**): Concurrent use of beta-blockers with calcium channel blockers (or other negative inotropics) should be done with caution, particularly in patients with preexisting cardiomyopathy or CHF
- **DIGOXIN:** Use with metoprolol may increase negative effects on SA or AV node conduction
- **DIURETICS (thiazides, furosemide):** May increase hypotensive effect of metoprolol
- **HYDRALAZINE:** May increase the risks for pulmonary hypertension in uremic patients
- **QUINIDINE:** May increase metoprolol plasma concentrations
- **RESERPINE:** Potential for additive effects (hypotension, bradycardia)
- **SSRI ANTIDEPRESSANTS** (e.g., **fluoxetine, sertraline, paroxetine**): May increase metoprolol plasma concentrations
- **SYMPATHOMIMETICS** (**metaproterenol, terbutaline, beta-effects of epinephrine, phenylpropanolamine, etc.**): May have their actions blocked by metoprolol and they may, in turn, reduce the efficacy of atenolol

Doses

■ DOGS:

As an oral beta blocker:

- a) 5–50 mg (total dose) two to three times a day; initial dose should be low followed by individual dosage titration (Ware 1992)
- b) 0.2–0.4 mg/kg PO q12h and if all is well after two weeks, increase dose to 0.4 mg/kg twice daily. In dogs with chronic valvular disease, a third increment is made 2 weeks later to 0.6 mg/kg twice a day. (Rush and Freeman 2003)
- c) To decrease the incidence atrial fibrillation and flutter in dogs undergoing valve surgery: Using sustained release metoprolol (**Toprol-XR®**) at 0.4–1 mg/kg PO q24h administered before and as soon as feasible after surgery. (Orton 2006)

■ CATS:

As an oral beta blocker:

- a) 2–15 mg (total dose) PO q8h (Papich 1992), (Brovida 2002)

Monitoring

- Cardiac function, pulse rate, ECG if necessary, BP if indicated
- Toxicity (see Adverse Effects/Overdosage)

Client Information

- To be effective, the animal must receive all doses as prescribed
- Notify veterinarian if animal becomes lethargic or exercise intolerant, has shortness of breath or cough, or develops a change in behavior or attitude

Chemistry/Synonyms

A beta₁ specific adrenergic blocker, metoprolol tartrate occurs as a white, crystalline powder having a bitter taste. It is very soluble in water. Metoprolol succinate occurs as a white, crystalline powder and is freely soluble in water.

Metoprolol may also be known as: CGP-2175E; H-93/26, and metoprolol; many trade names are available.

Storage/Stability/Compatibility

Store all products protected from light. Store tablets in tight, light-resistant containers at room temperature. Avoid freezing the injection.

The injection is **compatible** with D5W and normal saline.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Metoprolol Tartrate Tablets: 25 mg, 50 mg & 100 mg; *Lopressor*® (Novartis); generic; (Rx)

Metoprolol Succinate Extended-Release Tablets (equivalent to metoprolol tartrate): 25 mg, 50 mg, 100 mg & 200 mg; *Toprol XL*® (Astra-Zeneca); (Rx)

Metoprolol Tartrate Injection: 1 mg/mL in 5 mL amps and *Carpject* sterile cartridge units; *Lopressor*® (Novartis); (Rx); generic; (Hospital); (Rx)

METRONIDAZOLE

(me-troe-ni-da-zole) Flagyl®

ANTIBIOTIC, ANTIPARASITIC

Prescriber Highlights

- ▶ **Injectable & oral antibacterial (anaerobes) & antiprotozoal agent**
- ▶ **Prohibited by the FDA for use in food animals**
- ▶ **Contraindications:** Hypersensitivity to it or nitroimidazole derivatives. Extreme caution: in severely debilitated, pregnant or nursing animals; hepatic dysfunction.
- ▶ **Adverse Effects:** Neurologic disorders, lethargy, weakness, neutropenias, hepatotoxicity, hematuria, anorexia, nausea, vomiting, & diarrhea
- ▶ **May be a teratogen, especially in early pregnancy**

Uses/Indications

Although there are no veterinary-approved metronidazole products, the drug has been used extensively in the treatment of *Giardia* in both dogs and cats. It is also used clinically in small animals for the treatment of other parasites (*Trichomonas* and *Balantidium coli*) as well as treating both enteric and systemic anaerobic infections.

In horses, metronidazole has been used clinically for the treatment of anaerobic infections.

Pharmacology/Actions

Metronidazole is bactericidal against susceptible bacteria. Its exact mechanism of action is not completely understood, but it is taken up by anaerobic organisms where it is reduced to an unidentified polar compound. It is believed that this compound is responsible

for the drug's antimicrobial activity by disrupting DNA and nucleic acid synthesis in the bacteria.

Metronidazole has activity against most obligate anaerobes including *Bacteroides* spp. (including *B. fragilis*), *Fusobacterium*, *Veillonella*, *Clostridium* spp., *Peptococcus*, and *Peptostreptococcus*. *Actinomyces* is frequently resistant to metronidazole.

Metronidazole is also trichomonacidal and amebicidal in action and acts as a direct amebicide. Its mechanism of action for its antiprotozoal activity is not understood. It has therapeutic activity against *Entamoeba histolytica*, *Trichomonas*, *Giardia*, and *Balantidium coli*. It acts primarily against the trophozoite forms of *Entamoeba* rather than encysted forms.

Finally, metronidazole has some inhibitive actions on cell-mediated immunity.

Pharmacokinetics

Metronidazole is relatively well absorbed after oral administration. The oral bioavailability in dogs is high, but interpatient variable, with ranges from 50–100% reported. The oral bioavailability of the drug in horses averages about 80% (range 57–100%). If given with food, absorption is enhanced in dogs, but delayed in humans. Peak levels occur about one hour after dosing.

Metronidazole is rather lipophilic and is rapidly and widely distributed after absorption. It is distributed to most body tissues and fluids, including bone, abscesses, the CNS, and seminal fluid. It is less than 20% bound to plasma proteins in humans.

Metronidazole is primarily metabolized in the liver via several pathways. Both the metabolites and unchanged drug are eliminated in the urine and feces. Elimination half-lives of metronidazole in patients with normal renal and hepatic function in various species are reported as: humans 6–8 hours, dogs 4–5 hours, and horses 2.9–4.3 hours.

Contraindications/Precautions/Warnings

Metronidazole is prohibited for use in food animals by the FDA.

Metronidazole is contraindicated in animals hypersensitive to the drug or nitroimidazole derivatives. It has been recommended not to use the drug in severely debilitated, pregnant or nursing animals. Metronidazole should be used with caution in animals with hepatic dysfunction. If the drug must be used in animals with significant liver impairment, consider using only 25–50% of the usual dose.

Adverse Effects

Adverse effects reported in dogs include neurologic disorders, lethargy, weakness, neutropenias, hepatotoxicity, hematuria, anorexia, nausea, vomiting, and diarrhea. Cats infrequently develop GI effects.

Neurologic toxicity in dogs may be manifested after acute high dosages or, more likely, with chronic moderate to high-dose therapy. Clinical signs reported are described below in the Overdosage section.

Metronidazole tablets have a sharp, metallic taste that animals find unpleasant. Placing in capsules or using compounded oral suspensions may alleviate the problem of dosing avoidance.

Reproductive/Nursing Safety

Metronidazole's potential for teratogenicity is somewhat controversial; some references state that it has been teratogenic in some laboratory animal studies, but others state that it has not. However, unless the benefits to the mother outweigh the risks to the fetus(es), it should not be used during pregnancy, particularly during the first 3 weeks of gestation. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in*

pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **C** (These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

Because of the potential for tumorigenicity, consider using alternative therapy or switching to milk replacer for nursing patients.

Overdosage/Acute Toxicity

Signs of intoxication associated with metronidazole in dogs and cats, include anorexia and/or vomiting, depression, mydriasis, nystagmus, ataxia, head-tilt, deficits of proprioception, joint knuckling, disorientation, tremors, seizures, bradycardia, rigidity and stiffness. These effects may be seen with acute overdoses or in some animals on chronic therapy when using "recommended" doses. Diazepam has been used successfully to decrease the CNS effects associated with metronidazole toxicity; see the Diazepam monograph or the reference by Evans, Levesque, et al for more information.

Acute overdoses should be handled by attempting to limit the absorption of the drug using standard protocols. Extreme caution should be used before attempting to induce vomiting in patients demonstrating CNS effects or aspiration may result. If acute toxicity is seen after chronic therapy, the drug should be discontinued and the patient treated supportively and symptomatically. Neurologic clinical signs may require several days before showing signs of resolving.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving metronidazole and may be of significance in veterinary patients:

- **ALCOHOL**: May induce a disulfiram-like (nausea, vomiting, cramps, etc.) reaction when given with metronidazole.
- **CIMETIDINE**: May decrease the metabolism of metronidazole and increase the likelihood of dose-related side effects occurring.
- **PHENOBARBITAL** or **PHENYTOIN**: May increase the metabolism of metronidazole, thereby decreasing blood levels.
- **WARFARIN**: Metronidazole may prolong the PT in patients receiving warfarin or other coumarin anticoagulants. Avoid concurrent use if possible; otherwise, intensify monitoring.

Laboratory Considerations

- Metronidazole can cause falsely decreased readings of **AST** (SGOT) and **ALT** (SGPT) when determined using methods measuring decreases in ultraviolet absorbance when NADH is reduced to NAD.

Doses

■ DOGS:

For treatment of Giardia:

- a) 15–25 mg/kg PO q12–24h daily for 5–7 days (Lappin 2006b)
- b) 44 mg/kg PO initially, then 22 mg/kg PO q8h for 5 days (Todd, Paul, and DiPietro 1985)
- c) 25–65 mg/kg PO once daily for 5 days (Longhofer 1988)
- d) 30–60 mg/kg PO once daily for 5–7 days (also for trichomoniasis) (Chiapella 1988)

For other protozoal infections:

- a) *Entamoeba histolytica* or *Pentatrichomas hominis*: 25 mg/kg PO q12h for 8 days (Lappin 2000)

For anaerobic infections:

- a) For anaerobic bacterial meningitis: 25–50 mg/kg PO q12h (Schunk 1988)
- b) For suppurative cholangitis: 25–30 mg/kg PO two times a day; may be used with chloramphenicol. Therapy may be necessary for 4–6 weeks (Cornelius and Bjorling 1988)
- c) For sepsis: 15 mg/kg IV q12h (Hardie 2000)
- d) 44 mg/kg PO q12h (Aronson and Aucoin 1989)
- e) For anaerobic sepsis: 10 mg/kg IV three times daily as a CRI (Tello 2003a)

For eliminating *Helicobacter gastritis* infections:

- a) Using triple therapy: Metronidazole 15.4 mg/kg q8h, amoxicillin 11 mg/kg q8h and bismuth subsalicylate (original *Pep-to-Bismol*®) 0.22 mL/kg PO q4–6h. Give each for 3 weeks. (Hall 2000)
- b) Using triple therapy: Metronidazole 33 mg/kg once daily, amoxicillin 11 mg/kg q12h and either sucralfate (0.25–0.5 grams q8h) or omeprazole 0.66 mg/kg once daily (Hall 2000)

For adjunctive therapy of plasmacytic/lymphocytic enteritis:

- a) 10 mg/kg PO three times daily for 2–4 weeks (Magne 1989)
- b) 10–30 mg/kg PO q8–24h for 2–4 weeks in refractory cases (Leib, Hay, and Roth 1989)

For inflammatory bowel disease:

- a) For ulcerative colitis in dogs refractory to other therapies (e.g., sulfasalazine, immunosuppressants, diet, etc.): 10–20 mg/kg PO twice daily–three times a day; may be beneficial in treating for 2–4 weeks those dogs with chronic colitis having unexplained diarrhea (Leib 2000).
- b) Starting dose of 10–15 mg/kg PO q12h and then tapered to the lowest effective dose. (Moore 2004)
- c) 10–15 mg/kg PO q8–12h; combine with prednisone to manage moderate to severe cases. (Marks 2007b)

For adjunctive therapy of hepatic encephalopathy:

- a) 20 mg/kg PO q8h (Hardy 1989)

■ CATS:

For treatment of Giardia:

- a) 15–25 mg/kg PO q12–24h daily for 5–7 days (Lappin 2006b)
- b) 25 mg/kg PO q12h for 7 days (Zoran 2007)

For other protozoal infections:

- a) *Entamoeba histolytica* or *Pentatrichomas hominis*: 25 mg/kg PO q12h for 8 days (Lappin 2000)

For treating *H. pylori*:

- a) Metronidazole 10–15 mg/kg PO two times a day; clarithromycin 7.5 mg/kg PO two times a day; amoxicillin 20 mg/kg PO twice daily for 14 days (Simpson 2003b)

For anaerobic infections:

- a) For sepsis: 15 mg/kg IV q12h (Hardie 2000)

For adjunctive therapy of GI conditions:

- For inflammatory bowel disease: Initially, metronidazole at 11–22 mg/kg PO twice daily with prednisolone (initially at 1.1–2.2 mg/kg twice daily for first 2–8 weeks until clinical signs improve). Usually at least several months of metronidazole therapy is needed. (Taboada 2000)
- Starting dose of 10–15 mg/kg PO q12h and then tapered to the lowest effective dose. (Moore 2004)
- For inflammatory bowel disease: With a change of diet to “hypoallergenic”, may give metronidazole at 62.5 mg (total dose) PO per cat once daily for 10–20 days. Resistant cats or those with severe disease are given immunosuppressive doses of prednisolone (1–2 mg/kg initially twice daily). (Gaschen 2006)
- 10–15 mg/kg PO q8–12h; combine with prednisone to manage moderate to severe cases. (Marks 2007b)
- For adjunctive therapy of hepatic lipidoses: 25–30 mg/kg PO twice daily for 2–3 weeks (unproven, but may be of benefit) (Cornelius and Bjorling 1988)
- For hepatic encephalopathy: 7.5 mg/kg PO q8–12h (Cornelius, Bartges et al. 2000)

■ FERRETS:

For eliminating *Helicobacter* gastritis infections:

- Using triple therapy: Metronidazole 22 mg/kg, amoxicillin 22 mg/kg and bismuth subsalicylate (original *Pepto-Bismol*®) 17.6 mg/kg PO. Give each 3 times daily for 3–4 weeks. (Hall 2000)

For susceptible infections:

- 10–30 mg/kg PO once to twice daily. Very bitter; mask flavor. (Williams 2000)

■ RABBITS, RODENTS, SMALL MAMMALS:

- Rabbits: For anaerobic infections: 20 mg/kg PO q12h for 3–5 days or 40 mg/kg PO once daily; 5 mg/kg slow IV q12h (Ivey and Morrissey 2000)
- Chinchillas: 10–40 mg/kg PO once daily as an antimicrobial; 50–60 mg/kg PO twice daily for 5 days as an antiparasiticide (*Giardia*) (Hayes 2000)
- Chinchillas, Gerbils, Guinea Pigs, Hamsters, Mice, Rats: 20–60 mg/kg PO q8–12h. Mice: 3.5 mg/mL in water for 5 days. Rats: 10–40 mg per rat PO once daily. Chinchillas, Guinea pigs: 10–40 mg/kg PO once daily. Gerbils, Hamsters: 7.5 mg/70–90 grams of body weight PO q8h. Add sucrose to improve palatability. (Adamcak and Otten 2000)

■ HORSES:

For susceptible anaerobic infections:

- 20–25 mg/kg PO q8–12h; for treatment of colitis due to *Clostridium* spp., may dose at 15 mg/kg PO q8h. Can also dose at same dosages rectally if unable to dose PO. Metronidazole is uncommonly associated with diarrhea and neurologic side effects. (Bentz 2007)
- 10–25 mg/kg PO 2–4 times a day (Chaffin 1999)
- Foals: 15 mg/kg PO or IV q6–12h (Brumbaugh 1999)
- Foals with *C. perfringens*: 10–15 mg/kg PO 3–4 times a day (dose depends on severity); if animal has an ileus and is intolerant of oral feeding give IV at 10 mg/kg IV 4 times a day (Slovics 2003a)
- For *L. intracellularis* infections: metronidazole 10–15 mg/kg PO q8–12h with either oxytetracycline (10–18 mg/kg via slow IV q24h) or chloramphenicol (44 mg/kg PO q6–8h). (Frazer 2007)

■ BIRDS:

For susceptible infections (anaerobes):

- 50 mg/kg PO once daily for 5 days (Bauck and Hoefer 1993)
- Ratites (not to be used for food): 20–25 mg/kg PO twice daily (Jenson 1998)

■ REPTILES:

- For anaerobic infections in most species: 150 mg/kg PO once; repeat in one week
For amoebae and flagellates in most species: 100–275 mg/kg PO once; repeat in 1–2 weeks.
In *Dryomarchon* spp., *Lampropeltis pyromelana*, and *L. zonata*: 40 mg/kg PO once; repeat in 2 weeks (Gauvin 1993)

Monitoring

- Clinical efficacy
- Adverse effects (clients should report any neurologic symptomatology)

Client Information

- Report any neurologic clinical signs to veterinarian (see Overdose section).

Chemistry/Synonyms

A synthetic, nitroimidazole antibacterial and antiprotozoal agent, metronidazole occurs as white to pale yellow crystalline powder or crystals with a pK_a of 2.6. It is sparingly soluble in water or alcohol. Metronidazole base is commercially available as tablets or solution for IV injection and metronidazole HCl is available as injectable powder for reconstitution. The hydrochloride is very soluble in water.

Metronidazole may also be known as: Bayer-5360, metronidazole, SC-32642, NSC-50364, RP-8823, and SC-10295; many trade names are available.

Storage/Stability/Compatibility

Metronidazole tablets and HCl powder for injection should be stored at temperatures less than 30°C and protected from light. The injection should be protected from light and freezing and stored at room temperature.

Specific recommendations on the reconstitution, dilution, and neutralization of metronidazole HCl powder for injection are detailed in the package insert of the drug and should be referred to if this product is used. Do not use aluminum hub needles to reconstitute or transfer this drug as a reddish-brown discoloration may result in the solution.

The following drugs and solutions are reportedly physically **compatible** with metronidazole ready-to-use solutions for injection: amikacin sulfate, aminophylline, carbenicillin disodium, ceftazolin sodium, cefotaxime sodium, cefoxitin sodium, cefuroxime sodium, cephalothin sodium, chloramphenicol sodium succinate, clindamycin phosphate, disopyramide phosphate, gentamicin sulfate, heparin sodium, hydrocortisone sodium succinate, hydromorphone HCl, magnesium sulfate, meperidine HCl, morphine sulfate, moxalactam disodium, multielectrolyte concentrate, multivitamins, netilmicin sulfate, penicillin G sodium, and tobramycin sulfate.

The following drugs and solutions are reportedly physically **incompatible** (or compatibility data conflicts) with metronidazole ready-to-use solutions for injection: aztreonam, cefamandole nate, and dopamine HCl.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

Metronidazole is prohibited for use in food animals by the FDA.

HUMAN-LABELED PRODUCTS:

Metronidazole Tablets: 250 mg & 500 mg; *Flagyl*® (Pharmacia); generic; (Rx)

Metronidazole Capsules: 375 mg; *Flagyl 375*® (Pharmacia); generic (Able); (Rx)

Metronidazole Extended-Release Tablets: 750 mg; *Flagyl ER*® (Pharmacia); generic (Able); (Rx)

Metronidazole HCl Powder for Injection: 500 mg/vial; *Flagyl*®IV (Pharmacia); (Rx)

Metronidazole Injection: 5 mg/mL in 100 mL vials and single-dose vials; *Flagyl*®I.V. (Pharmacia); generic; (B. Braun); (Rx)

Bismuth Subsalicylate, Metronidazole & Tetracycline HCl Combination Tablets & Capsules: 262.4 mg bismuth subsalicylate, 250 mg metronidazole; 500 mg tetracycline; *Helidac*® (Procter & Gamble); (Rx)

Lotions, gels, vaginal products and creams also available.

MEXILETINE HCL

(mex-ill-i-teen) Mexitil®

ORAL ANTIARRHYTHMIC

Prescriber Highlights

- ▶ Oral antiarrhythmic with similar effects as lidocaine; used for V tach, PVC's; often used with atenolol
- ▶ Extreme caution: Pre-existing 2nd or 3rd degree AV block (without pacemaker), or in patients with cardiogenic shock
- ▶ Caution: Severe congestive heart failure or acute myocardial infarction, hepatic function impairment, hypotension, intraventricular conduction abnormalities, sinus node function impairment, seizure disorder, or sensitivity to the drug
- ▶ Adverse Effects: GI distress, including vomiting (give with meals to alleviate); Potentially: CNS effects (trembling, unsteadiness, dizziness, depression), shortness of breath, PVC's & chest pain could occur; rarely (reported in humans): seizures, agranulocytosis, & thrombocytopenia
- ▶ Relatively expensive (compared to quinidine)
- ▶ Drug-drug; drug-lab interactions

Uses/Indications

Mexiletine may be useful to treat some ventricular arrhythmias, including PVC's and ventricular tachycardia in small animals. Ventricular tachycardias that have responded to lidocaine usually (but not always) respond to mexiletine as well. Mexiletine may have less cardiodepressant effects and appears to have fewer adverse effects than either procainamide or quinidine, but it is much more costly.

Mexiletine may be useful treating certain myopathies in dogs such as myotonia congenita (most studied in miniature schnauzers and Chow Chows) and myokymia in Jack Russell Terriers.

Pharmacology/Actions

Mexiletine is considered a class IB antiarrhythmic agent and is similar to lidocaine in its mechanism of antiarrhythmic activity. It inhibits the inward sodium current (fast sodium channel), thereby reducing the rate of rise of the action potential, Phase O. In the Purkinje fibers, automaticity is decreased, action potential is shortened and, to a lesser extent, effective refractory period is decreased. Usually conduction is unaffected, but may be slowed in patients with preexisting conduction abnormalities.

Pharmacokinetics

Mexiletine is relatively well absorbed from the gut and has a low first-pass effect. In humans, it is moderately bound to plasma proteins (60–75%), and is metabolized in the liver to inactive metabolites with an elimination half-life of about 10–12 hours. Half-lives may be significantly increased in patients with moderate to severe hepatic disease, or in those having severely reduced cardiac outputs. Half-lives may be slightly prolonged in patients with severe renal disease or after acute myocardial infarction.

Contraindications/Precautions/Warnings

Mexiletine should be used with extreme caution, if at all, in patients with pre-existing 2nd or 3rd degree AV block (without pacemaker), or with cardiogenic shock. It should be used only when the benefits of therapy outweigh the risks when the following medical conditions exist: severe congestive heart failure or acute myocardial infarction, hepatic function impairment, hypotension, intraventricular conduction abnormalities, sinus node function impairment, seizure disorder, or sensitivity to the drug.

Adverse Effects

The most likely adverse effect noted in animals is GI distress, including vomiting. Giving with meals may alleviate this. Potentially (reported in humans): CNS effects (trembling, unsteadiness, dizziness, depression), shortness of breath, PVC's and chest pain could occur. Rarely, seizures, agranulocytosis, and thrombocytopenia have been reported in humans.

Reproductive/Nursing Safety

Lab animal studies have not demonstrated teratogenicity. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Because mexiletine is secreted into maternal milk, it has been recommended to use milk replacer if the mother is receiving the drug.

Overdosage/Acute Toxicity

Toxicity associated with overdosage may be significant. Case reports in humans have noted that CNS signs always preceded cardiovascular signs. Treatment should consist of GI tract emptying protocols when indicated, acidification of the urine to enhance urinary excretion, and supportive therapy. Atropine may be useful if hypotension or bradycardia occur.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mexiletine and may be of significance in veterinary patients:

- **ANTACIDS, ALUMINUM-MAGNESIUM:** May slow the absorption of mexiletine
- **ATROPINE:** May reduce the rate of oral absorption
- **CIMETIDINE:** May increase or decrease mexiletine blood levels
- **GRISOFLUVIN:** May accelerate the metabolism of mexiletine
- **LIDOCAINE:** May cause additive adverse effects
- **METOCLOPRAMIDE:** May accelerate the absorption of mexiletine.
- **OPIATES:** May slow the absorption of mexiletine
- **PHENOBARBITAL, PRIMIDONE, PHENYTOIN:** May accelerate the metabolism of mexiletine
- **RIFAMPIN:** May accelerate the metabolism of mexiletine
- **THEOPHYLLINE (aminophylline):** Metabolism may be reduced by mexiletine, thereby leading to theophylline toxicity
- **URINARY ACIDIFYING DRUGS** (e.g., methionine, ammonium chloride, potassium phosphate, sodium phosphate): May accelerate the renal excretion of mexiletine
- **URINARY ALKALINIZING DRUGS** (e.g., citrates, bicarb, carbonic anhydrase inhibitors): May reduce the urinary excretion of mexiletine

Laboratory Considerations

- Some human patients (1–3%) have had **AST** values increase by as much as three times or more above the upper limit of normal. This is reportedly a transient effect and asymptomatic.

Doses

■ DOGS:

For treating or assisting in treatment of ventricular arrhythmias:

- a) 5–8 mg/kg PO q8h (Fox 2003a)
- b) 4–10 mg/kg PO q8h (Hogan 2004)
- c) For Boxers with ventricular arrhythmias: mexiletine at 5–7.5 mg/kg three times daily with sotalol at 1.5–3 mg/kg twice daily; was successful in 7/8 dogs treated in study, warrants further investigation. (Prosek, Estrada et al. 2006)
- d) 4–8 mg/kg PO q8h, combined with atenolol (0.5 mg/kg PO q12–24h) (Moise 2000)
- e) For familial arrhythmic cardiomyopathy of Boxers: 5–8 mg/kg PO q8h with atenolol at 12.5 mg (total dose) q12h (Meurs 2003)
- f) 5–6 mg/kg PO q8h; always give with food to avoid nausea. (Meurs 2006a)

For treating myotonia congenital (most studied in Chow Chows and miniature schnauzers) or myokymia in Jack Russell terriers:

- a) 8.3 mg/kg PO q8h (Lorenz 2007)

Monitoring

- In humans, therapeutic plasma concentrations are: 0.5–2 micrograms/mL; toxicity may be noted at therapeutic levels
- ECG
- Adverse effects

Client Information

- Give with food to reduce risk for vomiting or nausea
- Reinforce adherence to prescribed therapy.

Chemistry/Synonyms

A class IB antiarrhythmic, mexiletine HCl occurs as a white or almost white, odorless, crystalline powder. It is freely soluble in water.

Mexiletine may also be known as: Ko-1173, mexiletini hydrochloridum, *Mexilen*®, *Mexitil*®, *Mexitilen*®, *Myovek*®, and *Ritalmex*®.

Storage/Stability

Mexiletine capsules should be stored in tight containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Mexiletine Oral Capsules: 150 mg, 200 mg & 250 mg; *Mexitil*® (Boehringer Ingelheim); (Rx)

MIBOLERONE

(mye-boe-le-rone) *Cheque*® Drops

ANDROGEN; ANABOLIC

Prescriber Highlights

- Availability an issue; now a controlled substance in the USA
- Androgenic, anabolic, antigonadotropic used to suppress estrus, treat pseudocyesis (false pregnancy) or severe galactorrhea in dogs
- Contraindications: Perianal adenoma, perianal adenocarcinoma or other androgen-dependent neoplasias, pregnant or lactating bitches, ongoing or history of liver or kidney disease. The manufacturer also recommends not using the drug in Bedlington terriers.
- NOT for use in cats
- Adverse Effects: Prepuberal females: premature epiphyseal closure, clitoral enlargement, & vaginitis. Adult bitch: mild clitoral hypertrophy, vulvovaginitis, increased body odor, abnormal behavior, urinary incontinence, voice deepening, riding behavior, enhanced clinical signs of seborrhea oleosa, epiphora (tearing), hepatic changes (intranuclear hyaline bodies), & increased kidney weight (without pathology), hepatic dysfunction (rare)

Uses/Indications

Cheque® Drops was labeled as indicated “for estrous (heat) prevention in adult female dogs not intended primarily for breeding purposes.” In clinical trials it was 90% effective in suppressing estrus.

Although not approved, mibolerone at dosages of 50 micrograms per day will prevent estrus in the cat, but its use is generally not recommended because of the very narrow therapeutic index of the drug in this species (see the Adverse Effects and Overdosage sections for more information).

Pharmacology/Actions

Mibolerone acts by blocking the release of luteinizing hormone (LH) from the anterior pituitary via a negative feedback mechanism. Because of the lack of LH, follicles will develop to a certain point, but will not mature and hence no ovulation or corpus luteum development occurs. The net result is a suppression of the estrous cycle if the drug is given prior to (as much as 30 days) the onset of proestrus. After discontinuation of the drug, the next estrus may occur within 7–200 days (avg. 70 days).

Pharmacokinetics

Mibolerone is reported to be well absorbed from the intestine after oral administration and is rapidly metabolized in the liver to over 10 separate metabolites. Excretion is apparently equally divided between the urine and feces.

Contraindications/Precautions/Warnings

Mibolerone is contraindicated in female dogs with perianal adenoma, perianal adenocarcinoma or other androgen-dependent neoplasias. It is also contraindicated in patients with ongoing, or a history of, liver or kidney disease. The manufacturer recommends not using the drug in Bedlington Terriers.

Adverse Effects

Immature females (dogs) may be more prone to develop adverse reactions than more mature females. In prepubertal females, mibolerone can induce premature epiphyseal closure, clitoral enlargement, and vaginitis. Adverse effects that may be seen in the adult bitch include mild clitoral hypertrophy (may be partially reversible), vulvovaginitis, increased body odor, abnormal behavior, urinary incontinence, voice deepening, riding behavior, enhanced clinical signs of seborrhea oleosa, epiphora (tearing), hepatic changes (intracellular hyaline bodies), and increased kidney weight (without pathology). Although reported, overt hepatic dysfunction would be considered to occur rarely in dogs. With the exception of residual mild clitoral hypertrophy, adverse effects will generally resolve after discontinuation of therapy.

In the cat, dosages of 60 micrograms/day have caused hepatic dysfunction and 120 micrograms/day have caused death. Other adverse effects that have been noted in cats include clitoral hypertrophy, thyroid dysfunction, os clitorides formation, cervical dermis thickening, and pancreatic dysfunction.

Reproductive/Nursing Safety

Mibolerone should not be used in pregnant bitches; masculinization of the female fetuses will occur. Alterations seen may include: changes in vagina patency, multiple urethral openings in the vagina, a phallus-like structure instead of a clitoris, formation of testes-like structures, and fluid accumulation in the vagina and uterus. Because it may inhibit lactation, it should not be used in nursing bitches.

The manufacturer recommends discontinuing the product after 24 months of use. It should not be used to try to attempt to abbreviate an estrous period or in bitches prior to their first estrous period.

Overdosage/Acute Toxicity

Many toxicology studies have been performed in dogs. The drug did not cause death in doses up to 30,000 micrograms/kg/day when administered to beagles for 28 days. For a more detailed discussion of the toxicology of the drug, the reader is referred to the package insert for *Cheque® Drops*.

In the cat, dosages as low as 120 micrograms/day have resulted in fatalities.

Drug Interactions

Increased seizure activity has been reported in a dog after receiving mibolerone who was previously controlled on **phenytoin**. Mibolerone should generally not be used concurrently with **progestins** or **estrogens**.

Laboratory Considerations

■ Mibolerone has been reported to cause **thyroid** dysfunction in cats.

Doses

■ DOGS:

For suppression of estrus (treatment must begin at least 30 days prior to proestrus):

- a) Bitches weighing:
 - 0.5–11 kg: 30 micrograms (0.3 mL) PO per day
 - 12–22 kg: 60 micrograms (0.6 mL) PO per day
 - 23–45 kg: 120 micrograms (1.2 mL) PO per day
 - >45 kg: 180 micrograms (1.8 mL) PO per day
- German shepherds or German shepherd crosses: 180 micrograms (1.8 mL) PO per day; regardless of weight (Package Insert; *Cheque® Drops*—Upjohn)
- b) As above, but should dog come into estrus after receiving the drug for 30 or more days, stop drug and determine that the dog is not pregnant before resuming therapy. If owner compliance has been determined, increase dosage by 20–50%. (Woody 1988), (Burke 1985)

For pseudocyesis (false pregnancy):

- a) Use 10 times the dosage listed above for suppression of estrus PO once daily for 5 days (Barton and Wolf 1988)
- b) 16 micrograms/kg PO once daily for 5 days (Concannon 1986)

For cystic endometrial hyperplasia (CEH):

- a) 30 mcg/25lb. body weight PO daily during 6 months. (Fontbonne 2006)

For treatment of severe galactorrhea:

- a) 8–18 micrograms/kg PO once a day for 5 days. Once discontinued, prolactin may surge and galactorrhea resume. (Olson and Olson 1986)

■ CATS:

WARNING: Because of the very low margin of safety with this drug in cats, it cannot be recommended for use in this species.

Monitoring

- Clinical signs of estrus
- Liver function tests (baseline, annual, or as needed)
- Physical examination of genitalia

Client Information

- It must be stressed to owners that compliance with dosage and administration direction is crucial for this agent to be effective.

Chemistry/Synonyms

A non-progestational, androgenic, anabolic, antigonadotropic, 19-nor-steroid, mibolerone occurs as a white, crystalline solid.

Mibolerone may also be known as: dimethyl-nortestosterone, NSC-72260, and U-10997.

Storage/Stability

The manufacturer (Upjohn) states that the compound in *Cheque® Drops* is stable under ordinary conditions and temperatures.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Commercially prepared mibolerone preparations are apparently no longer being marketed. Mibolerone may be available from compounding pharmacies. Mibolerone is now categorized as a Class-III controlled substance in the USA.

HUMAN-LABELED PRODUCTS: None

MIDAZOLAM HCL

(mid-ay-zoe-lam) Versed®

PARENTERAL BENZODIAZEPINE**Prescriber Highlights**

- ▶ **Injectable benzodiazepine used primarily as a pre-op med; unlike diazepam may be given IM**
- ▶ **Contraindications: Hypersensitivity to benzodiazepines; acute narrow-angle glaucoma. Caution: Hepatic or renal disease, debilitated or geriatric patients, & those in coma, shock, or with significant respiratory depression.**
- ▶ **Adverse Effects: Potential for respiratory depression is of most concern**
- ▶ **Avoid intra-carotid injection**
- ▶ **Drug interactions**

Uses/Indications

In veterinary patients, midazolam is used principally as a premedicant for general anesthesia. Alone, it does not appear to provide predictable sedation in animals. Animals may become sedated or dysphoric and excited. Cats may be more prone to develop the “excited” effect more than dogs. When used in combination with other drugs (*i.e.*, opioids or ketamine), midazolam does provide more predictable sedation.

Midazolam may also be of benefit to treat status epilepticus when given either IV or IM (not rectally).

In humans, midazolam has been suggested for use as a premedicant before surgery, and as a conscious sedative when combined with potent analgesic/anesthetic drugs (*e.g.*, ketamine or fentanyl). In humans, midazolam reduces the incidences of “dreamlike” emergence reactions and increases in blood pressure and cardiac rate caused by ketamine.

When compared to the thiobarbiturate induction agents (*e.g.*, thiamylal, thiopental), midazolam has less cardiopulmonary depressant effects, is water-soluble, can be mixed with several other agents, and does not tend to accumulate in the body after repeated doses.

Pharmacology/Actions

Midazolam exhibits similar pharmacologic actions as other benzodiazepines. The subcortical levels (primarily limbic, thalamic, and hypothalamic), of the CNS are depressed by the benzodiazepines thus producing the anxiolytic, sedative, skeletal muscle relaxant, and anticonvulsant effects seen. The exact mechanism of action is unknown, but postulated mechanisms include: antagonism of serotonin, increased release of and/or facilitation of gamma-aminobutyric acid (GABA) activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. In all species studied, receptors are lacking in the white matter.

Midazolam's unique solubility characteristics (water soluble injection but lipid soluble at body pH) give it a very rapid onset of action after injection. When compared to diazepam, midazolam has approximately twice the affinity for benzodiazepine receptors, is nearly 3 times as potent, and has a faster onset of action and a shorter duration of effect.

Pharmacokinetics

Following IM injection, midazolam is rapidly and nearly completely (91%) absorbed. Midazolam is well absorbed after oral administration (no oral products are marketed), but because of a rapid first-pass effect, bioavailabilities suffer (31–72%). The onset of action following IV administration is very rapid due to the high lipophilicity of the agent. In humans, the loss of the lash reflex or counting occurs within 30–97 seconds of administration.

The drug is highly protein bound (94–97%) and rapidly crosses the blood-brain barrier. Because only unbound drug will cross into the CNS, changes in plasma protein concentrations and resultant protein binding may significantly alter the response to a given dose.

Midazolam is metabolized in the liver, principally by microsomal oxidation. An active metabolite (alpha-hydroxymidazolam) is formed, but because of its very short half-life and lower pharmacologic activity, it probably has negligible clinical effects. The serum half-life and duration of activity of midazolam in humans is considerably shorter than that of diazepam. Elimination half-lives in dogs average 77 minutes; in humans, approximately 2 hours (*vs.* approx. 30 hrs for diazepam).

In dogs, rectal bioavailability of midazolam is very low and this route is not useful clinically.

Contraindications/Precautions/Warnings

The manufacturer lists the following contraindications for use in humans: hypersensitivity to benzodiazepines, or acute narrow-angle glaucoma. Additionally, intra-carotid artery injections must be avoided.

Use cautiously in patients with hepatic or renal disease, and in debilitated or geriatric patients. Patients with congestive heart failure may eliminate the drug more slowly. The drug should be administered to patients in coma, shock, or with significant respiratory depression very cautiously.

When used alone, midazolam does not possess significant effects on cardiorespiratory function, but in combination with other agents, cardiorespiratory effects may be noted. Increased heart rate and blood pressure may be noted when used with ketamine. If this combination is used after an opioid has been administered, these effects may be diminished. If isoflurane will be used as the general anesthetic, use ketamine/midazolam with caution as bradycardia, hypotension and reduced cardiac output are possible.

Midazolam/opioid combinations can cause less cardiovascular depression, but greater respiratory depression, than acepromazine/opioid.

Midazolam and butorphanol used during isoflurane anesthesia can cause decreased blood pressure, heart rate and enhanced respiratory depression.

Adverse Effects

Few adverse effects have been reported in human patients receiving midazolam. Most frequently, effects on respiratory rate, cardiac rate and blood pressure have been reported. Respiratory depression has been reported in patients who have received narcotics or have COPD. The following adverse effects have been reported in more than 1%, but less than 5% of patients receiving midazolam: pain on injection, local irritation, headache, nausea, vomiting, and hiccups.

The principle concern in veterinary patients is the possibility of respiratory depression.

Reproductive/Nursing Safety

Although midazolam has not been demonstrated to cause fetal abnormalities, in humans, other benzodiazepines have been implicated in causing congenital abnormalities if administered during the first trimester of pregnancy. Infants born of mothers receiving large doses of benzodiazepines shortly before delivery have been reported to suffer from apnea, impaired metabolic response to cold stress, difficulty in feeding, hyperbilirubinemia, hypotonia, etc. Withdrawal symptoms have occurred in infants whose mothers chronically took benzodiazepines during pregnancy. The veterinary significance of these effects is unclear, but the use of these agents during the first trimester of pregnancy should only occur when the benefits clearly outweigh the risks associated with their use. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Midazolam is excreted in milk and may cause CNS effects in nursing neonates. Exercise caution when administering to a nursing mother.

Overdosage/Acute Toxicity

Very limited information is currently available. The IV LD₅₀ in mice has been reported to be 86 mg/kg. It is suggested that accidental overdoses be managed in a supportive manner, similar to diazepam. Flumazenil could be used to antagonize midazolam effects, but because of midazolam's short duration of effect and flumazenil's high cost, supportive therapy may be more suitable in all but the largest overdoses.

Drug Interactions

See the precautions noted above (Contraindications/Precautions) when using midazolam with other agents for preoperative use in small animals. The following drug interactions have either been reported or are theoretical in humans or animals receiving midazolam and may be of significance in veterinary patients:

- **ANESTHETICS, INHALATIONAL:** Midazolam may decrease the dosages required
- **AZOLE ANTIFUNGALS** (ketoconazole, itraconazole, fluconazole): May increase midazolam levels
- **CALCIUM CHANNEL BLOCKERS** (diltiazem, verapamil): May increase midazolam levels
- **CIMETIDINE:** May increase midazolam levels
- **CNS DEPRESSANTS, OTHER:** May increase the risk of respiratory depression
- **MACROLIDES** (erythromycin, clarithromycin): May increase midazolam levels
- **OPIATES:** May increase the hypnotic effects of midazolam and hypotension has been reported when used with meperidine.
- **PHENOBARBITAL:** May decrease peak levels and AUC of midazolam
- **RIFAMPIN:** May decrease peak levels and AUC of midazolam
- **THIOPENTAL:** Midazolam may decrease the dosages required

Doses

■ DOGS:

As a preoperative agent:

- a) 0.2–0.4 mg/kg IV or IM with an opioid such as hydromorphone (0.1 mg/kg IV or 0.2 mg/kg IM) (Day 2002)
- b) 0.1–0.3 mg/kg; may be used in combination with ketamine in a 50:50 mixture (volume/volume) at a dose of 1 mL/9.1 kg (1 mL/20 lb), this equates to a dose of 0.28 mg/kg of midazolam and 5.5 mg/kg of ketamine (Reed 2002)

- c) 0.1–0.5 mg/kg IV (Hellyer 2005b)

For status epilepticus:

- a) 0.25 mg/kg IV (Knipe 2006b)
- b) 0.2–0.4 mg/kg IV or IM (not per rectum); may repeat once. (Hopper 2006a)

■ CATS:

As a preoperative agent:

- a) 0.2–0.4 mg/kg IV or IM with an opioid such as hydromorphone (0.1 mg/kg IV or 0.2 mg/kg IM) (Day 2002)
- b) 0.05–0.5 mg/kg; a dose of 0.3 mg/kg being the most effective when mixed with ketamine to allow for intubation. May be used in combination with ketamine in a 50:50 mixture (volume/volume) at a dose of 1 mL/9.1 kg (1 mL/20 lb), this equates to a dose of 0.28 mg/kg of midazolam and 5.5 mg/kg of ketamine. (Reed 2002)
- c) 0.1–0.5 mg/kg IV (Hellyer 2005b)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: As a tranquilizer (to increase relaxation of lightly anesthetized animals and permit ET intubation): 1 mg/kg IV as needed (Huerkamp 1995)
- b) Rabbits: 1–2 mg/kg IM, IV. (Ivey and Morrissey 2000)
- c) Hamsters, Gerbils, Mice, Rats, Guinea pigs, Chinchillas: 1–2 mg/kg IM (Adamcak and Otten 2000)
- d) Rodents: 5 mg/kg IV (in combination with fentanyl/droperidol or fentanyl-fluanisone for neuroleptanesthesia) (Huerkamp 1995)

■ HORSES:

As a preoperative agent:

- a) 0.011–0.044 mg/kg IV (Mandsager 1988)

For seizure control in foals:

- a) 2–5 mg (total dose) for a 50kg foal given IV; rapid IV administration may result in apnea and hypotension. A CRI may be used at a dose of 1–3 mg/hour for a 50kg foal. (Bentz 2006b)
- b) 2–5 mg (total dose) for a 50kg foal given IV or IM; may be repeated to effect. (Toppin 2007)

■ BIRDS:

For adjunctive use (with an analgesic) for pain control:

- a) 1–2 mg/kg IM or IV (Clyde and Paul-Murphy 2000)

Monitoring

- Level of sedation
- Respiratory and cardiac signs

Client Information

- This agent should be used in an inpatient setting only or with direct professional supervision where cardiorespiratory support services are available.

Chemistry/Synonyms

Midazolam HCL is a benzodiazepine that occurs as a white or yellowish crystalline powder. Solubility in water is dependent upon pH. At a pH of 3.4 (approximately the pH of commercial injection), 10.3 mg are soluble in one mL of water.

Midazolam HCL may also be known as Ro-21-3981/003, Versed®, Dormicum®, Dormonid®, Fulsed®, Hypnovel®, Midaselect®, and Zolamid®.

Storage/Stability/Compatibility

It is recommended to store midazolam injection at room temperature (15°–30°C) and protected from light. After being frozen for 3 days and allowed to thaw at room temperature, the injectable product was physically stable. Midazolam is stable at a pH from 3–3.6.

Midazolam is reportedly physically **compatible** when mixed with the following products: D5W, normal saline, lactated Ringer's, atropine sulfate, fentanyl citrate, glycopyrrolate, hydroxyzine HCl, ketamine HCl, meperidine HCl, morphine sulfate, nalbuphine HCl, promethazine HCl, sufentanil citrate, and scopolamine HBr. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Midazolam HCl Injection: 1 mg (as HCl)/mL in 1 mL, 2 mL, 5 mL vials and *Carpusject* vials, 10 mL vials; 5 mg (as HCl)/mL in 1 mL, 2 mL, 5 mL vials and *Carpusject* vials, 10 mL vials, 2 mL syringes; generic; (Rx, C-IV)

Midazolam HCl Syrup: 2 mg/mL in 118 mL; generic; (Roxane); (Rx, C-IV)

MILBEMYCIN OXIME

(mil-beh-my-sin) Interceptor®, Sentinel®

MACROLIDE ANTIPARASITIC

For information on the combination product with lufenuron (Sentinel®), see the lufenuron monograph

Prescriber Highlights

- ▶ GABA inhibitor in invertebrates used for heartworm prophylaxis, microfilaricide, & treat demodicosis, etc.
- ▶ **Contraindications:** No absolute contraindications
- ▶ **Adverse Effects:** Animals with circulating microfilaria may develop a transient shock-like syndrome; at higher doses, neuro signs become more likely

Uses/Indications

Milbemycin tablets are labeled as a once-a-month heartworm preventative (*Dirofilaria immitis*) and for hookworm control (*Ancylostoma caninum*). It has activity against a variety of other parasites, including adult hookworms (*A. caninum*), adult roundworms (*T. canis*, *T. leonina*) and whipworms (*Trichuris vulpis*). In cats, milbemycin has been used successfully to prevent larval infection of *Dirofilaria immitis*.

Milbemycin, like ivermectin can be used for treatment of generalized demodicosis in dogs, but treatment can be significantly more expensive. It is likely safer to use in breeds susceptible to *mdr1* genetic mutation (Collies, Shelties, Australian shepherds, etc.) at the doses used for this indication, but neuro toxicity is possible. Older dogs, those that have had a long duration of disease prior to treatment, and dogs with pododemodicosis appear have a lower success rate with milbemycin treatment.

Pharmacology/Actions

Milbemycin is thought to act by disrupting the transmission of the neurotransmitter gamma amino butyric acid (GABA) in invertebrates.

Pharmacokinetics

No specific information was located. At labeled doses, milbemycin is considered effective for at least 45 days after infection by *D. immitis* larva.

Contraindications/Precautions/Warnings

Because some dogs with a high number of circulating microfilaria will develop a transient, shock-like syndrome after receiving milbemycin, the manufacturer recommends testing for preexisting heartworm infections.

The manufacturer states to not use the product (*Interceptor*®) in puppies less than 4 weeks of age or less than 2 lbs. of body weight or in kittens less than 6 weeks of age or less than 1.5 lbs. of body weight.

Adverse Effects

At labeled doses, adverse effects appear to be negligible in microfilaria-free dogs, including breeds susceptible to neurologic toxicity (see Overdosage below). At higher dosages (e.g., used for treating demodicosis) neurologic effects may be more likely particularly in dog breeds (Collies, etc.) with the genetic mutation that affects P-glycoprotein.

Eight week old puppies receiving 2.5 mg/kg (5X label) for 3 consecutive days showed no clinical signs after the first day, but after the second or third consecutive dose, showed some ataxia and trembling.

Reproductive/Nursing Safety

The manufacturer states that safety in breeding, pregnant, and lactating queens and breeding toms has not been established.

Studies in pregnant dogs at daily doses 3X those labeled showed no adverse effects to offspring or bitch.

Milbemycin does enter maternal milk; at standard doses, no adverse effects have been noted in nursing puppies.

Overdosage/Acute Toxicity

Beagles have tolerated a single oral dose of 200 mg/kg (200 times monthly rate). Rough-coated collies have tolerated doses of 10 mg/kg (20 times labeled) without adversity. Toxic doses can cause mydriasis, hypersalivation, lethargy, ataxia, pyrexia, seizures, coma and death. There is no specific antidotal treatment and supportive therapy is recommended.

Drug Interactions

The manufacturer states that the drug was used safely during testing in dogs receiving other frequently used veterinary products, including vaccines, anthelmintics, antibiotics, steroids, flea collars, shampoos and dips.

The following drug interactions have either been reported or are theoretical in humans or animals receiving GABA agonists and may be of significance in veterinary patients:

■ **BENZODIAZEPINES:** Effects may be potentiated by milbemycin; use together not advised in humans

Caution is advised if using other drugs that can inhibit **p-glycoprotein** particularly in those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc. "white feet"), unless tested "normal": Drugs and drug classes involved include:

- **AMIODARONE**
- **AZOLE ANTIFUNGALS** (e.g., *ketoconazole*)
- **CARVEDILOL**
- **CYCLOSPORINE**
- **DILTIAZEM**
- **ERYTHROMYCIN; CLARITHROMYCIN**
- **QUINIDINE**
- **SPIRONOLACTONE**
- **TAMOXIFEN**
- **VERAPAMIL**

Doses

■ DOGS:

For prophylaxis and treatment of dirofilariasis it is suggested to review the guidelines published by the American Heartworm Society at www.heartwormsociety.org for more information

As a parasiticide:

- a) For heartworm prophylaxis, control of adult hookworms (*A. caninum*), adult roundworms (*T. canis*, *T. leonina*) and whipworms (*Trichuris vulpis*) in dogs 4 weeks of age or older and at least 2 lbs. body weight: Minimum dosage is 0.5 mg/kg PO once a month. (Label information; *Interceptor*®—Novartis)
- b) 0.5–0.99 mg/kg PO once monthly (also controls hookworm, roundworm and whipworm infestations) (Calvert 1994)
- c) For control of fleas (prevents egg development), heartworm prophylaxis, control of adult hookworms (*A. caninum*), adult roundworms (*T. canis*, *T. leonina*) and whipworms (*Trichuris vulpis*) in dogs 4 weeks of age or older and at least 2 lbs. body weight: Minimum dosage is 0.5 mg/kg PO once a month. (Label directions; *Sentinel*®—Novartis) [**Note:** when used with nitenpyram (*Capstar*®) adult fleas are controlled as well]

For microfilaricide chemotherapy:

- a) In adulticide-pretreated dogs: Use preventative/prophylaxis dosage; repeat in 2 weeks if necessary. If heartworm transmission season has started, continue monthly prophylaxis. (Knight 1995)
- b) In adulticide-pretreated dogs: Approximately one month after melarsomine give milbemycin at 0.5 mg/kg PO. (Legendre and Toal 2000)

For treatment of generalized demodicosis:

- a) 0.5–2 mg/kg PO once daily. Higher dose seems to be more effective. (DeManuelle 2000)
- b) 2 mg/kg PO daily for 30 days past two consecutive negative skin scrapings obtained 4–6 weeks apart. At doses no higher than 2 mg/kg/day, breeds at high risk for toxicity (Collies, Shelties, Australian shepherds, etc.) are apparently tolerant to milbemycin. (Torres 2007b)
- c) 1 mg/kg PO twice daily for at least 3 months (White 2000)

For treatment of cheyletiellosis:

- a) 2 mg/kg PO every 7 days for 3 doses (White 2000)

For treatment of scabies:

- a) 2 mg/kg PO every 7 days for 3 doses or 0.75 mg/kg once daily for 30 days (White 2000)

■ CATS:

For prevention of heartworm; treat adult hookworm and adult roundworms:

- a) 2 mg/kg PO once monthly (Label directions; *Interceptor*® *Flavor Tabs for Cats*—Novartis)

■ REPTILES:

For nematodes:

- a) 0.5–1 mg/kg PO; repeat in 2 weeks. If 14 days after second dose, fecal is positive a third dose is given and the cycle continued until parasites are cleared. Milbemycin appears to be safe in chelonians (unlike ivermectin). (de la Navarre 2003b)

Client Information

- Review importance of compliance with therapy and to be certain that the dose was consumed.

Chemistry/Synonyms

Milbemycin oxime consists of approximately 80% of the A₄ derivatives and 20% of the A₃ derivatives of 5-didehydromilbemycin. Milbemycin is considered to be a macrolide antibiotic structurally.

Milbemycin may also be known as CGA-179246, *Interceptor*® and *Sentinel*®.

Storage/Stability

Store milbemycin oxime tablets at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Milbemycin Oxime Oral Tablets: 2.3 mg (brown, 2–10 lbs), 5.75 mg (green, 11–25 lbs), 11.5 mg (yellow, 26–50 lbs), 23 mg (white, 51–100 lbs), dogs >100 lbs are provided the appropriate combination of tablets; *Interceptor*® *Flavor Tabs*; (Novartis); (Rx). Approved for use in dogs and puppies >4 weeks of age and 2 lbs or greater.

Milbemycin Oxime Oral Tablets: 5.75 mg (1.5–6 lbs), 11.5 mg (6.1–12 lbs), 23 mg (white, 12.1–25 lbs); *Interceptor*® *Flavor Tabs*; (Novartis); (Rx). Approved for cats and kittens >6 wks old and >1.5 lbs.

Milbemycin/Lufenuron Oral Tablets (with Nitenpyram Oral Tablets in the combination flea management system) for Dogs:

For dogs 2–10 lb: 46 mg milbemycin/lufenuron, (11.4 mg nitenpyram)

For dogs 11–25 lb: 115 mg milbemycin/lufenuron, (11.4 mg nitenpyram)

For dogs 26–50 lb: 230 mg milbemycin/lufenuron, (57 mg nitenpyram)

For dogs 51–100 lb: 460 mg milbemycin/lufenuron, (57 mg nitenpyram)

For dogs 100–125 lb: (appropriate number supplied) milbemycin/lufenuron, (57 mg nitenpyram)

Sentinel® *Flavor Tabs* & *Sentinel*® *Flavor Tabs with Capstar*® *Flea Management System* (Novartis); (Rx). Approved for use in dogs and puppies 4 weeks of age or older.

There is also a milbemycin 0.1% otic solution (*Milbemite*®) available.

HUMAN-LABELED PRODUCTS: None

Milk Thistle—see Silymarin

MINERAL OIL

White Petrolatum

LUBRICANT LAXATIVE

Prescriber Highlights

- ▶ Lubricant laxative
- ▶ **Cautions:** Debilitated or pregnant patients, & patients with hiatal hernia, dysphagia, esophageal or gastric retention
- ▶ Use caution when administering by tube to avoid aspiration
- ▶ **Adverse Effects:** Lipid pneumonitis if aspirated; granulomatous reactions in liver etc. if significant amounts are absorbed from gut; oil leakage from the anus; long-term use may lead to decreased absorption of fat-soluble vitamins (A, D, E, & K)
- ▶ Drug interactions

Uses/Indications

Mineral oil is commonly used in horses to treat constipation and fecal impactions. It is also employed as a laxative in other species as well, but used less frequently. Mineral oil has been administered after ingesting lipid-soluble toxins (e.g., kerosene, metaldehyde) to retard the absorption of these toxins through its laxative and solubility properties.

Petrolatum containing products (e.g., *Felaxin*®, *Laxatone*®, *Kat-A-Lax*®, etc.) may be used in dogs and cats as a laxative or to prevent/reduce “hair-balls” in cats.

Pharmacology/Actions

Mineral oil and petrolatum act as laxatives by lubricating fecal material and the intestinal mucosa. They also reduce reabsorption of water from the GI tract, thereby increasing fecal bulk and decreasing intestinal transit time.

Pharmacokinetics

It has been reported that after oral administration, emulsions of mineral oil may be up to 60% absorbed, but most reports state that mineral oil preparations are only minimally absorbed from the gut.

Contraindications/Precautions/Warnings

No specific contraindications were noted with regard to veterinary patients. In humans, mineral oil (orally administered) is considered contraindicated in patients less than 6 yrs. old, debilitated or pregnant patients, and patients with hiatal hernia, dysphagia, esophageal or gastric retention. Use caution when administering by tube to avoid aspiration, especially in debilitated or recalcitrant animals. To avoid aspiration in small animals, orally administered mineral oil should not be attempted when there is an increased risk of vomiting, regurgitation, or other preexisting swallowing difficulty. Many clinicians believe that mineral oil should not be administered orally to small animals due to the risk for aspiration and, if used as a laxative, should be administered rectally.

Adverse Effects

When used on a short-term basis and at recommended doses, mineral oil or petrolatum should cause minimal adverse effects. The most serious effect that could be encountered is aspiration of the oil with resultant lipid pneumonitis; prevent this by using the drug only in appropriate cases, when “tubing”, ascertain that

the tube is in the stomach, and administer the oil at a reasonable rate.

Granulomatous reactions have occurred in the liver, spleen and mesenteric lymph nodes when significant quantities of mineral oil are absorbed from the gut. Oil leakage from the anus may occur and be of concern in animals with rectal lesions or in house pets. Long-term administration of mineral oil/petrolatum may lead to decreased absorption of fat-soluble vitamins (A, D, E, and K). No reports were found documenting clinically significant hypovitaminosis in cats receiving long-term petrolatum therapy, however.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Oral mineral oil should be safe to use during nursing.

Overdosage/Acute Toxicity

No specific information was located regarding overdoses of mineral oil; but it would be expected that with the exception of aspiration, the effects would be self-limiting. See adverse effects section for more information.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mineral oil and may be of significance in veterinary patients:

- **DOCUSATE:** Theoretically, mineral oil should not be given with docusate (DSS) as enhanced absorption of the mineral oil could occur. However, this does not appear to be of significant clinical concern with large animals.
- **VITAMINS A, D, E, K:** Chronic administration of mineral oil may affect Vitamin K and other fat-soluble vitamin absorption. It has been recommended to administer mineral oil products between meals to minimize this problem.

Doses

■ DOGS:

- As a laxative:
 - a) 2–60 mL PO (Jenkins 1988), (Kirk 1989)
 - b) 5–30 mL PO (Davis 1985a)
 - c) 5–25 mL PO (Burrows 1986)

■ CATS:

- As a laxative (See specific label directions for “Cat Laxative” Products):
 - a) 2–10 mL PO (Jenkins 1988), (Kirk 1989)
 - b) 2–6 mL PO (Davis 1985a)
 - c) 5 mL per day with food (Sherding 1989)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: As a laxative/remove hairballs: Using feline laxative product: 1–2 mL/day for 3–5 days (Ivey and Morrissey 2000)

■ CATTLE:

Note: Administer via stomach tube.

- As a laxative:
 - a) 1–4 liters (Howard 1986)
 - b) Adults: 0.5–2 liters; Calves: 60–120 mL (Jenkins 1988)
- For adjunctive treatment of metaldehyde poisoning:
 - a) 8 mL/kg; may be used with a saline cathartic (Smith 1986)
- For adjunctive treatment of nitrate poisoning:
 - a) 1 liter per 400 kg body weight (Ruhr and Osweiler 1986)

■ HORSES:

As a laxative (Administer via stomach tube):

- For large colon impactions: 2–4 quarts q12–24 hours, may take up to 5 gallons. Mix 1–2 quarts of warm water with the oil to ease administration and give more fluid to the horse. Pumping in at a moderate speed is desirable over gravity flow. (Sellers and Lowe 1987)
- Adults: 2–4 liters, may be repeated daily; Foals: 240 mL (Clark and Becht 1987)
- Adults: 0.5–2 liters; Foals: 60–120 mL (Jenkins 1988)

■ SWINE:

- As a laxative: 50–100 mL; administer via stomach tube (Howard 1986)

■ SHEEP & GOATS:

- As a laxative: 100–500 mL; administer via stomach tube (Howard 1986)

■ BIRDS:

Use as a laxative and to aid in the removal of lead from the gizzard:

- 1–3 drops per 30 grams of body weight or 5 mL/kg PO once. Repeat as necessary. Give via tube or slowly to avoid aspiration. (Clubb 1986)

Monitoring

- Clinical efficacy
- If possibility of aspiration: auscultate, radiograph if necessary

Client Information

- Follow veterinarian's instructions or label directions for "cat laxative" products.
- Do not increase dosage or prolong treatment beyond veterinarian's recommendations.

Chemistry/Synonyms

Mineral oil, also known as liquid petrolatum, liquid paraffin or white mineral oil occurs as a tasteless, odorless (when cold), transparent, colorless, oily liquid that is insoluble in both water and alcohol. It is a mixture of complex hydrocarbons and is derived from crude petroleum. For pharmaceutical purposes, heavy mineral oil is recommended over light mineral oil, as it is believed to have a lesser tendency to be absorbed in the gut or aspirated after oral administration.

White petrolatum, also known as white petroleum jelly or white soft paraffin, occurs as a white or faintly yellow unctuous mass. It is insoluble in water and almost insoluble in alcohol. White petrolatum differs from petrolatum only in that it is further refined to remove more of the yellow color.

Mineral oil may also be known as: liquid paraffin, 905 (mineral hydrocarbons), dickflüssiges paraffin, heavy liquid petrolatum, huile de vaseline epaisse, liquid petrolatum, oleum petrolei, oleum vaselini, paraffinum liquidum, paraffinum subliquidum, vaselinol, vaselinum liquidum, and white mineral oil; many trade names are available.

Storage/Stability

Petrolatum products should be stored at temperatures less than 30°C.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Mineral oil products have not been formally approved for use in food animals. These products and preparations are available without a prescription (OTC).

Petrolatum Oral Preparations

Liquid Mineral Oil: available in gallons or 55 gallon drums.

Cat "Laxative" Products: Products may vary in actual composition; some contain liquid petrolatum in place of white petrolatum and may have various flavors (tuna, caviar, malt, etc.). Trade names include (not necessarily complete): *Laxatone*®, *Laxa-Stat*® (Evsco and Tomlyn Health); *Vedalax*® (Vedco); *Cat Lax*® (Pharmaderm); *Vetscription*® *Hairball Remedy* (Sergeant's); *Hairball Preparation*® (Vet Solutions); *Hartz*® *Health Measures Hairball Remedy* (Hartz Mountain); *Petromalt*® (Virbac); *Petrotone*® (Butler); *Felilax*® (Vetus)

HUMAN-LABELED PRODUCTS:

Mineral Oil Liquid: in 180 mL and 473 mL; generic; (OTC)

Mineral Oil Emulsions:

There are several products available that are emulsions of mineral oil and may be more palatable for oral administration. Because of expense and with no increase in efficacy, they are used only in small animals. They may be dosed as described above, factoring in the actual percentage of mineral oil in the preparation used. Trade names include: *Kondremul*® *Plain* (Heritage Consumer Prod); (OTC) Various generic products are available.

MINOCYCLINE HCL

(mi-noe-sye-kleen) Minocin®, Dynacin®

TETRACYCLINE ANTIBIOTIC**Prescriber Highlights**

- Oral & parenteral tetracycline antibiotic
- Contraindications: Hypersensitivity to it
- Less likely to cause bone & teeth abnormalities than other tetracyclines, but avoid use in pregnancy & young animals
- May be used in patients with renal insufficiency
- Adverse Effects are most commonly GI-related
- Drug-drug; drug-lab interactions

Uses/Indications

Minocycline may be useful for treating Brucellosis (in combination with aminoglycosides), Lyme disease, and certain nosocomial infections where other more commonly used drugs are ineffective. It has been investigated as adjunctive therapy for treating hemangiosarcomas, but early results have been disappointing.

Pharmacology/Actions

Tetracyclines generally act as bacteriostatic antibiotics and inhibit protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, thereby preventing binding to those ribosomes of aminoacyl transfer-RNA. Tetracyclines are believed to reversibly bind to 50S ribosomes and additionally alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can also inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most mycoplasma, spirochetes (including the Lyme disease organism), Chlamydia, and Rickettsia. Against gram-positive bacteria, the tetracyclines have activity against some strains of staphylococci and streptococci, but resistance of these organisms is increasing. Gram-positive bacteria that are usually covered by tetracyclines, include *Actinomyces* spp., *Bacillus anthracis*, *Clostridium perfringens* and tetani, *Listeria monocytogenes*, and *Nocardia*. Among gram-negative bacteria that tetracyclines usually have *in vitro* and *in vivo* activity include *Bordetella* spp., *Brucella*, *Bartonella*, *Haemophilus* spp., *Pasturella multocida*, *Shigella*, and *Yersinia pestis*. Many or most strains of *E. coli*, *Klebsiella*, *Bacteroides*, *Enterobacter*, *Proteus*, and *Pseudomonas aeruginosa* are resistant to the tetracyclines.

Pharmacokinetics

Minocycline is well absorbed after oral absorption regardless of the presence of food. Minocycline is highly lipid soluble and is distributed widely throughout the body. Therapeutic levels can be found in the CSF (whether meninges are inflamed or not), prostate, saliva, and eye. Minocycline is extensively metabolized in the liver and primarily excreted as inactive metabolites in the feces and urine. Less than 20% is excreted unchanged in the urine. The half-life in dogs is about 7 hours.

Contraindications/Precautions/Warnings

Minocycline should be considered contraindicated in patients hypersensitive to tetracyclines, those that are pregnant or nursing, or in animals less than 6 months old. Minocycline is considered to be less likely to cause these abnormalities than other more water-soluble tetracyclines (e.g., tetracycline, oxytetracycline). Unlike either oxytetracycline or tetracycline, minocycline can be used in patients with moderate renal insufficiency without dosage adjustment. Oliguric renal failure may require dosage adjustment.

Adverse Effects

The most commonly reported side effects of oral minocycline therapy in dogs and cats are nausea and vomiting. To alleviate these effects, the drug could be given with food without clinically significant reductions in drug absorption. Dental or bone staining can occur when minocycline exposure occurs in utero or in early life. More rarely, increases in hepatic enzymes and ototoxicity are possible.

IV injections of minocycline in dogs have caused urticaria, shivering, hypotension, dyspnea, cardiac arrhythmias, and shock when given rapidly. Give IV slowly.

Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of non-susceptible bacteria or fungi.

In humans, minocycline (or other tetracyclines) has also been associated with photosensitivity reactions and, rarely, hepatotoxicity or blood dyscrasias. CNS effects (dizziness, lightheadedness) have been reported in people taking minocycline. A blue-gray pigmentation of skin and mucous membranes may occur.

Reproductive/Nursing Safety

Because tetracyclines can retard fetal skeletal development and discolor deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Minocycline has been shown to impair fertility in male rats. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Tetracyclines are excreted in milk. Milk:plasma ratios vary between 0.25 and 1.5. While minocycline probably has less effect on teeth and bones than other tetracyclines, its use should be avoided during nursing.

Overdosage/Acute Toxicity

Minocycline oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Although it is less vulnerable to chelation with cations than other tetracyclines, oral administration of divalent or trivalent cation antacids may bind some of the drug and reduce GI distress. Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving minocycline and may be of significance in veterinary patients:

- **ANTACIDS, ORAL:** When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations. Oral antacids, saline cathartics, or other GI products containing aluminum, calcium, magnesium, zinc, or bismuth cations are most commonly associated with this interaction. Minocycline has a relatively low affinity for divalent or trivalent cations, but it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing product.
- **BISMUTH SUBSALICYLATE, KAOLIN, PECTIN:** May reduce absorption
- **IRON, ORAL:** Oral iron products are associated with decreased tetracycline absorption, and administration of iron salts should preferably be given 3 hours before or 2 hours after the tetracycline dose.
- **ISOTRETINOIN:** When used with minocycline may increase the risk for nervous system effects
- **PENICILLINS:** Bacteriostatic drugs, like the tetracyclines, may interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides. There is a fair amount of controversy regarding the actual clinical significance of this interaction, however.
- **WARFARIN:** Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant therapy may need dosage adjustment.

Laboratory Considerations

- Tetracyclines reportedly can cause false-positive **urine glucose** results if using the cupric sulfate method of determination (Benedict's reagent, *Clinitest*®), but this may be the result of ascorbic acid that is found in some parenteral formulations of tetracyclines.
- Tetracyclines reportedly have caused false-negative results in determining **urine glucose** when using the glucose oxidase method (*Clinistix*®, *Tes-Tape*®).

Doses

■ DOGS:

- a) For susceptible soft tissue and urinary tract infections: 5–12 mg/kg PO or IV q12h for 7–14 days. (Greene, Hartmann et al. 2006)
- b) For Brucellosis: Gentamicin 5 mg/kg SC once daily (q24h) for 7 days; 2-courses of treatment, treating on weeks one and four; plus Minocycline at 25 mg/kg PO once daily (q24h) for 4 weeks. Eventually, doxycycline can be substituted for minocycline at the same dosage to lower cost. Infected animals may need to be treated for two or more 4-week courses. Sequential antibody tests at 3 to 6 monthly intervals are recommended to monitor treatment. Monitor renal function secondary to gentamicin therapy. (Hartmann and Greene 2005)

- c) For adjunctive treatment of Nocardiosis, Actinomycosis: 5–25 mg/kg PO, IV q12h (Lemarie 2003a)
- d) For Brucellosis in animals that are housed singly and neutered: Minocycline at 25 mg/kg PO once daily for 14 days with dihydrostreptomycin (**Note:** not currently available in the USA) at 5 mg/kg IM twice daily for 7 days. (Root Kustritz 2007)

■ CATS:

- a) For hemotropic mycoplasmosis: 6–11 mg/kg PO q12h for 21 days. (Greene, Hartmann et al. 2006)
- b) For adjunctive treatment atypical mycobacterial dermal infections: 5–12.5 mg/kg PO, IV q12h (Hnilica 2003a)
- c) For adjunctive treatment of Nocardiosis, Actinomycosis: 5–25 mg/kg PO, IV q12h (Lemarie 2003a)

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- Oral minocycline products may be administered without regard to feeding. Milk or other dairy products do not significantly alter the amount of minocycline absorbed.
- Give as prescribed for as long as veterinarian recommends even if animal appears well.

Chemistry/Synonyms

A semisynthetic tetracycline, minocycline HCl occurs as a yellow, crystalline powder. It is soluble in water and slightly soluble in alcohol.

Minocycline may also be known as: minocyclini hydrochloridum, *Asolmicina*®, *Cyclimycin*®, *Cyclomin*®, *Dermirex*®, *Meibi*®, *Minogal*®, and *Minox*®; many other trade names are available.

Storage/Stability/Compatibility

Store the oral preparations at room temperature in tight containers. Do not freeze the oral suspension. The injectable should be stored at room temperature and protected from light. After reconstituting with sterile water for injection, solutions with a concentration of 20 mg/mL are stable for 24 hours at room temperature.

While minocycline is **compatible** with the usual intravenous fluids (including Ringer's and lactated Ringer's) do not add any other calcium containing fluid as precipitation could result.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Minocycline HCl Tablets: 50 mg, 75 mg, 100 mg; Extended-Release: 45 mg, 90 mg & 135 mg; Minocycline HCl (Par); *Dynacin*® (Medicis); *Myrac*® (Glades); *Solodyn*® (Medicis); (Rx)

Minocycline HCl Capsules: 50 mg, 75 mg, 100 mg; *Minocin*® (Lederle); *Dynacin*® (Medicis); generic; (Rx)

Minocycline HCl Oral Suspension: 50 mg/5 mL in 60 mL; *Minocin*® (Lederle); (Rx)

Minocycline HCl Powder for Injection cryodesiccated: 100 mg per vial; *Minocin*® (Triax); (Rx)

Minocycline HCl Microspheres, Sustained-Release: 1 mg; *Arestin*® (Cord Logistics); (Rx)

MIRTAZAPINE

(mir-taz-ah-peen) Remeron®

TETRACYCLIC ANTIDEPRESSANT; 5-HT₃ ANTAGONIST

Prescriber Highlights

- Used in veterinary medicine primarily as an appetite stimulant & antiemetic in dogs & cats
- Can be used in conjunction with other antiemetics
- Primary side effect is sedation
- Use lowest effective dose to reduce sedative properties
- Do not exceed 30 mg per day when used for appetite stimulation

Monograph by Dinah Jordan, PharmD, DICVP

Uses/Indications

Currently, the only FDA approved indication for mirtazapine is depression in humans. Reported veterinary uses include treatment of chemotherapy-induced nausea and vomiting (CINV); anorexia associated with renal failure (azotemia), congestive heart failure, gastro-intestinal disorders, liver disease, or neoplasia. Other uses suggested include stress induced diseases; insomnia; post-pyometra symptoms; and post-operative inappetence. Studies have shown that mirtazapine also alleviated sleep apnea in rats and humans.

There are case reports published in human literature of mirtazapine use as treatment for non-mechanical vomiting after gastric bypass, CINV, obsessive-compulsive disorder, nociception and chronic pain, migraine headache prophylaxis, anti-psychotic induced akathisia, idiopathic nausea and vomiting, serotonin syndrome induced nausea, anorexia, irritable bowel syndrome, resistant hyperemesis gravidarum, and for the treatment of negative symptoms of schizophrenia. Studies in rats have also shown that mirtazapine significantly improves memory.

Pharmacology/Actions

The antidepressant activity of mirtazapine appears to be mediated by antagonism at central pre-synaptic α_2 -receptors, which normally act as a negative feedback mechanism that inhibits further norepinephrine (NE) release. By blocking these receptors, mirtazapine overcomes the negative feedback loop and results in a net increase in NE. This mechanism may also contribute to the appetite stimulating effects of the medication since NE acts at other α -receptors to increase appetite. Additionally, mirtazapine antagonizes several serotonin (5HT) receptor subtypes. The drug is a potent inhibitor of the 5HT₂ and 5HT₃ receptors and of histamine (H₁) receptors. Antagonism at the 5HT₃ receptors accounts for the anti-nausea and antiemetic effects of the drug, and its action at H₁-receptors produces prominent sedative effects. It is a moderate peripheral α_1 adrenergic antagonist, a property that may explain the occasional orthostatic hypotension associated with its use; it is a moderate antagonist of muscarinic receptors, which may explain the relatively low incidence of anticholinergic effects.

Pharmacokinetics

Complete pharmacokinetic information has not been published for dogs and cats to date. Following oral administration in humans, mirtazapine is rapidly and completely absorbed. Studies in rats showed a linear relationship between the effects of mirtazapine

ine and measured plasma and brain concentrations. Peak plasma concentrations are reached within about 2 hours after an oral dose in humans. Food has minimal effects on both the rate and extent of absorption and does not require adjustments in the dose. Oral bioavailability of mirtazapine is about 20% for rats and dogs, and about 50% for humans.

Mirtazapine is metabolized via multiple pathways and varies by species. In all species tested (humans and laboratory animals), the drug was metabolized via the following mechanisms: 8-hydroxylaton followed by conjugation, N-oxidation, and demethylation followed by conjugation. Humans and guinea pigs also produce metabolites via N-t-glucuronidation, whereas mice were the only species found to utilize demethylation followed by CO₂ addition and conjugation, and 13-hydroxylation followed by conjugation as methods of mirtazapine breakdown. These processes are conducted primarily by CYP2D6, CYP1A2, and CYP3A4, yet mirtazapine exerts minimal inhibition on any of these cytochromes. Several metabolic pathways of mirtazapine involve conjugation with glucuronide (glucuronidation). Since cats have a limited capacity for glucuronidation, mirtazapine is cleared less rapidly from the system and, therefore, an extended dosing interval is required.

It is estimated that the active metabolite of mirtazapine contributes only 3–6% of the total pharmacodynamic profile of the drug since it is approximately 10-fold less active than mirtazapine and affects the AUC minimally. Therefore, only the levels of the parent compound are considered clinically relevant.

The extent of binding of drugs to plasma proteins sometimes differs considerably among animal species. Plasma protein binding (PPB) for mirtazapine appears to be approximately 70–72% for mice, rats, and dogs, whereas for humans and rabbits it is approximately 85%. Despite the interspecies differences in PPB, no displacement interactions or dosage adjustments for mirtazapine are expected due to its large therapeutic window and nonspecific and relative low affinity for plasma proteins.

Human literature documents that elimination occurs via the urine (75%) and the feces (15%), renal impairment may reduce elimination by 30–50% compared to normal subjects, and hepatic impairment may reduce clearance by up to 30%. Human studies show the elimination half-life of mirtazapine to be long and range from 20–40 hours across age and gender subgroups, so dosage increases should take place no sooner than every 7–14 days. Females (both human and animal) of all ages exhibit significantly longer elimination half-lives than males (mean half-life of 37 hours for females vs. 26 hours for males in humans).

Contraindications/Precautions/Warnings

Mirtazapine is contraindicated in patients with hypersensitivity to mirtazapine or who have taken monoamine oxidase inhibitors (e.g., selegiline) in the past 14 days.

Mirtazapine has been associated with orthostatic hypotension in humans and should, therefore, be used with caution in patients with known cardiac disease or cerebrovascular disease that could be exacerbated by hypotension. Patients with renal impairment, renal failure, or hepatic disease should be monitored while on mirtazapine therapy.

Abrupt discontinuation of mirtazapine after long-term administration has resulted in withdrawal symptoms such as nausea, headache and malaise in humans. In general, antidepressants may affect blood glucose concentrations because of their indirect effects on the endocrine system; use with caution in patients with diabetes mellitus.

Mirtazapine exhibits very weak anticholinergic activity, consequently, vigilance should be used in patients who might be more susceptible to these effects, such as those with urinary retention,

prostatic hypertrophy, acute, untreated closed-angle glaucoma or increased intraocular pressure, or GI obstruction or ileus. Also, effects of mirtazapine may be additive to anticholinergic medications.

Extra care should be taken with active animals as mirtazapine may impair concentration and alertness. Although extremely rare, mirtazapine has been associated with blood dyscrasias in humans and should be used cautiously in patients with pre-existing hematological disease, especially leukopenia, neutropenia, or thrombocytopenia.

Adverse Effects

Mirtazapine appears to be well tolerated in both dogs and cats, but use has been limited and controlled trials are lacking. Besides the desirable side effect of appetite stimulation, other currently reported side effects in animals include drowsiness/sedation, vocalization, hypotension, tachycardia (all dose-dependent).

Reproductive/Nursing Safety

In humans, mirtazapine is FDA pregnancy category *C* (*animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans*). However, reproductive studies in rats, rabbits, and dogs have shown no evidence of teratogenicity. Additional studies in hamsters, rabbits, and rats showed no evidence of fetal genetic mutation or reduction in parental fertility, although there were increases in post-implantation losses and pup deaths, as well as decreased pup birth weight. No fetal harm was reported in any of several case reports of mirtazapine use during pregnancy nor in animal studies.

In animals, mirtazapine is excreted in very small amounts in milk, the implications of which are currently unknown; consequently, it may be prudent to use caution in nursing mothers. Mirtazapine is distributed into human breast milk and safe use in humans during nursing cannot be assured. In one case report mirtazapine concentrations were detected in breast milk, but the examining neuropsychiatrician detected no adverse effects (including weight gain or sedation) in the infant.

Overdosage/Acute Toxicity

Mirtazapine ingestion of upwards of 10-fold therapeutic dose in humans exhibits minimal toxicity requiring no acute intervention and only 6 hours of observation. Similar effects were seen in patients receiving up to 30 times the recommended dose. Despite these reports, the package insert for mirtazapine recommends that activated charcoal be administered in addition to other standard monitoring activities in an overdose situation.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mirtazapine and may be of significance in veterinary patients:

- **CLONIDINE:** Mirtazapine may cause increases in blood pressure
- **DIAZEPAM** (and other **benzodiazepines**): Minimal effects on mirtazapine blood levels, but may cause additive impairment of motor skills
- **FLUVOXAMINE:** May cause increased serum concentrations of mirtazapine
- **LINEZOLID:** Increased risk for serotonin syndrome
- **SELEGILINE, AMITRAZ:** Increased risk for serotonin syndrome; MAO inhibitors considered contraindicated with mirtazapine
- **TRAMADOL:** Increased risk for serotonin syndrome

In vitro studies identify mirtazapine as a substrate for several hepatic cytochrome CYP450 isoenzymes including 2D6, 1A2, and 3A4. Mirtazapine is not a potent inhibitor of any of these enzymes; clini-

cally significant pharmacokinetic interactions are not likely with drugs metabolized by CYP enzymes.

Laboratory Considerations

No specific concerns noted.

Doses

Since no safety or efficacy trials have been performed in animals to date, currently recommended doses are based on extrapolations from human medicine and clinical experience in veterinary practice. According to the product package insert and several anecdotal reports, no adjustment is needed in liver disease or kidney dysfunction, although starting at the lower end of the dosage range and titrating up if needed is recommended in such situations.

Note: At doses exceeding 30 mg per day, mirtazapine loses its appetite stimulating properties in humans. Since the ceiling dose for cats and dogs is not currently known, total daily doses ≤ 30 mg are recommended for appetite stimulation depending upon the weight of the pet.

■ DOGS:

As an appetite stimulant and/or antiemetic:

- a) 0.6 mg/kg PO q 24 h not to exceed 30 mg per day for appetite stimulation (Jordan 2007)
Dogs <20 lb. = 3.75 mg PO q24h;
21–50 lb. = 7.5 mg PO q 24h;
50–75 lb. = 15 mg PO q24h;
>75 lb. = 15 mg PO q12h or 30 mg PO q24h (once daily) (Jordan 2007)

■ CATS:

As an appetite stimulant and/or antiemetic:

- a) 3.75 mg PO q72h (every 3 days) (Jordan 2007)
- b) 3 mg per cat PO q72h (every 3 days) (Churchill 2006)
- c) 3–4 mg per cat PO q72h (every 3 days) (Scherk 2006)

Monitoring

- Clinical efficacy measured by the following parameters: increased appetite, decreased episodes of vomiting, and weight gain
- Adverse Effects

Client Information

- Give only the prescribed dose.
- Report excessive drowsiness or vocalization to your veterinarian.
- If your pet is receiving the orally disintegrating tablets, make sure hands are dry before handling the tablet. Place the tablet under the animal's tongue and hold mouth closed for several seconds to allow it to dissolve (should occur quickly). After the tablet has melted, offer the patient water.
- May be given without regard to food.

Chemistry/Synonyms

A member of the piperazino-azepine group of compounds, mirtazapine is classified as an atypical tetracyclic antidepressant and is not chemically related to other antidepressants. Mirtazapine, with a molecular weight of 265.36, occurs as a white to creamy white crystalline powder that is slightly soluble in water.

Mirtazapine may also be known as 6-azamianserin, Org-3770, mepirzapine and *Remeron*®; many trade names for international products are available.

Storage/Stability

The coated tablets and the orally disintegrating tablets should be stored at 25°C (77°F) with excursions permitted to 15–30°C (59–86°F). Protect from light and moisture. The stability of the orally disintegrating tablets once removed from the tablet blister is unknown and immediate use is recommended.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Mirtazapine Oral Tablets: 7.5 mg 15 mg, 30 mg, 45 mg; *Remeron*® (Organon), generic; (Rx)

Mirtazapine Orally Disintegrating Tablets: 15 mg, 30 mg, 45 mg; *Remeron SolTab*® (Organon), generic; (Rx)

MISOPROSTOL

(mye-soe-prost-ole) Cytotec®

PROSTAGLANDIN E₁ ANALOG

Prescriber Highlights

- Prostaglandin E₁ analog for treating or preventing gastric ulcers, especially associated with NSAIDs; may also be useful as an abortifacient, & to treat atopy or cyclosporine-induced nephrotoxicity
- Contraindications: Pregnancy, nursing mothers (diarrhea in the nursing offspring)
- Caution: Sensitivity to prostaglandins or prostaglandin analogs; patients with cerebral or coronary vascular disease
- Adverse Effects: GI distress (diarrhea, abdominal pain, vomiting, & flatulence); Potentially, uterine contractions & vaginal bleeding in female dogs
- Pregnant women should handle with caution

Uses/Indications

Misoprostol may be useful as primary or adjunctive therapy in treating or preventing gastric ulceration, especially when caused or aggravated by non-steroidal antiinflammatory drugs (NSAIDs). Misoprostol is most useful to prevent GI ulceration or GI adverse effects (anorexia, vomiting) associated with NSAID therapy. While it can be used for treating gastric ulcers, other drugs are probably just as effective and less expensive. It does not appear to be very effective in reducing gastric ulceration secondary to high dose corticosteroid therapy.

Misoprostol may be efficacious in reducing or reversing cyclosporine-induced nephrotoxicity. More data is needed to confirm this effect.

One study demonstrated that misoprostol can reduce the clinical signs associated with atopy somewhat in dogs.

Misoprostol's effects on uterine contractility and cervical softening/opening make it effective as an adjunctive treatment in pregnancy termination.

Pharmacology/Actions

Misoprostol has two main pharmacologic effects that make it a potentially useful agent. By a direct action on parietal cells, it inhibits basal and nocturnal gastric acid secretion as well as gastric acid

secretions that are stimulated by food, pentagastrin or histamine. Pepsin secretion is decreased under basal conditions, but not when stimulated by histamine.

Misoprostol also has a cytoprotective effect on gastric mucosa. Probably by increasing production of gastric mucosa and bicarbonate, increasing turnover and blood supply of gastric mucosal cells, misoprostol enhances mucosal defense mechanisms and healing in response to acid-related injuries.

Other pharmacologic effects of misoprostol include increased amplitude and frequency of uterine contractions, stimulating uterine bleeding, and causing total or partial expulsion of uterine contents in pregnant animals.

Pharmacokinetics

Approximately 88% of an oral dose of misoprostol is rapidly absorbed from the GI tract, but a significant amount is metabolized via the first-pass effect. The presence of food and antacids will delay the absorption of the drug. Misoprostol is rapidly de-esterified to misoprostol acid which is the primary active metabolite. Misoprostol and misoprostol acid are thought equal in their effects on gastric mucosa. Both misoprostol and the acid metabolite are fairly well bound to plasma proteins (approximately 90% bound). It is not believed that misoprostol enters maternal milk, but it is unknown whether the acid enters milk.

Misoprostol acid is further biotransformed via oxidative mechanisms to pharmacologically inactive metabolites. These metabolites, the free acid and small amounts of unchanged drug are principally excreted into the urine. In humans, the serum half-life of misoprostol is about 30 minutes and its duration of pharmacological effect is about 3–6 hours.

Contraindications/Precautions/Warnings

It should be used in patients with the following conditions only when its potential benefits outweigh the risks: Sensitivity to prostaglandins or prostaglandin analogs; patients with cerebral or coronary vascular disease (although not reported with misoprostol, some prostaglandins and prostaglandin analogs have precipitated seizures in epileptic human patients, and have caused hypotension which may adversely affect these patients).

Adverse Effects

The most prevalent adverse effect seen with misoprostol is GI distress, usually manifested by diarrhea, abdominal pain, vomiting, and flatulence. Adverse effects are often transient and resolve over several days or may be minimized by dosage adjustment or giving doses with food. Potentially, uterine contractions and vaginal bleeding could occur in female dogs.

Reproductive/Nursing Safety

Misoprostol is contraindicated during pregnancy due to its abortifacient activity. In humans, the FDA categorizes this drug as category **X** for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **D** (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

It is unlikely that misoprostol is excreted in milk because it is rapidly metabolized, however, it is not known if the active metabolite (misoprostol acid) is excreted in milk. Misoprostol is not recommended for nursing mothers as it potentially could cause significant diarrhea in the nursing offspring.

Overdosage/Acute Toxicity

There is limited information available. Overdoses in laboratory animals have produced diarrhea, GI lesions, emesis, tremors, focal cardiac, hepatic or renal tubular necrosis, seizures, and hypotension. Overdoses should be treated seriously and standard gut emptying techniques employed when applicable. Resultant toxicity should be treated symptomatically and supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving misoprostol and may be of significance in veterinary patients:

- **ANTACIDS, MAGNESIUM-CONTAINING:** Magnesium-containing antacids may aggravate misoprostol-induced diarrhea. If an antacid is required, an aluminum-only antacid may be a better choice. Antacids and food do reduce the rate of misoprostol absorption and may reduce the systemic availability, but probably do not affect therapeutic efficacy.

Doses

■ DOGS:

For the prevention and treatment of GI ulcers:

- a) 1–5 mcg/kg PO q8h (Haskins 2000)
- b) 3–4 mcg/kg PO q12h (Burrows 2004)
- c) 2–5 mcg/kg PO q8–12h (Dowling 2003a)

As an adjunctive therapy for the termination of mid-term pregnancy in the bitch:

- a) Pregnancy is confirmed with ultrasound and begun no sooner than 30 days after breeding. 1–3 mcg/kg misoprostol given intravaginally once daily concurrently with prostaglandin F2alpha (*Lutalyse*®) at 0.1 mg/kg SC three times daily for 3 days and then 0.2 mg/kg SC three times daily to effect. Monitor efficacy with ultrasound. (Cain 1999)

As an adjunctive therapy for atopic dermatitis:

- a) Target dosage of 5 mcg/kg PO three times daily. Modest improvement in clinical signs; relatively high cost. (Olivry, Dunston et al. 2003)
- b) 6 mcg/kg q8h PO for 30 days (Campbell 1999)

Monitoring

- Efficacy
- Adverse effects

Client Information

- Pregnant women should handle the drug with caution.
- If diarrhea or other GI adverse effects become severe or persist, reduce dose or give with food or aluminum antacids to alleviate. Severe diarrheas may require supportive therapy.

Chemistry/Synonyms

A synthetic prostaglandin E₁ analog, misoprostol occurs as a yellow, viscous liquid having a musty odor.

Misoprostol may also be known as: SC-29333, *Arthotec*®, *Arthrotec*®, *Artotec*®, *Artrenac Pro*®, *Artratec*®, *Condrotec*®, *Corrigast*®, *Cyprostol*®, *Cytotec*®, *Cytolog*®, *Diclotec*®, *Glefes*®, *Menpros*®, *Misodex*®, *Misofenac*®, *Naprateg*®, *Normulen*®, *Oxaprost*®, and *Symbol*®.

Storage/Stability/Compatibility

Misoprostol tablets should be stored in well-closed containers at room temperature. After manufacture, misoprostol has an expiration date of 18 months.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Misoprostol Tablets: 100 mcg & 200 mcg; *Cytotec*® (Pfizer); generic; (Rx)

MITOTANE

(mye-toe-tane) Lysodren®, o,p' – DDD

ADRENAL CYTOTOXIC; ANTINEOPLASTIC

Prescriber Highlights

- ▶ Adrenal cytotoxic agent used for medical treatment of pituitary-dependent hyperadrenocorticism
- ▶ Caution: Pregnancy, diabetes, & preexisting renal or hepatic disease
- ▶ Adverse Effects: Lethargy, ataxia, weakness, anorexia, vomiting, &/or diarrhea; liver changes possible
- ▶ Relapses are not uncommon
- ▶ All dogs receiving mitotane therapy should receive additional glucocorticoid supplementation if undergoing a stress (e.g., surgery, trauma, acute illness)
- ▶ Monitoring is mandatory
- ▶ Avoid human exposure

Uses/Indications

In veterinary medicine, mitotane is used primarily for the medical treatment of pituitary-dependent hyperadrenocorticism (PDH), principally in the dog. It has also been used for the palliative treatment of adrenal carcinoma in humans and dogs.

Pharmacology/Actions

While mitotane is considered an adrenal cytotoxic agent, it apparently can also inhibit adrenocortical function without causing cell destruction. The exact mechanisms of action for these effects are not clearly understood.

In dogs with pituitary-dependent hyperadrenocorticism (PDH), mitotane has been demonstrated to cause severe, progressive necrosis of the zona fasciculata and zona reticularis. These effects occur quite rapidly (usually within 5–10 days of starting therapy). It has been stated that mitotane spares the zona glomerulosa and therefore aldosterone synthesis is unaffected. This is only partially true, as the zona glomerulosa may also be affected by mitotane therapy, but it is uncommon for clinically significant effects on aldosterone production to be noted with therapy.

Pharmacokinetics

In dogs, the systemic bioavailability of mitotane is poor. Oral absorption can be enhanced by giving the drug with food (especially food high in oil/fat content). In humans, approximately 40% of an oral dose of mitotane is absorbed after dosing, with peak serum levels occurring about 3–5 hours after a single dose. Distribution of the drug occurs to virtually all tissues in the body. The drug is stored in the fat and does not accumulate in the adrenal glands. A small amount may enter the CSF. It is unknown if the drug crosses the placenta or is distributed into milk.

Mitotane has a very long plasma half-life in humans, with values ranging from 18–159 days being reported. Serum half-lives may increase in a given patient with continued dosing, perhaps due to a depot effect from adipose tissue releasing the drug. The drug is metabolized in the liver and is excreted as metabolites in the urine and bile. Approximately 15% of an oral dose is excreted in the bile, and 10% in the urine within 24 hours of dosing.

Contraindications/Precautions/Warnings

Mitotane is contraindicated in patients known to be hypersensitive to it. Patients with concurrent diabetes mellitus may have rapidly changing insulin requirements during the initial treatment period. These animals should be closely monitored until they are clinically stable.

Dogs with preexisting renal or hepatic disease should receive the drug with caution and with more intense monitoring.

It has been stated that “. . . hyperadrenocorticism is a clinical condition. No dog should be treated for this condition unless there are obvious clinical signs, consistent with the diagnosis, that are worrisome to the owner.” (Feldman 2007)

Some clinicians recommend giving prednisolone at 0.2 mg/kg/day during the initial treatment period (0.4 mg/kg/day to diabetic dogs) to reduce the potential for side effects from acute endogenous steroid withdrawal. Other clinicians have argued that routinely administering steroids masks the clinical markers that signify when the endpoint of therapy has been reached and must be withdrawn 2–3 days before ACTH stimulation tests can be done. Since in adequately observed patients adverse effects requiring glucocorticoid therapy may only be necessary in 5% of patients, the benefits of routine glucocorticoid administration may not be warranted.

Adverse Effects

Most common adverse effects seen with initial therapy in dogs include lethargy, ataxia, weakness, anorexia, vomiting, and/or diarrhea. Adverse effects are commonly associated with plasma cortisol levels of less than 1 micrograms/dl or a too rapid decrease of plasma cortisol levels into the normal range. Adverse effects may also be more commonly seen in dogs weighing less than 5 kg, which may be due to the inability to accurately dose. The incidence of one or more of these effects is approximately 25% and they are usually mild. If adverse effects are noted, it is recommended to temporarily halt mitotane therapy and supplement with glucocorticoids. Owners should be provided with a small supply of prednisolone tablets to initiate treatment. Should the clinical signs persist 3 hours after steroids are supplemented, consider other medical problems. Liver changes (congestion, centrilobular atrophy, and moderate to severe fatty degeneration) have been noted in dogs given mitotane. Although not commonly associated with clinical symptomatology, these effects may be more pronounced with long-term therapy or in dogs with preexisting liver disease.

In perhaps 5% of dogs treated, long-term glucocorticoid and sometimes mineralocorticoid replacement therapy may be required. All dogs receiving mitotane therapy should receive additional glucocorticoid supplementation if undergoing a stress (e.g., surgery, trauma, acute illness).

Relapses are not uncommon in canine patients treated for Cushing's with mitotane.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **D**

(Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.)

It is not known whether this drug is excreted in maternal milk. Because of the potential for adverse reactions in nursing offspring, decide whether to discontinue nursing or discontinue the drug.

Overdosage/Acute Toxicity

No specific recommendations were located regarding overdoses of this medication. Because of the drug's toxicity and long half-life, emptying the stomach and administering charcoal and a cathartic should be considered after a recent ingestion. It is recommended that the patient be closely monitored and given glucocorticoids if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mitotane and may be of significance in veterinary patients:

- **CNS DEPRESSANT DRUGS:** If mitotane is used concomitantly with drugs that cause CNS depression, additive depressant effects may be seen
- **INSULIN:** Diabetic dogs receiving insulin may have their insulin requirements decreased when mitotane therapy is instituted
- **PHENOBARBITAL:** Can induce enzymes and reduce the efficacy of mitotane, conversely mitotane can induce hepatic microsomal enzymes and increase the metabolism of phenobarbital
- **SPIRONOLACTONE:** In dogs, spironolactone has been demonstrated to block the action of mitotane; it is recommended to use an alternate diuretic if possible

Laboratory Considerations

- Mitotane will bind competitively to thyroxine-binding globulin and decreases the amount of serum protein-bound iodine. Serum **thyroxine** concentrations may be unchanged or slightly decreased, but free thyroxine values remain in the normal range. Mitotane does not affect the results of the resin triiodothyronine uptake test.
- Mitotane can reduce the amounts measurable **17-OHCS** in the urine, which may or may not reflect a decrease in serum cortisol levels or adrenal secretion.

Doses

■ DOGS:

For medical treatment of pituitary-dependent hyperadrenocorticism (bilateral adrenal hyperplasia): **Note:** The information provided below (in "a and b") is a synopsis of the referenced authors' treatment protocols. It is strongly recommended to refer to the original references or other detailed discussions on the treatment of hyperadrenocorticism before instituting therapy for the first time.

- a) Beginning by reducing dog's food allotment by one-third the day before (Saturday) therapy. Owners should give 1/3 the daily allotment that morning and 1/3 the daily allotment that evening. This should make the dog quite hungry. No dog with a poor appetite should ever be treated medically for pituitary-dependent hyperadrenocorticism (PDH). Initiate therapy at home (on Sunday): 25 mg/kg twice a day, PO with food. Glucocorticoids are not routinely administered nor dispensed. Give until one of the following occurs: Polydipsic dogs' water consumption approaches 60 mL/kg/day of water, dog takes longer to consume a meal or it develops partial or complete anorexia, dog vomits, is unusually listless, or has diarrhea. Any of these observations demand the owner stop therapy and have the dog examined by a veterinarian. Any

reduction in appetite indicates that the induction phase of therapy is completed. Water intake is a less-consistent parameter in determining therapeutic end-point. Beginning on 2nd day of therapy, contact owner daily during the induction phase to monitor the situation and encourage.

When dog's appetite is reduced or 8 days of induction therapy have occurred (whichever comes first), history and physical repeated, ACTH response test, BUN, serum sodium, and potassium redone. If the dog has responded clinically, stop mitotane until ACTH response test can be evaluated. Successful therapy is indicated by pre- and post-ACTH serum cortisol concentrations >1.5 mcg/dl and <5 mcg/dl. Goals of therapy are to achieve resolution of clinical signs. Most dogs respond between 4 and 9 days of therapy.

Maintenance therapy: Is begun once dog seems much improved or normal to owner or if post-ACTH serum cortisol is <5 mcg/dL (**Note:** reference states 54g/dL, but this is an obvious "typo"). Each dog must be treated individually. Dogs generally receive 25–50 mg/kg per week. If <1 mcg/dl, withhold medication for 2 weeks and restart at 25 mcg/kg/week. Whenever possible, the weekly dose of medication should be divided in as many doses as possible (e.g., if dog receiving 500 mg/week; divide tablet into quarters and give 4 times a week). Four weeks after therapy started, ACTH stimulation test rechecked. If post-ACTH results are 1–3.5 mcg/dl, dog receives 25 mg/kg/week and recheck in 4 weeks. If 3.5–7.5 mcg/dl, dog receives 50 mg/kg/week and recheck in 4 weeks. If >7.5 mcg/dl be sure the drug is being administered properly. If given properly, may mix with corn oil and mixed with food. These animals should also be evaluated for other conditions (e.g., renal disease, diabetes mellitus). ACTH stimulation results should be used as a guide for dosage adjustment, but owner opinion is the most important factor. (Feldman 1989), (Feldman 2000), (Feldman 2007)

- b) Induction phase 30–50 mg/kg/day PO with a meal once daily or divided q12h for 7–10 days. If adverse effects (lethargy, vomiting, weakness, diarrhea) occur, discontinue mitotane and give glucocorticoids (prednis(ol)one at 0.15–0.25 mg/kg/day) until dog can be evaluated. If decreased appetite occurs discontinue mitotane and evaluate with an ACTH stimulation test. Perform ACTH stimulation test at end of 10 day period or sooner if adverse effects occur. Goal is to have basal and post-ACTH cortisol between 1–5 mcg/dl (normal for most labs). If basal and post ACTH cortisol falls below 1 mcg/dl, temporarily suspend mitotane and supplement with glucocorticoids until circulating cortisol normalizes (usually 2–4 weeks, but may take several weeks to months). If basal or post ACTH cortisol is above normal, continue daily mitotane and recheck ACTH stimulation tests at 5–10 day intervals until serum cortisol falls within normal resting range.

Begin maintenance when desired cortisol concentrations are documented by ACTH stimulation testing. Mitotane given initially at 35–50 mg/kg per week in 2–3 divided doses. Should adverse effects, discontinue mitotane and supplement with glucocorticoids until dog can be evaluated by serum electrolytes and ACTH stimulation test. (Kintzer 2007)

- c) Intentionally causing complete destruction of the adrenal cortex as an alternative to the traditional mitotane treatment: Mitotane at 75–100 mg/kg per day for 25 consecutive days, given in 3–4 doses per day with food. Lifelong prednisone at 0.1–0.5 mg/kg PO twice daily initially and mineralocorticoid therapy is begun at the start of mitotane therapy. Prednisone dose is tapered after completion of the 25-day protocol. Re-

lapse is common and periodic ACTH stimulation testing is necessary. May be considerably more expensive than traditional therapy because of the expense associated with treating Addisonian dogs. (Nelson 2003c)

- d) For total adrenal ablation for management of Cushing's: Mitotane 100 mg/kg/day divided twice daily for 30 days. Supplemental cortisone acetate 2 mg/kg/day divided twice daily and fludrocortisone acetate 0.1 mg/ 10 lb of body weight PO once daily are begun on day 1 of mitotane therapy. Diet is supplemented with 1–5 grams of sodium chloride per day. One week after induction phase with mitotane, cortisone acetate is reduced to 1 mg/kg/day. Electrolytes and ACTH stimulation test are performed at end of induction, every 6 months, and at any time animal demonstrates signs compatible with either hypo- or hyperadrenocorticism. This form of management requires close patient monitoring and life-long daily therapy. Close attention during stress and non-adrenal illnesses required. (Bruyette 2002a)

For palliative medical treatment of adrenal carcinomas or medical treatment of adrenal adenomas:

Initially, 50–75 mg/kg PO in daily divided doses for 10–14 days. May supplement with predniso(lo)ne at 0.2 mg/kg/day. Stop therapy and evaluate dog if adverse effects occur. After initial therapy run ACTH-stimulation test (do not give predniso(lo)ne the morning of the test). If basal or post-ACTH serum cortisol values are decreased, but still above the therapeutic end-point (<1 micrograms/dl), repeat therapy for an additional 7–14 days and repeat testing. If post-ACTH serum cortisol values remain greatly elevated or unchanged, increase mitotane to 100 mg/kg/day and repeat ACTH-stimulation test at 7–14 day intervals. If ACTH continues to remain greatly elevated, increase dosage by 50 mg/kg/day every 7–14 days until response occurs or drug intolerance ensues. Adjust dosage as necessary as patient tolerates or ACTH-responsive dictates. Once undetectable or low-normal post-ACTH cortisol levels are attained, continue mitotane at 100–200 mg/kg/week in divided doses with glucocorticoid supplementation (predniso(lo)ne 0.2 mg/kg/day). Repeat ACTH-stimulation test in 1–2 months. Continue at present dose if cortisol remains below 1 micrograms/dl. Should cortisol increase to 1–4 micrograms/dl, increase maintenance dose by 50%. If basal or post-ACTH cortisol goes above 4 micrograms/dl, restart daily treatment (50–100 mg/kg/day) as outlined above. Once patient is stabilized, repeat ACTH-stimulation tests at 3–6 month intervals. (Kintzer and Peterson 1989)

■ FERRETS:

For medical treatment of hyperadrenocorticism where surgery has not been performed or tumor has not been fully resected:

- a) 50 mg per ferret PO once daily for one week, then 50 mg PO 2–3 times per week. Have a compounding pharmacy make 50 mg capsules. Capsules can be easily administered if coated with a substance such as *Nutrical*. (Rosenthal and Peterson 2000)

Monitoring

Initially and as needed (see doses above):

- Physical exam and history (including water and food consumption, weight)
- BUN, CBC, Liver enzymes, Blood glucose, ACTH response test, serum electrolytes (Na⁺/K⁺)

Client Information

- Clients must be clearly instructed in the adverse effects of the drug and the clinical signs of acute hypoadrenocorticism
- This medication is best administered immediately after a meal
- Because of the potential severe toxicity associated with this agent, clients should be instructed to wear gloves or wash their hands after administering and to keep the tablets out of reach of children or pets.

Chemistry/Synonyms

Mitotane, also commonly known in veterinary medicine as o,p'-DDD, is structurally related to the infamous insecticide, chlorophenothane (DDT). It occurs as a white, crystalline powder with a slightly aromatic odor. It is practically insoluble in water and soluble in alcohol.

Mitotane may also be known as: CB-313, o,p'DDD, NSC-38721, WR-13045, and *Lisodren*®.

Storage/Stability

Mitotane tablets should be stored at room temperature (15–30°C), in tight, light resistant containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Mitotane Tablets (scored): 500 mg; *Lysodren*® (Bristol-Myers Squibb Oncology); (Rx)

MITOXANTRONE HCL

(mye-toe-zan-trone) Novantrone®

ANTINEOPLASTIC

Prescriber Highlights

- ▶ Antineoplastic that may be useful for a variety of neoplastic diseases
- ▶ Contraindications (relative): Myelosuppression, concurrent infection, impaired cardiac function; those who have received prior cytotoxic drug or radiation exposure
- ▶ Caution: Sensitivity to drug, hyperuricemia or hyperuricuria, impaired hepatic function
- ▶ Adverse Effects: Dose-dependent GI distress, bone marrow depression, lethargy, & seizures (cats)
- ▶ Relatively expensive
- ▶ Renal clearance of drug is minimal

Uses/Indications

Mitoxantrone may be useful in the treatment of several neoplastic diseases in dogs and cats, including lymphosarcoma mammary adenocarcinoma, squamous cell carcinoma, renal adenocarcinoma, fibroid sarcoma, thyroid or transitional cell carcinomas, and hemangioepithelioma.

Because renal clearance of the drug is minimal (10%), it may be administered to cats with renal insufficiency much more safely than doxorubicin.

Pharmacology/Actions

By intercalation between base pairs and a nonintercalative electrostatic interaction, mitoxantrone binds to DNA and inhibits both DNA and RNA synthesis. Mitoxantrone is not cell-cycle phase specific, but appears to be most active during the S phase.

Pharmacokinetics

Mitoxantrone is rapidly and extensively distributed after intravenous infusion. Highest concentrations of the drug are found in the liver, heart, thyroid, and red blood cells. In humans, it is approximately 78% bound to plasma proteins. Mitoxantrone is metabolized in the liver, but the majority of the drug is excreted unchanged in the urine. Half-life of the drug in humans averages about 5 days as a result of the drug being taken up, bound by, and then slowly released by tissues.

Contraindications/Precautions/Warnings

Mitoxantrone is relatively contraindicated (weigh risk vs. benefit) in patients with myelosuppression, concurrent infection, impaired cardiac function, or those who have received prior cytotoxic drug or radiation exposure. It should be used with caution in patients with sensitivity to mitoxantrone, hyperuricemia or hyperuricuria, or impaired hepatic function.

Adverse Effects

In dogs and cats, effects include dose-dependent GI distress (vomiting, anorexia, diarrhea) and bone marrow depression (sepsis). White cell nadirs generally occur on day 10. Some evidence exists that by giving recombinant granulocyte-colony stimulating factor bone marrow depression severity and duration may be reduced. Lethargy may also be noticed. Some cats receiving this drug have also developed seizures.

Unlike doxorubicin, cardiotoxicity has not yet been reported in dogs and only rarely occurs in humans. Other adverse effects less frequently or rarely noted in humans and, potentially possible in dogs, include conjunctivitis, jaundice, renal failure, seizures, allergic reactions, thrombocytopenia, irritation or phlebitis at injection site. Tissue necrosis associated with extravasation has only been reported in a few human cases.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Mitoxantrone is excreted in maternal milk and significant concentrations (18 ng/mL) have been reported for 28 days after the last administration to humans. Because of the potential for serious adverse reactions in offspring, it is recommended to use milk replacer if mitoxantrone is administered.

Overdosage/Acute Toxicity

Because of the potential serious toxicity associated with this agent, dosage determinations must be made carefully.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mitoxantrone and may be of significance in veterinary patients:

■ **DOXORUBICIN, DAUNORUBICIN, or RADIATION THERAPY:** Cardiotoxicity risks may be enhanced in patients that have previously received doxorubicin, daunorubicin, or radiation therapy to the mediastinum

■ **IMMUNOSUPPRESSANT DRUGS** (e.g., azathioprine, cyclophosphamide, corticosteroids): Use with other immunosuppressant drugs may increase the risk of infection

■ **MYELOSUPPRESSIVE DRUGS** (e.g., chloramphenicol, flucytosine, amphotericin B, or colchicine): Use extreme caution when used concurrently with other drugs that are also myelosuppressive, including many of the other antineoplastics and other bone marrow depressant drugs; bone marrow depression may be additive

■ **VACCINES, LIVE:** Live virus vaccines should be used with caution, if at all, during therapy

Laboratory Considerations

■ Mitoxantrone may raise serum **uric acid** levels. Drugs such as allopurinol may be required to control hyperuricemia.

■ **Liver function tests** may become abnormal, indicating hepatotoxicity.

■ Mitoxantrone may discolor **urine** a green-blue.

Doses

For more information on using mitoxantrone as part of chemotherapy protocols, refer to the protocols found in the appendix or other dosages/protocols found in numerous references, including: *Withrow and MacEwen's Small Animal Clinical Oncology, 4th Ed.* (Withrow and Vail 2007); *Canine and Feline Geriatric Oncology* (Villalobos 2007); *Small Animal Internal Medicine, 3rd Edition* (Nelson and Couto 2003); *Textbook of Veterinary Internal Medicine: Diseases of the Dog and Cat 6th Edition* (Ettinger and Feldman 2005); and *The 5-Minute Veterinary Consult Canine & Feline, 3rd Ed.* (Tilley and Smith 2004).

■ DOGS:

As an alternative agent for the treatment of a variety of neoplastic diseases (see Indications above):

- For transitional cell carcinoma: 5 mg/m² IV every 21 days with piroxicam (0.3 mg/kg PO once daily). (Chun 2007a)
- For lymphoma, squamous cell carcinoma, transitional cell carcinoma, mammary gland tumors, etc.: Effective dose is 6 mg/m² IV every 2–3 weeks (Ogilvie 2003a)
- As a single rescue agent for lymphoma: 5.5–6 mg/m² IV every 3 weeks (Meleo 2003)
- As a rescue agent for canine lymphoma: 6 mg/m² IV every 2–3 weeks. Check CBC on day 7 after treatment and the protocol can be repeated on day 14 or 21 if the dog attains complete or partial response. Combining with DTIC (dacarbazine) may improve the response rate for dogs with refractory lymphoma, but there are no available studies. (Rassnick 2006)
- For lymphoproliferative disorders: 5–6 mg/m² every 3 weeks (Gilson and Page 1994)
- For transitional cell carcinoma after laser ablation of the primary tumor: Mitoxantrone at 5 mg/m² IV every 3 weeks for 4 treatments. Piroxicam was given at a dosage of 0.3 mg/kg PO once daily for the remaining life of the dog. (Upton, Tanger et al. 2006)

■ CATS:

- For soft-tissue sarcomas: 6–6.5 mg/m² IV given every 3–4 weeks for 4–6 treatments. (Keller and Helfand 1994)
- Effective dose: 6.5 mg/m² IV every 2–3 weeks (Ogilvie 2003a)
- As a single rescue agent for lymphoma: 6–6.5 mg/m² IV every 3 weeks (Meleo 2003)

Monitoring

- CBC with differential and platelets (see Adverse Effects section)
- Efficacy
- Chest radiographs, ECG or other cardiac function tests if cardiac symptomatology present
- Liver function tests if jaundice or other clinical signs of hepatotoxicity present
- Serum uric acid levels for susceptible patients

Client Information

- Clients should understand the potential costs and toxicities associated with therapy
- A blue-green color to urine or a bluish color to sclera may be noted but is of no concern
- Have clients report any clinical signs associated with toxicity immediately to veterinarian

Chemistry/Synonyms

Mitoxantrone HCl is a synthetic anthracenedione antineoplastic. It occurs as a dark-blue powder and is sparingly soluble in water, practically insoluble in acetone, acetonitrile, and chloroform, and slightly soluble in methyl alcohol.

Mitoxantrone may also be known as: L-232315, DHAD, dihydroxyanthracenedione dihydrochloride, mitoxantroni hydrochloridum, NSC-301739, *Formyxan*®, *Genefadrone*®, *Micraleve*®, *Misostol*®, *Mitoxal*®, *Mitoxgen*®, *Mitroxone*®, *Neotalem*®, *Novantron*®, *Novantrone*®, *Oncotron*®, *Onkotrone*®, or *Pralifan*®.

Storage/Stability/Compatibility

Mitoxantrone HCl should be stored at room temperature. While the manufacturer recommends not to freeze, one study (Mauldin 2002) demonstrated that the drug maintained its cytotoxic effects when frozen and thawed at various intervals over a 12 month period. Do not mix or use the same IV line with heparin infusions (precipitate may form). At present, it is not recommended to mix with other IV drugs.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Mitoxantrone HCl for Injection: 2 mg (mitoxantrone free base)/mL, preservative free in 10 mL, 12.5 mL, and 15 mL multi-dose vials; *Novantrone*® (Serono); (Rx)

MORANTEL TARTRATE

(mor-an-tel) Rumatel®

ANTIPARASITIC AGENT

Prescriber Highlights

- ▶ Infrequently used anthelmintic for ruminants
- ▶ Contraindications: None
- ▶ Adverse Effects: Large safety margin; clinical signs of OD include increased respiratory rates, profuse sweating, ataxia or other cholinergic effects

Uses/Indications

Morantel is labeled for the removal of the following parasites in cattle: Mature forms of: *Haemonchus* spp., *Ostertagia* spp., *Trichostrongylus* spp., *Nematodirus* spp., *Cooperia* spp. and *Oesophagostomum radiatum*. It is also used in other ruminant species.

Pharmacology/Actions

Like pyrantel, morantel acts as a depolarizing neuromuscular blocking agent in susceptible parasites, thereby paralyzing the organism. The drug possesses nicotine-like properties and acts similarly to acetylcholine. Morantel also inhibits fumarate reductase in *Haemonchus* spp.

Morantel is slower than pyrantel in its onset of action, but is approximately 100 times as potent.

Pharmacokinetics

After oral administration, morantel is absorbed rapidly from the upper abomasum and small intestine. Peak levels occur about 4–6 hours after dosing. The drug is promptly metabolized in the liver. Within 96 hours of administration, 17% of the drug is excreted in the urine with the remainder in the feces.

Contraindications/Precautions/Warnings

There are no absolute contraindications to using this drug.

Adverse Effects

At recommended doses, adverse effects are not commonly seen. For more information, see Overdosage section below.

Reproductive/Nursing Safety

Morantel is considered generally safe to use during pregnancy.

Overdosage/Acute Toxicity

Morantel tartrate has a large safety margin. In cattle, dosages of up to 200 mg/kg (20 times recommended dose) resulted in no toxic reactions. The LD₅₀ in mice is 5 g/kg. Clinical signs of toxicity that might possibly be seen include increased respiratory rates, profuse sweating (in species with sweat glands), ataxia or other cholinergic effects.

Chronic toxicity studies have been conducted in cattle and sheep. Doses of 4 times recommended were given to sheep with no detectable deleterious effects. Cattle receiving 2.5 times recommended dose for 2 weeks showed no toxic signs.

Drug Interactions

- **BENTONITE:** Do not add to feeds containing bentonite.
- **LEVAMISOLE, PYRANTEL:** Because of similar mechanisms of action (and toxicity), morantel is not recommended for use concurrently with pyrantel or levamisole.
- **ORGANOPHOSPHATES, DIETHYLCARBAMAZINE:** Observation for adverse effects should be intensified if used concomitantly with an organophosphate or diethylcarbamazine.
- **PIPERAZINE:** Has antagonistic mechanism of action; do not use with morantel.

Doses

■ CATTLE:

For susceptible parasites:

- 9.68 mg/kg PO (Paul 1986)
- Feed at the rate of 0.44 g of morantel tartrate per 100 lbs of body weight. 10 lbs of premix per ton of food per 100 lbs of body weight. (Label Directions; *Rumatel*®—Philbro)
- 8.8 mg/kg PO (Roberson 1988b)

■ SHEEP & GOATS:

For susceptible parasites:

- Goats: As a single therapeutic treatment at 0.44 grams morantel tartrate per 100 lb. body weight. Fresh water should be available at all times. Conditions of constant worm exposure may require retreatment in 2–4 weeks. (Label directions; *Goat Care-2X*®—Durvet)
- Sheep: 10 mg/kg PO (Roberson 1988b)
- Goats: 10 mg/kg PO (de la Concha 2002)

Chemistry/Synonyms

A tetrahydropyrimidine anthelmintic, morantel tartrate occurs as a practically odorless, off-white to pale yellow, crystalline solid that is soluble in water. It has a melting range of 167–171°C. The tartrate salt is equivalent to 59.5% of base activity.

Morantel tartrate may also be known as: CP-12009-18, moranteli hydrogenotartras, or UK-2964-18, *Goat Care-2X*® and *Rumatel*®.

Storage/Stability

Morantel tartrate products should be stored at room temperature (15–30°C, 59–86°F) and protected from light unless otherwise instructed by the manufacturer.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Morantel Tartrate Medicated Pellets: 0.194% (880 mg/lb) in 3 lb (treats 12–50 lb goats) and 10 lb. (treats 40–50 lb. goats). *Goat Care-2X*® (Durvet); (OTC); No withdrawal time noted on label. Do not mix in feeds containing bentonite.

Morantel Tartrate Medicated Premix: 88 g morantel tartrate per lb. in 25 lb bags: *Rumatel*® Medicated Premix-88 (Philbro); (OTC). Approved for use in beef or dairy cattle. Milk withdrawal (at labeled doses) = none; Slaughter withdrawal (at labeled doses) = 14 days

HUMAN-LABELED PRODUCTS: None

Uses/Indications

Morphine is used for the treatment of acute pain in dogs, cats, horses, swine, sheep, and goats. It may be used as a preanesthetic agent in dogs and swine. Additionally, it has been used as an antitussive, antidiarrheal, and as adjunctive therapy for some cardiac abnormalities (see doses) in dogs.

Pharmacology/Actions

The morphine-like agonists (morphine, meperidine, oxymorphone) have primary activity at the *mu* receptors, with some activity possible at the delta receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include: CNS: euphoria, sedation, and confusion. *Cardiovascular*: bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. *Urinary*: Increased bladder sphincter tone can induce urinary retention.

Morphine's CNS effects are irregular and are species specific. Cats, horses, sheep, goats, cattle, and swine may exhibit stimulatory effects after morphine injection, while dogs, humans, and other primates exhibit CNS depression. Both dogs and cats are sensitive to the emetic effects of morphine, but significantly higher doses are required in cats before vomiting occurs. This effect is a result of a direct stimulation of the chemoreceptor trigger zone (CTZ). Other species (horses, ruminants, and swine) do not respond to the emetic effects of morphine. Like meperidine, morphine can affect the release of histamine from mast cells.

Morphine is an effective centrally acting antitussive in dogs. Following morphine administration, hypothermia may be seen in dogs and rabbits, while hyperthermia may be seen in cattle, goats, horses, and cats. Morphine can cause miosis (pinpoint pupils) in humans, rabbits, and dogs.

While morphine is considered a respiratory depressant, respirations are stimulated initially in dogs. Panting may ensue which may be a result of increased body temperature. Often however, body temperature may be reduced due to a resetting of the "body's thermostat." As CNS depression increases and the hyperthermia resolves, respirations can become depressed. Morphine at moderate to high doses can also cause bronchoconstriction in dogs.

The cardiovascular effects of morphine in dogs are in direct contrast to its effects on humans. In dogs, morphine causes coronary vasoconstriction with resultant increase in coronary vascular resistance, and a transient decrease in arterial pressure. Both bradycardias and tachycardias have been reported in dogs. While morphine has been used for years as a sedative/analgesic in the treatment of myocardial infarction and congestive heart failure in people, its effects on dogs make it a less than optimal choice in canine patients with clinical signs of cardiopulmonary failure. However, its use has been recommended by several clinicians in the initial treatment for cardiogenic edema.

The effects of morphine on the gastrointestinal (GI) tract consist primarily of a decrease in motility and secretions. The dog, however, will immediately defecate following an injection of morphine, then exhibit the signs of decreased intestinal motility and, ultimately, constipation can result. Both biliary and gastric secretions are reduced following administration of morphine, but gastric secretion of HCl will later be compensated by increased (above normal) acid secretion.

Initially, morphine can induce micturition, but with higher doses (>2.4 mg/kg IV) urine secretion can be substantially reduced by an increase in anti-diuretic hormone (ADH) release. Morphine

MORPHINE SULFATE

(*mor-feen*)

OPIATE AGONIST

Prescriber Highlights

- ▶ Classic opiate analgesic
- ▶ Contraindications: Hypersensitivity to morphine, diarrhea caused by a toxic ingestion
- ▶ Extreme Caution: Respiratory disease or from acute respiratory dysfunction
- ▶ Caution: Hypothyroidism, severe renal insufficiency (acute uremia), adrenocortical insufficiency, geriatric or severely debilitated patients, head injuries or increased intracranial pressure, & acute abdominal conditions (e.g., colic)
- ▶ Adverse Effects: Histamine release, respiratory depression, bronchoconstriction, CNS depression, physical dependence (chronic use), hyperthermia (cattle, goats, horses & cats), hypothermia (dogs, rabbits); GI Gastrointestinal effects may include: (nausea, vomiting, & decreased intestinal peristalsis), defecation (dogs)
- ▶ C-II controlled substance

may cause bladder hypertonia which can lead to increased difficulty in urination.

Pharmacokinetics

Morphine is absorbed when given by IV, IM, SC, and rectal routes. Although absorbed when given orally, bioavailability is reduced, probably because of a high first-pass effect. Morphine concentrates in the kidney, liver, and lungs; lower levels are found in the CNS. Although at lower levels than in the parenchymatous tissues, the majority of free morphine is found in skeletal muscle. Morphine crosses the placenta and narcotized newborns can result if mothers are given the drug before giving birth. These effects can be rapidly reversed with naloxone. Small amounts of morphine will also be distributed into the milk of nursing mothers.

The major route of elimination of morphine is by metabolism in the liver, primarily by glucuronidation. Because cats are deficient in this metabolic pathway, half-lives in cats are probably prolonged. The glucuronidated metabolite is excreted by the kidney.

After IV administration in dogs, morphine has a volume of distribution of about 7.5 L/kg and a clearance of approximately 83 mL/min/kg. Its elimination half-life is slightly longer than 1 hour. The oral bioavailability of the extended release tablets is widely variable and this dosage form of the drug is erratically absorbed in dogs.

In horses, the serum half-life of morphine has been reported to be 88 minutes after a dose of 0.1 mg/kg IV. At this dose the drug was detectable in the serum for 48 hours and in the urine for up to 6 days. The half-life in cats has been reported to be approximately 3 hours.

Contraindications/Precautions/Warnings

All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), and in geriatric or severely debilitated patients. Morphine is contraindicated in cases where the patient is hypersensitive to narcotic analgesics, receiving monamine oxidase inhibitors (MAOIs), or with diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract.

Morphine should be used with extreme caution in patients with head injuries, increased intracranial pressure, and acute abdominal conditions (e.g., colic) as it may obscure the diagnosis or clinical course of these conditions. Morphine may also increase intracranial pressure secondary to cerebral vasodilatation as a result of increased $p_a\text{CO}_2$ stemming from respiratory depression. It should be used with extreme caution in patients suffering from respiratory disease or from acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation).

Because of its effects on vasopressin (ADH), morphine must be used cautiously in patients suffering from acute uremia. Urine flow has been reported to decrease by as much as 90% in dogs given large doses of morphine.

Neonatal, debilitated, or geriatric patients may be more susceptible to the effects of morphine and may require lower dosages. Patients with severe hepatic disease may have prolonged duration of action of the drug.

Opiate analgesics are contraindicated in patients who have been stung by the scorpion species *Centruroides sculpturatus* Ewing and *C. gertschi* Stahnke as they can potentiate these venoms.

Adverse Effects

At usual doses, the primary concern is the effect the opioids have on respiratory function. Decreased tidal volume, depressed cough reflex, and the drying of respiratory secretions may all have a detrimental effect on a susceptible patient. Bronchoconstriction (secondary to histamine release?) following IV doses has been noted in dogs.

Gastrointestinal effects may include: nausea, vomiting, and decreased intestinal peristalsis. Dogs will usually defecate after an initial dose of morphine. Horses exhibiting signs of mild colic may have their clinical signs masked by the administration of narcotic analgesics.

The CNS effects of morphine are dose and species specific. Animals that are stimulated by morphine may elicit changes in behavior, appear restless and, at very high doses, have convulsions. The CNS depressant effects seen in dogs may encumber the abilities of working animals.

Body temperature changes may be seen. Cattle, goats, horses, and cats may exhibit signs of hyperthermia, while rabbits and dogs may develop hypothermia.

Chronic administration may lead to physical dependence.

Reproductive/Nursing Safety

Placental transfer of opiates is rapid. In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Morphine appears in maternal milk, but effects on offspring may not be significant when used for short periods. Withdrawal symptoms have occurred however in breastfeeding infants when maternal administration of an opioid-analgesic stopped. Decide whether to accept the risks, discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Overdosage/Acute Toxicity

Overdosage may produce profound respiratory and/or CNS depression in most species. Newborns may be more susceptible to these effects than adult animals. Parenteral doses greater than 100 mg/kg are thought to be fatal in dogs. Other toxic effects can include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Some species such as horses, cats, swine, and cattle may demonstrate CNS excitability (hyperreflexia, tremors) and seizures at high doses or if given rapidly intravenously. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated. Animals should be closely observed as naloxone's effects might diminish before sub-toxic levels of morphine are attained. Mechanical respiratory support should be considered in cases of severe respiratory depression.

Pentobarbital has been suggested as a treatment for CNS excitement and seizures in cats. Extreme caution should be used as barbiturates and narcotics can have additive effects on respiratory depression.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving morphine and may be of significance in veterinary patients:

- **CNS DEPRESSANTS, OTHER** (e.g., **anesthetic agents, antihistamines, phenothiazines, barbiturates, tranquilizers, alcohol**, etc.): May cause increased CNS or respiratory depression when used with morphine
- **DIURETICS**: Opiates may decrease efficacy in CHF patients
- **MONAMINE OXIDASE (MAO) INHIBITORS** (e.g., **amitraz**, possibly **selegiline**): Use MAOI's with morphine with extreme caution as meperidine (a related opiate) is contraindicated in human patients

receiving monamine oxidase (MAO) inhibitors for at least 14 days after receiving MAO inhibitors. Some human patients have exhibited signs of opiate overdose after receiving therapeutic doses of meperidine while taking MAOIs.

- **MUSCLE RELAXANTS, SKELETAL:** Morphine may enhance neuromuscular blockade
- **TRICYCLIC ANTIDEPRESSANTS (clomipramine, amitriptyline, etc.):** Morphine may exacerbate the effects of tricyclic antidepressants
- **WARFARIN:** Opiates may potentiate anticoagulant activity

Laboratory Considerations

- As they may increase biliary tract pressure, opiates can increase plasma amylase and lipase values up to 24 hours following their administration.

Doses

■ DOGS:

For analgesia (acute pain):

- a) 0.5–2 mg/kg IM or SC q3–4 hours. For SLOW IV administration use 10% of IM dose (Hendrix and Hansen 2000)
- b) For post-op pain: 0.25–2 mg/kg IM, SQ; or as a CRI at 0.05–0.2 mg/kg/hr. (Grubb 2007)
- c) 0.5–2.2 mg/kg SC, IM q 4–6h; 0.1–0.2 mg/kg IV q1–2h (Gaynor 2007)
- d) 0.05–1 mg/kg IV q1–4hrs; as a CRI at 0.1–0.5 mg/kg/hr; 0.2–2 mg/kg IM, SC q2–4h; 0.5–1 mg/kg PO q6–8h. (Hansen 2007b)
- e) Using the oral sustained release product: 1.5–3 mg/kg, PO q12h (Hardie 2000) (**Note:** Recent research (KuKanich, Papich et al. 2004) demonstrated that the oral sustained release form of morphine is erratically absorbed in dogs and the authors concluded that it cannot be practically dosed to dogs orally)

Epidural administration for pain control:

- a) 0.1 mg/kg. Dilution may be necessary for accurate measurement. Total volume administered not to exceed 0.3 mL/kg. (Mathews 1999)
- b) 0.1 mg/kg preservative free morphine; duration of action 12–24 hours (Thomas 2000)
- c) Using regular morphine injection: 0.1 mg/kg once; using preservative-free morphine: epidural at 0.1–0.2 mg/kg q8h; spinal at 0.05 mg/kg q8h. (Hansen 2007b)

As a preanesthetic:

- a) 0.1–2 mg/kg SC (Booth 1988a)

For adjunctive treatment of cardiogenic pulmonary edema:

- a) 0.05–1 mg/kg IV q1–4 hours, or 0.1–0.5 mg/kg hr IV infusion, or 0.2–2 mg/kg IM or SC q2–4hr (Hansen 2003a)

For treatment of hypermotile diarrhea:

- a) 0.25 mg/kg (Jones 1985a)

As an antitussive:

- a) 0.1 mg/kg q6–12h SC (Roudebush 1985)

■ CATS:

For analgesia:

- a) For post-op pain: 0.1–0.3 mg/kg IM, SC (Grubb 2007)
- b) 0.05–0.2 mg/kg SC, IM, may cause dysphoria if dose excessive (Carroll 1999)
- c) 0.1–0.4 mg/kg IM, SC q3–6h; concomitant tranquilization recommended (Hendrix and Hansen 2000)
- d) 0.02–0.1 mg/kg IV q1–4hrs; 0.2–0.5 mg/kg IM, SC q3–4h; 0.2–0.5 mg/kg PO q6–8h. (Hansen 2007b)

Epidural administration for pain control:

- a) 0.1 mg/kg preservative free morphine; duration of action 12–24 hours (Thomas 2000)
- b) Using preservative-free morphine: epidural at 0.1–0.2 mg/kg q8h; spinal at 0.05 mg/kg q8h. (Hansen 2007b)

For adjunctive treatment of cardiogenic pulmonary edema:

- a) 0.02–0.1 mg/kg IV q1–4 hours, or 0.2–0.5 mg/kg IM or SC q3–4hr (Hansen 2003a)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 2–5 mg/kg IM or SC q2–4h for sedation and analgesia (Ivey and Morrissey 2000)

■ HORSES: (**Note:** ARCI UCGFS Class 1 Drug)

Note: Narcotics may cause CNS excitement in the horse. Some clinicians recommend pretreatment with acepromazine (0.02–0.04 mg/kg IV), or xylazine (0.3–0.5 mg/kg IV) to reduce the behavioral changes these drugs can cause. **Warning:** Narcotic analgesics can mask the behavioral and cardiovascular clinical signs associated with mild colic.

For analgesia:

- a) 0.1 mg/kg IM q4h; this dose reduces morphine's impact on GI motility, but patients must be observed for problems following morphine use. To cover the excitatory effects of morphine, small doses of acepromazine (0.011–0.022 mg/kg IM, or 5–10 mg/450 kg) are generally included with the morphine injection. (Abrahamsen 2007a)
- b) For epidural: Adult horses: 0.1–0.2 mg/kg using conventional morphine injection (15 mg/mL). Use a freshly opened vial. Suggest diluting with saline to a total volume of 0.04 mL/kg or 20 mL/450kg.
Foals: Using preservative free morphine at 0.1 mg/kg. If no preservative free morphine available, dilute to a volume of 0.2 mL/kg. (Abrahamsen 2007a)
- c) 0.05–0.12 mg/kg IV (Thurmon and Benson 1987)

■ SWINE:

As a preanesthetic/analgesic (prior to chloralose, barbiturate):

- a) 0.2–0.9 mg/kg IM. **Note:** may cause undesirable stimulation. (Booth 1988a)

As an analgesic:

- a) 0.2 mg/kg up to 20 mg total dose IM (Jenkins 1987)

■ SHEEP & GOATS:

As an analgesic:

- a) Up to 10 mg total dose, IM (Jenkins 1987)

Monitoring

- Respiratory rate/depth
- CNS level of depression/excitation
- Blood pressure (especially with IV use)
- Analgesic activity

Client Information

- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision.

Chemistry/Synonyms

The sulfate salt of a natural (derived from opium) occurring opiate analgesic, morphine sulfate occurs as white, odorless, crystals. Solubility: 1 g in 16 mL of water (62.5 mg/mL), 570 mL (1.75 mg/mL) of alcohol. It is insoluble in chloroform or ether. The pH of morphine sulfate injection ranges from 2.5–6.

Morphine sulfate may also be known as morphini sulfas, *Astramorph PF*®, *Avinza*®, *DepoDur*®, *Infumorph*®, *Kadian*®, *MSIR*®, *MS Contin*®, *Oramorph SR*, *RMS*®, and *Roxanol*®.

Storage/Stability/Compatibility

Oral morphine products should be stored in tight, light-resistant containers at room temperature unless otherwise labeled. Morphine injection should be stored at room temperature, protected from light; do not freeze.

Morphine gradually darkens in color when exposed to light; protect from prolonged exposure to bright light. Morphine does not appear to adsorb to plastic or PVC syringes, tubing or bags.

Morphine sulfate has been shown to be physically **compatible** at a concentration of 16.2 mg/L with the following intravenous fluids: Dextrose 2.5%, 5%, 10% in water; Ringer's injection and Lactated Ringer's injection; Sodium Chloride 0.45% and 0.9% for injection. The following drugs have been shown to be physically **incompatible** when mixed with morphine sulfate: aminophylline, chlorothiazide sodium, heparin sodium, meperidine, pentobarbital sodium, phenobarbital sodium, phenytoin sodium, sodium bicarbonate, and thiopental sodium. Morphine sulfate has been demonstrated to be generally physically **compatible** when mixed with the following agents: Atropine sulfate, benzquinamide HCl, butorphanol tartrate, chlorpromazine HCl, diphenhydramine HCl, dobutamine HCl, droperidol, fentanyl citrate, glycopyrrolate, hydroxyzine HCl, metoclopramide, pentazocine lactate, promazine HCl, scopolamine HBr, and succinylcholine chloride.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Morphine Sulfate for Injection: 0.5 mg/mL, 1 mg/mL, 2 mg/mL, 4 mg/mL, 5 mg/mL, 8 mg/mL, 10 mg/mL, 15 mg/mL, 25 mg/mL, 50 mg/mL in amps, vials, syringes, and pre-filled IV bags in sizes that range from 1 mL to 250 mL depending on manufacturer and concentration. (Rx; C-II)

Morphine Sulfate Liposomal Extended-release Injection: 15 mg/mL in 1, 1.5, & 2 mL vials; *DepoDur*® (Endo); (Rx, C-II)

Morphine Sulfate for Injection (preservative-free): 0.5 mg/mL: 2 mL amps, & 10 mL amps and vials; 1 mg/mL: 10 mL amps and vials; 10 mg/mL (200 mg) in 20 mL amps; 25 mg/mL (500 mg) in 20 mL amps; *Infumorph*® (Baxter); *Astramorph PF*® (AstraZeneca); (Rx, C-II)

Morphine Sulfate Soluble Tablets for Injection: 10 mg, 15 mg & 30 mg; generic; (Ranbaxy); (Rx, C-II)

Morphine Sulfate Tablets: 15 mg & 30 mg; generic; (Rx, C-II)

Morphine Sulfate Extended/Controlled Release Tablets: 15 mg, 30 mg, 60 mg, 100 mg & 200 mg; *MS Contin*® (Purdue Frederick); *Oramorph SR*® (aaiPharma); generic; (Rx, C-II)

Morphine Sulfate Extended/Sustained Release Capsules: 20 mg, 30 mg, 50 mg, 60 mg, 80 mg, 90 mg, 100 mg & 120 mg; *Avinza*® (Ligand); *Kadian*® (Alpharma); (Rx, C-II)

Morphine Sulfate Oral Solution: 2 mg/mL in 100 mL, 500 mL and UD 5 mL and 10 mL; 4 mg/mL in 100 mL, 120 mL and 500 mL; 20 mg/mL (concentrate) in 15 mL, 30 mL, 120 mL and 240 mL; *MSIR*® (Purdue Frederick); Morphine Sulfate (Roxane); *Roxanol*®, -T, & -100 (aaiPharma); generic; (Rx, C-II)

Morphine Sulfate Rectal Suppositories: 5 mg, 10 mg, 20 mg, and 30 mg; *RMS*® (Upsher-Smith); generic; (various); (Rx, C-II)

Note: All morphine products are Rx and a Class-II controlled substance. Very accurate record keeping is required as to use and disposition of stock.

MOXIDECTIN

(mox-i-dek-tin) Cydectin®

AVERMECTIN ANTIPARASITIC

Prescriber Highlights

- Avermectin antiparasitic with products approved for cattle, dogs, cats, sheep, & horses
- Contraindications: **DOGS:** Hypersensitive to it. **CATTLE:** Female dairy cattle of breeding age; **HORSES:** Intended for food purposes or in foals younger than 4 months of age
- Adverse Effects: **DOGS** (potentially): Lethargy, vomiting, ataxia, anorexia, diarrhea, nervousness, weakness, increased thirst, & itching. **CATTLE:** Adverse effects minimal. **HORSES:** At labeled doses, appear minimal.
- Apparently safe to use in *mdr1* gene mutation dog breeds at recommended doses

Uses/Indications

In dogs and cats, moxidectin with lufenuron is indicated as a once a month topical preventative for the prevention of heartworm, flea adulticide, ear mites (cats) and treatment for hookworms, roundworms, and whipworms (dogs). It has also been successfully used as a treatment for generalized demodicosis.

In cattle, moxidectin is indicated for the treatment and control of the following internal [adult and fourth stage larvae (L4)] and external parasites: Gastrointestinal roundworms: *Ostertagia ostertagi* (adult and L4, including inhibited larvae), *Haemonchus placei* (adult), *Trichostrongylus axei* (adult and L4), *Trichostrongylus colubriformis* (adult), *Cooperia oncophora* (adult), *Cooperia punctata* (adult), *Bunostomum phlebotomum* (adult), *Oesophagostomum radiatum* (adult), *Nematodirus helvetianus* (adult); Lungworm: *Dictyocaulus viviparus* (adult and L4); Cattle Grubs: *Hypoderma bovis*, *Hypoderma lineatum* Mites: *Chorioptes bovis*, *Psoroptes ovis* (*Psoroptes communis* var. *bovis*); Lice: *Linognathus vituli*, *Haematopinus eurysternus*, *Solenopotes capillatus*, *Damalinea bovis*; Horn flies: *Haematobia irritans*. To control infections and to protect from reinfection from *Ostertagia ostertagi* for 28 days after treatment and from *Dictyocaulus viviparus* for 42 days after treatment.

In sheep, oral moxidectin is indicated for the control of *Haemonchus contortus* (adult and L4), *Teladorsagia circumcincta* & *trifurcata* (adult and L4), *Trichostrongylus colubriformis*, *axei*, & *vitrinus* (adult & L4), *Cooperia curticei* & *oncophora* (adult and L4), *Oesophagostomum columbianum* & *venosum* (adult & L4), and *Nematodirus battus*, *filicollis*, & *spathiger* (adult & L4).

In horses and ponies, moxidectin is indicated for the treatment and control of the following stages of gastrointestinal parasites: Large strongyles: *Strongylus vulgaris* (adults and L4/L5 arterial stages); *Strongylus edentatus* (adults and tissue stages); *Triodontophorus brevicauda* (adults); *Triodontophorus serratus* (adults); Small strongyles (adults and larvae): *Cyathostomum* spp. (adults); *Cylicocyclus* spp. (adults); *Cylicostephanus* spp. (adults); *Gyalocephalus capitatus* (adults); undifferentiated luminal larvae; Encysted cyathostomes: late L3 and L4 mucosal cyathostome larvae; Ascarids: *Parascaris equorum* (adults and L4 larval stages); Pin worms: *Oxyuris equi* (adults and L4 larval stages); Hair worms: *Trichostrongylus axei* (adults); Large-mouth stomach worms: *Habronema muscae* (adults); Horse stomach bots: *Gasterophilus intestinalis* (2nd and 3rd instars). When combined with praziquantel, additional coverage against *Anoplocephala* spp. occurs.

Pharmacology/Actions

The primary mode of action of avermectins like moxidectin is to affect chloride ion channel activity in the nervous system of nematodes and arthropods. The drug binds to receptors that increase membrane permeability to chloride ions. This inhibits the electrical activity of nerve cells in nematodes and muscle cells in arthropods and causes paralysis and death of the parasites. Avermectins also enhance the release of gamma amino butyric acid (GABA) at presynaptic neurons. GABA acts as an inhibitory neurotransmitter and blocks the post-synaptic stimulation of the adjacent neuron in nematodes or the muscle fiber in arthropods. Avermectins are generally not toxic to mammals, since they do not have glutamate-gated chloride channels and these compounds do not readily cross the blood-brain barrier where mammalian GABA receptors occur.

Pharmacokinetics

Minimal information was located. In cattle, the drug apparently has a long duration of plasma residence (14–15 days). After SC injection, approximately 5% of the dose given to the cow can be passed to the suckling calf.

Contraindications/Precautions/Warnings

Dogs: Contraindicated in dogs hypersensitive to it. The manufacturer warns to only use the oral product in dogs tested negative for heartworm infection. Adult heartworms and microfilaria should be removed prior to therapy. If more than two months pass between dosages of this or other once a month heartworm preventative medications, the dog should be tested for heartworm infection before receiving the next dose.

Cattle: Not for use in female dairy cattle of breeding age.

Horses: Not for horses intended for food purposes and is not labeled for use in foals younger than 4 months of age.

Adverse Effects

Dogs: While adverse reactions to this medication apparently occur infrequently, after the injectable product (*ProHeart®6*) was administered to heartworm positive dogs, a low number experienced coughing or cardiopulmonary signs and deaths have occurred (very rarely; 2.5 per 100,000 doses). Additionally, the following adverse reactions may be seen: lethargy, vomiting, ataxia, anorexia, diarrhea, nervousness, weakness, increased thirst, and itching. Studies done in Collies (up to 20X) demonstrated no notable adverse effects. One Collie receiving doses of 30X demonstrated mild signs of depression, ataxia, and salivation.

Cattle: Thus far at labeled doses, adverse effects appear to non-existent or minimal.

Horses: Thus far at labeled doses, adverse effects appear to be nonexistent or minimal. A case report where three foals developed CNS depression and coma after receiving high dosages has been reported. Two of these three animals were less than 2 weeks of age and all received much higher than labeled dosages.

Reproductive/Nursing Safety

Dogs, Cats: Reproductive studies have demonstrated no evidence of adverse effects on fertility, reproductive performance, or offspring.

Cattle & Horses: Reproductive studies performed thus far have demonstrated no evidence of adverse effects on fertility, reproductive performance, or offspring in cattle or horses treated.

Overdosage/Acute Toxicity

Dogs: The drug apparently has a very wide margin of safety in dogs when administered orally. Dosages of up to 300X (1120 mcg/kg) demonstrated little or no effects. Dogs administered inadvertent overdoses during a clinical study treating demodicosis showed

signs of dysorexia, hypersalivation, mydriasis, and fasciculations and ataxia of the pelvic limbs.

There were 172 exposures to moxidectin reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases, 171 were dogs with 42 showing clinical signs and the remaining case was 1 cat that showed clinical signs. Common findings in dogs recorded in decreasing frequency included tremors, ataxia, seizures, vomiting and hyperesthesia. Common findings in cats recorded included recumbency.

Cattle: In studies done on cattle, application of the pour-on solution at 5X the recommended dose for five consecutive days, 10X for two consecutive days and 25X for one day did not produce any significant adverse clinical or pathological effects.

Horses: In one study, three of eight foals given the 3X dose became depressed or ataxic after one treatment. The author has received an anecdotal report of a miniature horse developing seizures after receiving a full tube of *Quest®*.

Drug Interactions

While no specific drug interactions for moxidectin have been reported, the following drug interactions have either been reported or are theoretical in humans or animals receiving ivermectin (a related compound) and may be of significance in veterinary patients:

■ **BENZODIAZEPINES:** Effects may be potentiated by moxidectin; use together not advised in humans

Caution is advised if using other drugs that can inhibit **p-glycoprotein**. Those dogs at risk for MDR1-allele mutation (Collies, Australian Shepherds, Shelties, Long-haired Whippet, etc. “white feet”) should probably not receive moxidectin with the following drugs, unless tested “normal”: Drugs and drug classes involved include:

- AMIODARONE
- CARVEDILOL
- CLARITHROMYCIN
- CYCLOSPORINE
- DILTIAZEM
- ERYTHROMYCIN
- ITRACONAZOLE
- KETOCONAZOLE
- QUINIDINE
- SPIRONOLACTONE
- TAMOXIFEN
- VERAPAMIL

Doses

■ DOGS:

- a) For labeled indications (prevention of heartworm disease, adult fleas, adult and immature hookworms, adult roundworms, and adult whipworms): Recommended minimum dose is 10 mg/kg imidacloprid/2.5 mg/kg moxidectin once a month by topical administration (**Note:** See package insert for specific instructions on application and safety). For dogs 3–9 lb = 0.4 mL; 9.1–20 lb = 1 mL; 20.1–55 lb = 2.5 mL, 55.1–88 lb = 4 mL; dogs over 88 lb should be treated with appropriate combination for their weight. (Label directions; *Advantage Multi® for Dogs*—Bayer)
- b) For scabioicidal therapy: Where *Cydectin®* is available for injection: 0.25 mg/kg SC every 7 days for three treatments. If using oral therapy 0.4 mg/kg PO every 3–4 days for 3–6 weeks. (Foil 2003c)
- c) For generalized demodicosis: 0.2–0.4 mg/kg PO once a day. Clinical cure averages 75 days; parasitic cure averages 112 days. (Merchant 2000)

■ **CATS:**

- a) For labeled indications (prevention of heartworm disease, adult fleas, ear mites, adult and immature hookworms, and adult roundworms: Recommended minimum dose is 10 mg/kg imidacloprid/1 mg/kg moxidectin once a month by topical administration (**Note:** See package insert for specific instructions on application and safety). For cats 2–5 lb = 0.23 mL; 5.1–9 lb = 0.4 mL; 9.1–18 lb = 0.8 mL; cats over 18 lb should be treated with appropriate combination for their weight. (Label directions; *Advantage Multi® for Cats*—Bayer)

■ **CATTLE:**

- a) For labeled indications: 1 mL (5 mg)/10 kg (22 lb) bodyweight applied directly to the hair and skin along the top of the back from the withers to the base of the tail. Application should be made to healthy skin avoiding mange scabs, skin lesions or extraneous foreign matter. (Label Directions; *Cydectin® Pour-On*—Fort Dodge)
- b) 0.2 mg/kg [1 mL for each 110 lb (50 kg) of bodyweight] subcutaneously under the loose skin in front of or behind the shoulder. Needles 1/2–3/4 inch in length and 16–18 gauge are recommended. (Label Directions; *Cydectin® Injection*—Fort Dodge)

■ **SHEEP:**

- a) For labeled indications: 0.2 mg/kg [1 mL per 11 lb (5 kg) bodyweight] PO (drench); *Cydectin® Oral Drench for Sheep*—Fort Dodge)

■ **HORSES:**

- a) For labeled indications using the combination oral gel with praziquantel: Dial in the weight of the animal on the syringe. Administer gel by inserting the syringe applicator into the animal's mouth through the interdental space and depositing the gel in the back of the mouth near the base of the tongue. Once the syringe is removed, the animal's head should be raised to insure proper swallowing of the gel. Horses weighing more than 1250 lb require additional gel from a second syringe. (Label Directions; *Quest® Plus*—Fort Dodge)
- b) For mucosal stages of small strongyles: 400 mcg/kg PO (Lyons and Drudge 2000)

Chemistry/Synonyms

An avermectin-class antiparasitic agent, moxidectin is a semi-synthetic methoxime derivative of nemadectin.

Moxidectin may also be known as CL-301423, *Advantage Multi®*, *ComboCare®*, *Cydectin®*, and *Quest®*.

Storage/Stability

The commercially available injection and the oral drench for sheep should be stored at, or below 77°F (25°C) and protected from light.

The topical solution for cattle should be stored at or below room temperature. Do not allow prolonged exposure to temperatures above 77°F. If product becomes frozen, thaw completely and shake well before using.

The oral gel for horses should be stored at or near room temperature (59°F–86°F); avoid freezing. If product becomes frozen, thaw completely before using. Partially used syringes should have the cap tightly secured.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Moxidectin 0.5% (5 mg/mL) Pour-On for Cattle in 500 mL, 1 L, 2.5 L, 5 L, and 10 L containers; *Cydectin®* (Fort Dodge); (OTC). Approved for use in cattle; not to be used in veal calves. No meat or milk withdrawal times required, but FDA has established tolerances of 50 ppb and 200 ppb for parent moxidectin in muscle and liver, respectively, for cattle.

Moxidectin 10 mg/mL Injectable Solution in 200 mL and 500 mL; *Cydectin® Injectable Solution* (Fort Dodge); (OTC). Approved for cattle. Not to be used in female dairy cattle of breeding age, veal calves, and calves less than 8 weeks of age. Meat withdrawal = 21 days.

Moxidectin 1 mg/mL Injectable Solution in 1 L and 4 L; *Cydectin® Oral Drench for Sheep* (Fort Dodge); (OTC). Approved for sheep. Not to be used in female sheep providing milk for human consumption. Meat withdrawal = 7 days.

Moxidectin Oral Gel containing 20 mg/mL in 11.3 g syringes (sufficient to treat one 1150 lb horse); *Quest®* (Fort Dodge); (OTC). Approved for use in horse or ponies not intended for food purposes.

Oral Gel containing 20 mg/mL moxidectin and 125 mg/mL of praziquantel in 11.6 g syringes (sufficient to treat one 1150 lb horse); *Quest Plus®* (Fort Dodge), *ComboCare® Equine Oral Gel* (Farnam); (OTC). Approved for use in horse or ponies not intended for food purposes.

Moxidectin 1% (10 mg/mL) and Imidacloprid 10% (100 mg/mL) Topical Solution in 3—0.23mL tubes, 6—0.4mL tubes & 6—0.8mL tubes; *Advantage Multi® for Cats* (Bayer); (Rx). Approved for use on cats 9 weeks of age or greater, and more than 2 lb body weight.

Moxidectin 2.5% (25 mg/mL) and Imidacloprid 10% (100 mg/mL) Topical Solution in 6—0.4mL tubes, 6—1mL tubes, 6—2.5 mL tubes, & 6—4mL tubes; *Advantage Multi® for Dogs* (Bayer); (Rx). Approved for use on dogs 7 weeks of age or greater, and more than 3 lb body weight.

HUMAN-LABELED PRODUCTS: None

MYCOBACTERIAL CELL WALL FRACTION IMMUNOMODULATOR

(my-koe-bak-tear-ee-al) Regressin®-V, Equimune® I.V.
IMMUNOSTIMULANT

Prescriber Highlights

- Biologic used as a locally infiltrated injection for immunotherapy treatment of mixed mammary tumor & mammary adenocarcinomas in dogs
- In horses, used for immunotherapy treatment of sarcoids (local infiltration), ERCD (IV) or as an aid in the treatment of equine metritis caused by *Streptococcus zooepidemicus* (IV, IU)
- Adverse effects include: Transient fever, depression, decreased appetite, localized pain. Hypersensitivity & systemic inflammatory reactions possible.
- Efficacy for systemic use is not well established

Uses/Indications

Mycobacterial cell wall fraction immunomodulator is commercially available as three products with veterinary labeling, *Regressin*®-V, *Equimune*®-IV and *Settle*®. *Regressin*®-V is labeled as a locally infiltrated injection for immunotherapy treatment of mixed mammary tumor and mammary adenocarcinomas in dogs, and for immunotherapy treatment of sarcoids in horses. *Equimune*®-IV is labeled for use in horses only as an immunotherapeutic agent for the treatment of Equine Respiratory Disease Complex (ERDC). *Settle*® is labeled as an aid in the treatment of equine metritis caused by *Streptococcus zooepidemicus* (IV, IU) in horses.

Although not labeled indications, *Equimune*®-IV has reportedly been used in horses as an adjuvant for EPM treatment and as an adjuvant for herpesvirus vaccines when injected IM at a separate site from the vaccine. Documentation of efficacy for these uses was not located.

Pharmacology/Actions

Mycobacterial fractionated compounds require a functional immune system for efficacy. They have a non-specific immune stimulatory primarily on cell-mediated immune mechanisms and macrophage activation. Interleukin-1 release from macrophages is thought to be the primary mediator for their actions.

Pharmacokinetics

No information was located.

Contraindications/Precautions/Warnings

These drugs should not be used in patients with prior hypersensitivity to mycobacterial cell wall compounds or those with mycobacterial infections.

The manufacturer warns that patients receiving cortisone or ACTH may not respond to treatment; in case of an anaphylactic reaction, administer epinephrine.

Adverse Effects

Horses: Adverse effects include fever, drowsiness and diminished appetite for 1–2 days after injection. Local infiltrations can cause pain and tenderness at injection site. Anaphylaxis and severe respiratory inflammatory reactions have also been reported.

Dogs: Adverse effects include fever, drowsiness and diminished appetite for 1–2 days after injection. Local infiltrations can cause pain and tenderness at injection site. Later necrosis and draining may occur. Anaphylaxis or hypersensitivity reactions are possible.

Reproductive/Nursing Safety

The manufacturer states that *Regressin*®-V and *Equimune*®-I.V. are safe to use in pregnant mares. No other information was located.

Overdosage/Acute Toxicity

No information was located.

Drug Interactions

■ **CORTICOSTEROIDS, ACTH, IMMUNOSUPPRESSIVE DRUGS** (e.g., cyclosporine): May reduce the effectiveness of mycobacterial cell wall immunostimulants

Laboratory Considerations

None identified

Doses**■ DOGS:**

- Using *Regressin*®-V for immunotherapy of mixed mammary tumor and mammary adenocarcinoma: Using no larger than a 20-gauge needle, infiltrate entire tumor and a small region of adjacent and underlying tissue. Dosage varies with tumor size, but 1 mL should be considered a minimum dose. Be certain the emulsion is mixed thoroughly and inject quickly as emulsion can separate rapidly (see Stability information for more information on mixing.) As pain may occur, additional anesthetics or analgesics may be used. Tumors may be treated once, 2–4 weeks before surgery. If surgery is not to be used, repeat treatment every 1–3 weeks. If no response after 4 treatments, discontinue. (Label information; *Regressin*®-V—Bioniche)

■ HORSES:

- Using *Regressin*®-V for immunotherapy of sarcoids: Large pedunculated sarcoids should be de-bulked by partial excision prior to treatment. Using no larger than a 20-gauge needle, infiltrate entire tumor and a small region of adjacent and underlying tissue. Dosage varies with tumor size, but 1 mL should be considered a minimum dose. Be certain the emulsion is mixed thoroughly and inject quickly as emulsion can separate rapidly (see Stability information for more information on mixing.) As pain may occur, additional anesthetics or analgesics may be used. Repeat treatment every 1–3 weeks. If no response after 4 treatments, discontinue. (Label information; *Regressin*®-V—Bioniche)
- Using *Equimune*® I.V. as an immunotherapeutic agent for the treatment of Equine Respiratory Disease Complex (ERDC): 1.5 mL (one syringe) IV into the jugular vein. May be repeated in 1–3 weeks. (Label information; *Equimune*® I.V.—Bioniche)
- Using *Settle*® as an aid in the treatment of equine metritis caused by *Streptococcus zooepidemicus*: Intravenous use: 1.5 mL (one syringe) IV into the jugular vein during the early estrus period. Or administer via intrauterine instillation: Dilute 1.5 mL of *Settle*® in sterile LRS, normal saline, water for injection or semen extender to provide a final volume of 25–50 mL. Aseptically administer the diluted solution into the uterus using a sterile catheter. (Label information; *Settle*®—Bioniche)

Monitoring

- Clinical Efficacy (tumor size, metritis improvement, or respiratory infection improvement)
- Adverse Effects (fever, local reactions, appetite)

Client Information

- Intratumoral injection may cause pain or tenderness at the injection site. Tumors may drain or become necrotic indicating effectiveness; if this occurs and is bothersome, contact veterinarian for further instructions on management.
- Treated animals may be depressed, develop fever, or have reduced appetite for a few days after treatment; if these persist or are severe, contact veterinarian

Chemistry/Synonyms

Regressin®-V, *Equimune*®-I.V. and *Settle*® are oil-in-water emulsions containing purified cell wall fractions obtained from Mycobacteria (species not described) that are non-pathogenic. Concentration is not listed for either product. *Regressin*®-V also contains procaine HCl 0.2% w/v as a local anesthetic and a green tracking dye solution (not identified) 0.1% w/v used to indicate area infiltrated.

Mycobacterial cell wall fraction may also be known as mycobacterial cell wall extract, bacillus Calmette-Guerin, or BCG, *Equimmune*®, *Regressin*®, and *Settle*®.

Storage/Stability

These products should be stored refrigerated (2–7°C), but not frozen. Unused product from vials not labeled for multi-dose use should be discarded after use.

The emulsion “breaks” upon standing and the product must be re-emulsified before administration. To re-emulsify to a milky appearance, shake vial, roll syringe between hands, or heat in hot water (150°F, 65°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Mycobacterial Cell Wall Fraction Immunomodulator for IV Injection in 1.5 mL single use vials and 4.5 mL multi-dose vials; *Equimmune*® I.V. (Bioniche). Labeled for use in horses.

Mycobacterial Cell Wall Fraction Immunomodulator for IV injection of Intrauterine instillation in 1.5 mL single use vials; *Settle*® (Bioniche). Contains gentamicin as a preservative. Labeled for use in horses.

Mycobacterial Cell Wall Fraction Immunomodulator for Tumor Infiltration in 10 mL vials; *Regressin*®-V (Bioniche). Also contains procaine and a green dye. Labeled for use in horses and dogs.

Note: These products are USDA-licensed biologics and are not FDA-approved products. *Equimmune*® I.V. and *Regressin*®-V are not to be used in food producing animals. The label for *Settle*® states that it should not be administered to horses within 21 days of slaughter.

HUMAN-LABELED PRODUCTS: None

MYCOPHENOLATE MOFETIL

(my-koh-fen-oh-layt) Cellcept®, MMF

IMMUNOSUPPRESSANT

Prescriber Highlights

- ▶ Immunosuppressive drug that may be useful for treating dogs with IMHA, glomerulonephritis, myasthenia gravis, pemphigus foliaceus or inflammatory bowel disease in dogs; potentially useful in cats, but no information located on safety or efficacy
- ▶ Very limited experience in veterinary medicine
- ▶ Gastrointestinal effects (diarrhea, vomiting, anorexia) most likely adverse effects & can be severe
- ▶ Treatment may be very expensive

Uses/Indications

While there has been very limited experience using mycophenolate in veterinary medicine, it potentially could be useful in the treatment of a variety of autoimmune diseases, including immune-mediated hemolytic anemia (IMHA), myasthenia gravis, glomerulonephritis, and pemphigus foliaceus. While mycophenolate has been suggested for use in treating inflammatory bowel disease in dogs, the drug's primary adverse effects in dogs are gastritis, diarrhea, and intestinal inflammation. Mycophenolate is also used in anti-rejection protocols for organ transplants in animals.

In humans, although it is used “off label” for a variety of autoimmune disease indications, the drug is only labeled for use to prevent transplant rejection.

Pharmacology/Actions

Mycophenolate mofetil (MMF) is a prodrug that must be converted (hydrolyzed) *in vivo* to mycophenolic acid (MPA) for it to be pharmacologically active. MPA non-competitively, but reversibly, inhibits inosine monophosphate dehydrogenase (IMPDHA). This is the rate-limiting enzyme in *de novo* synthesis of guanosine nucleotides. As T- and B-cells are dependent on *de novo* synthesis of purines (e.g., guanosine) and unlike other cells cannot use salvage pathways, proliferative responses of T- and B-cells are inhibited and suppression of B-cell formation of antibodies occur. Via its effects, MPA can inhibit leukocyte recruitment to inflammatory sites and allotransplant tissues.

Pharmacokinetics

After oral administration mycophenolate mofetil is absorbed, but limited bioavailability studies in dogs have shown both a wide inter-patient and inter-dose variation. One study done in a single dog showed bioavailabilities of 54%, 65%, and 87% after doses of 10, 15, and 20 mg/kg of MMF were administered (Lupu, McCune et al. 2006). In humans, oral bioavailability averages 94%; food reduces peak levels of MPA by up to 40%. After absorption, MMF is rapidly hydrolyzed to mycophenolic acid.

In a study in dogs comparing mycophenolic acid's (MPA) pharmacokinetic parameters with its pharmacodynamic effects on inosine monophosphate dehydrogenase activity in lymphocytes (Langman, Shapiro et al. 1996), volume of distribution at steady-state was approximately 5 L/kg, but there was wide inter-patient variability (± 4.5). Elimination half-life for MPA was about 8 hours (± 4 hours). Mycophenolic acid is primarily excreted in the urine, both unchanged (approximately 5%) and as the glucuronide metabolite (approximately 90%). In this study, the authors concluded that the pharmacokinetic/pharmacodynamic profile of MMF in dogs suggests that an every 8-hour dosing schedule would be required for optimization of immunosuppressive efficacy.

Contraindications/Precautions/Warnings

Do not use in patients with documented hypersensitivity reactions to mycophenolate. Patients with severe renal dysfunction may require dosage adjustment.

Intravenous mycophenolate must be administered over at least two hours; it is not to be given as an IV bolus or via rapid IV infusion.

For humans, mycophenolate has a “black box” warning regarding potential increased risk for lymphoma associated with its use.

Adverse Effects

Because of the limited numbers of veterinary patients who have received this drug, the adverse effect profile is not well established. The primary adverse effects reported in dogs thus far include diarrhea, vomiting, anorexia, lethargy/reduced activity, lymphopenia, and increased rates of dermal infections. Because of the drug's immunosuppressive actions, increased systemic infection and malignancy rates are possible.

A study (Chanda, Sellin et al. 2002) comparing adverse effects in dogs with mycophenolate mofetil capsules and mycophenolate sodium enteric-coated tablets demonstrated significantly greater occurrences and severity of diarrhea, weight loss and hypo-activity in the dogs that received the sodium salt enteric-coated tablets.

In humans, the most common adverse effects include GI effects (constipation, diarrhea, nausea, vomiting) and headache. Hypertension and peripheral edema occur in about 30% of pa-

tients. Leukopenia has been reported in 25–45% of patients taking the medication. Other effects that occur more rarely include: GI bleeding, severe neutropenia, cough, confusion, tremor, infection and malignant lymphoma (0.4–1%).

Reproductive/Nursing Safety

At doses significantly lower than those used in humans, increased resorptions and malformations were noted in rabbits and rats; it is recommended that the drug be avoided, if at all possible, during pregnancy.

Mycophenolic acid is distributed in rat milk. It is unknown if it is safe to use during nursing.

Overdosage/Acute Toxicity

In oral acute studies performed in mice and monkeys, no deaths occurred in dosages up to 4,000 mg/kg and 1,000 mg/kg, respectively. In small animals, acute GI disturbances could be expected. Treat supportively, if required.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving mycophenolate mofetil and may be of significance in veterinary patients:

- **ACYCLOVIR:** Increased serum concentrations of acyclovir and the phenolic glucuronide of mycophenolic acid
- **ANTACIDS (aluminum or magnesium containing):** Decreased absorption of mycophenolate; separate dosing by at least 2 hours
- **ASPIRIN (or other salicylates):** Potentially increased concentrations of free mycophenolic acid
- **AZATHIOPRINE:** Increased risk for bone marrow suppression; use together not recommended in humans
- **IRON (oral):** Decreased absorption of mycophenolate; separate dosing by at least 2 hours
- **PROBENECID:** Potentially increased serum levels of mycophenolic acid and the phenolic glucuronide of mycophenolic acid
- **VACCINES (live virus):** May be less effective; avoid use

Laboratory Considerations

No issues noted

Doses

- **DOGS:**
 - a) For IMHA: 12–17 mg/kg PO once daily or divided twice daily. Given with prednisolone (at 2 mg/kg q12–24h). Dogs also received ranitidine and sucralfate in the study. (Nielsen, Niessen et al. 2005)
 - b) Limited use has shown a beneficial response in dogs with IMHA, myasthenia gravis or glomerulonephritis: 12–17 mg/kg PO once daily or divided twice daily. Given with prednisone (at 2.2 mg/kg q12–24h). (Macintire 2006d)
 - c) For adjunctive treatment of glomerulonephritis: 10–20 mg/kg PO q12h. Immunosuppressive treatment is controversial. Other immunosuppressive drugs suggested include: glucocorticoids, cyclophosphamide, azathioprine, and cyclosporine. Trial of single drug therapy for 3–4 weeks recommended. (Labato 2006)
 - d) For pemphigus foliaceus: 22–39 mg/kg/day divided into 3 daily doses. Success rates (limited use) of approximately 50%; most dogs require glucocorticoids to control signs. (Rosenkrantz 2004)
 - e) For pemphigus foliaceus: 15 mg/kg PO twice daily. Dose is anecdotal at this time. Appears well tolerated. (Morris 2004)

Monitoring

- Efficacy
- CBC, renal and hepatic function, serum electrolytes; baseline and periodically (frequency depending on reason for treatment)
- Gastrointestinal effects (weight, client's report)

Client Information

- Preferably give on an empty stomach; if vomiting or lack of appetite occurs, give with food to see if it improves
- Because of concerns that this drug can cause birth defects, the manufacturer recommends that tablets or capsules not be crushed, split, or opened.
- If diarrhea persists or is severe, contact veterinarian

Chemistry/Synonyms

Mycophenolate mofetil occurs as a white or almost white, crystalline powder. It is practically insoluble in water and sparingly soluble in alcohol.

Mycophenolate mofetil may also be known as: RS-61443 or MMF. International trade names include: *CellCept*®, *Cellmune*®, *Imuxgen*®, *Munotras*®, *Mycepr*®, *Myfortic*®, and *Refrat*®.

Storage/Compatibility

Mycophenolate mofetil tablets and capsules should be stored between 15–30°C and protected from light.

Mycophenolate mofetil powder for oral suspension should be stored between 15–30°C; preferably at 25°C. Once reconstituted with 94 mL of water it may be stored at room temperature or in the refrigerator; do not freeze. Unused drug should be discarded after 60 days.

The injectable product should be stored between 15–30°C; preferably at 25°C. Each vial should be reconstituted with 14 mL of 5% dextrose injection; final volume is approximately 15 mL. Gently agitate to dissolve the powder. For human use, the manufacturer recommends further diluting with dextrose 5% to a concentration of 6 mg/mL for IV administration. This would be an additional 70 mL of dextrose 5% per vial. Mycophenolate injection should not be mixed or given with any other medication or diluent. It is recommended to administer within 6 hours of dilution. The drug must be administered over at least two hours and is not to be given as an IV bolus or via rapid IV infusion.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Mycophenolate Mofetil Capsules: 250 mg; *CellCept*® (Roche); (Rx)

Mycophenolate Mofetil Tablets: 500 mg; *CellCept*® (Roche); (Rx)

Mycophenolate Mofetil Powder for Oral Suspension: 200 mg/mL in 225 mL bottles; *CellCept*® (Roche); (Rx)

Mycophenolate Mofetil Lyophilized Powder for Injection: 500 mg in 20 mL vials; *CellCept*® (Roche); (Rx)

Mycophenolate is also available as the sodium salt in oral, delayed-release tablets in 180 mg and 360 mg strengths. Trade name is *Myfortic*® (Novartis); (Rx). It does not appear that this dosage form will be useful for veterinary patients.

NALOXONE HCL

(nal-ox-one) Narcan®

ANTIDOTE; OPIATE ANTAGONIST

Prescriber Highlights

- ▶ **Injectable opiate antagonist**
- ▶ **Contraindications:** Hypersensitivity to it. **Caution:** Preexisting cardiac abnormalities or opioid dependent
- ▶ **Reversal effect may last for a shorter time than opioid effect; monitor & re-dose as needed**

Uses/Indications

Naloxone is used in veterinary medicine almost exclusively for its opiate reversal effects, but the drug is being investigated for treating other conditions (e.g., septic, hypovolemic or cardiogenic shock). Naloxone may also be employed as a test drug to see if endogenous opiate blockade will result in diminished tail chasing or other self-mutilating behaviors. It, potentially, could be useful for treating overdoses of clonidine or the CNS effects of benzodiazepines (ivermectin?), but more research is necessary before recommending its use.

Pharmacology/Actions

Naloxone is considered a pure opiate antagonist and it has no analgesic activity. The exact mechanism for its activity is not understood, but it is believed that the drug acts as a competitive antagonist by binding to the *mu*, *kappa*, and *sigma* opioid receptor sites. The drug apparently has its highest affinity for the *mu* receptor.

Naloxone reverses the majority of effects associated with high-dose opiate administration (respiratory and CNS depression). In dogs, naloxone apparently does not reverse the emetic actions of apomorphine.

Naloxone may be useful in treating adverse effects associated with overdoses of propoxyphene, pentazocine, buprenorphine and loperamide, but larger naloxone doses may be required.

Naloxone has other pharmacologic activity at high doses, including effects on dopaminergic mechanisms (increases dopamine levels) and GABA antagonism.

Pharmacokinetics

Naloxone is only minimally absorbed when given orally as it is rapidly destroyed in the GI tract. Much higher doses are required if using this route of administration for any pharmacologic effect. When given IV, naloxone has a very rapid onset of action (usually 1–2 minutes). If given IM, the drug generally has an onset of action within 5 minutes of administration. The duration of action usually persists from 45–90 minutes, but may act for up to 3 hours.

Naloxone is distributed rapidly throughout the body with high levels found in the brain, kidneys, spleen, skeletal muscle, lung, and heart. The drug also readily crosses the placenta.

Naloxone is metabolized in the liver, principally via glucuronidative conjugation, with metabolites excreted into the urine. In humans, the serum half-life is approximately 60–100 minutes.

Contraindications/Precautions/Warnings

Naloxone is contraindicated in patients hypersensitive to it. It should be used cautiously in animals that have preexisting cardiac abnormalities or that may be opioid dependent. The veterinary manufacturer of the product once marketed for veterinary use states to use the drug "... cautiously in animals who have received exceedingly

large doses of narcotics...it may produce an acute withdrawal syndrome and smaller doses should be employed." (Package Insert; P/M® Naloxone HCl Injection—Mallinckrodt)

Adverse Effects

At usual doses, naloxone is relatively free of adverse effects in non-opioid dependent patients.

Because the duration of action of naloxone may be shorter than that of the narcotic being reversed, animals that are being treated for opioid intoxication or with clinical signs of respiratory depression should be closely monitored as additional doses of naloxone and/or ventilatory support may be required.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **A** (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

It is not known whether the drug is excreted in maternal milk. Use caution when administering to nursing patients.

Overdosage/Acute Toxicity

Naloxone is considered a very safe agent with a very wide margin of safety, but very high doses have initiated seizures (secondary to GABA antagonism?) in a few patients.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving naloxone and may be of significance in veterinary patients:

- **OPIOID PARTIAL-AGONISTS** (e.g., **butorphanol**, **pentazocine**, or **nalbuphine**): Naloxone may also antagonize the effects these agents (respiratory depression, analgesia). It should not be relied upon to treat respiratory depression caused by **buprenorphine**.
- **CLONIDINE**: Naloxone may reduce the hypotensive and bradycardic effects of clonidine; potentially useful for clonidine overdoses
- **YOHIMBINE**: Naloxone may increase the CNS effects of yohimbine (anxiety, tremors, nausea, palpitations) and increase plasma cortisol levels

Doses

■ DOGS & CATS:

For opioid reversal:

- a) 0.002–0.02 mg/kg IV or IM; duration of effect 0.5–1 hour (Bednarski 1989)
- b) Dogs: 0.04 mg/kg IV, IM or SC (Package Insert; P/M® Naloxone HCl Injection—Mallinckrodt), (Kirk 1989)
- c) Cats: 0.05–0.1 mg/kg IV (Muir and Swanson 1989)
- d) 0.02–0.04 mg/kg IV (Morgan 1988)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) For opioid reversal in rodents: 0.01–0.1 mg/kg SC or IP as needed (Huerkamp 1995)
- b) Rabbits: 0.005–0.1 mg/kg IM or IV (Ivey and Morrissey 2000)
- c) Hamsters, Gerbils, Mice, Rats, Guinea pigs, Chinchillas: 0.01–0.1 mg/kg SC, IP (Adamcak and Otten 2000)

■ **HORSES:** (Note: ARCI UCGFS Class 3 Drug)

For opioid reversal:

- 0.01–0.022 mg/kg to reverse sedative and excitatory effects of narcotic agonists (Clark and Becht 1987)
- 0.01 mg/kg IV to limit increases in locomotor activity secondary to narcotic agonists (Muir 1987)
- 0.01–0.02 mg/kg IV (Robinson 1987)

Monitoring

- Respiratory rate/depth
- CNS function
- Pain associated with opiate reversal

Client Information

- Should be used with direct professional supervision only

Chemistry/Synonyms

An opiate antagonist, naloxone HCl is structurally related to oxymorphone. It occurs as a white to slightly off-white powder with a pK_a of 7.94. Naloxone is soluble in water and slightly soluble in alcohol. The pH ranges of commercially available injectable solutions are from 3–4.5.

Naloxone HCl may also be known as: N-allylnoroxymorphone hydrochloride; cloridrato de naloxona, EN-15304, naloxoni hydrochloridum and *Narcan*®.

Storage/Stability/Compatibility

Naloxone HCl for injection should be stored at room temperature (15–30°C) and protected from light.

Sterile water for injection is the recommended diluent for naloxone injection. When given as an IV infusion, either D5W or normal saline should be used. Naloxone HCl injection **should not** be mixed with solutions containing sulfites, bisulfites, long-chain or high molecular weight anions or any solutions at alkaline pH.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Naloxone HCl Injection: 0.4 mg/mL in 1 mL amps, syringes and 1, 2, and 10 mL vials; *Narcan*® (DuPont Pharm.); generic; (Rx)

Naloxone HCl Neonatal Injection: 0.02 mg/mL in 2 mL vials; generic; (Rx)

NALTREXONE HCL

(nal-trex-ohne) Trexan®, ReVia®

OPIATE ANTAGONIST

Prescriber Highlights

- Oral opiate antagonist that might be useful in determining if adverse behaviors have a significant endorphin component & for the short-term treatment of same
- **Contraindications:** Patients physically dependent on opiate drugs, in hepatic failure, or with acute hepatitis. Caution: hepatic dysfunction or who have had a history of allergic reaction to naltrexone or naloxone.
- **Adverse Effects:** Relatively free of adverse effects. Potentially: Abdominal cramping, nausea & vomiting, nervousness, insomnia, joint or muscle pain, skin rashes, & pruritus. Dose-dependent hepatotoxicity is possible.
- May cause withdrawal clinical signs in physically dependent patients
- Expensive

Uses/Indications

Naltrexone might be useful in determining if adverse behaviors (e.g., self-mutilating or tail-chasing) in dogs or cats have a significant endorphin component. Its relative expense and other more accepted treatments have largely supplanted the use of this drug in animals for treatment of behavioral disorders.

Pharmacology/Actions

Naltrexone is an orally available narcotic antagonist. It competitively binds to opiate receptors in the CNS, thereby preventing both endogenous opiates (e.g., endorphins) and exogenously administered opiate agonists or agonist/antagonists from occupying the site. Naltrexone may be more effective in blocking the euphoric aspects of the opiates and less effective at blocking the respiratory depressive or miotic effects.

Naltrexone may also increase plasma concentrations of luteinizing hormone (LH), cortisol, and ACTH. In dogs with experimentally-induced hypovolemic shock, naltrexone (like naloxone) given IV in high dosages increased mean arterial pressure, cardiac output, stroke volume, and left ventricular contractility.

Pharmacokinetics

In humans, naltrexone is rapidly and nearly completely absorbed, but undergoes a significant first-pass effect as only 5–12% of a dose reaches the systemic circulation. Naltrexone circulates throughout the body and CSF levels are approximately 30% of those found in plasma. Only about 20–30% is bound to plasma proteins. It is unknown whether naltrexone crosses the placenta or enters milk. Naltrexone is metabolized in the liver primarily to 6-beta-naltrexol, which has some opiate blocking activity. Naltrexone's metabolites are eliminated primarily via the kidney. In humans, serum half-life of naltrexone is about 4 hours and about 13 hours for 6-beta-naltrexol.

Contraindications/Precautions/Warnings

Naltrexone is contraindicated in patients physically dependent on opiate drugs, in hepatic failure, or with acute hepatitis. The benefits of the drug versus its risks should be weighed in patients with hepatic dysfunction or with a history of allergic reaction to naltrexone or naloxone.

Adverse Effects

At usual doses, naltrexone is relatively free of adverse effects in non-opioid dependent patients. Some human patients have developed abdominal cramping, nausea and vomiting, nervousness, insomnia, joint or muscle pain, skin rashes, and pruritus. Dose-dependent hepatotoxicity has been described in humans on occasion.

Naltrexone will block the analgesic, antidiarrheal, and antitussive effects of opiate agonist or agonist/antagonist agents. Withdrawal clinical signs may be precipitated in physically dependent patients.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *D* for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) Very high doses have caused increased embryotoxicity in some laboratory animals. It should be used during pregnancy only when the benefits outweigh any potential risks.

Naltrexone enters into milk of humans and sheep. Use caution when administering to nursing patients.

Overdosage/Acute Toxicity

Naltrexone appears to be relatively safe even after very large doses. The LD₅₀ in dogs after subcutaneous injection has been reported to be 200 mg/kg. Oral LD₅₀'s in species tested range from 1.1 g/kg in mice to 3 g/kg in monkeys (dogs or cats not tested). Deaths at these doses were a result of respiratory depression and/or tonic-clonic seizures. Massive overdoses should be treated using gut-emptying protocols when warranted and giving supportive treatment.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving naltrexone and may be of significance in veterinary patients:

- **OPIOID PARTIAL-AGONISTS** (e.g., **butorphanol**, **pentazocine**, or **nalbuphine**): Naloxone may also antagonize the effects these agents (respiratory depression, analgesia).
- **CLONIDINE**: Naltrexone may reduce the hypotensive and bradycardic effects of clonidine
- **YOHIMBINE**: Naltrexone may increase the CNS effects of yohimbine (anxiety, tremors, nausea, palpitations) and increase plasma cortisol levels

Laboratory Considerations

- Naltrexone reportedly does not interfere with TLC, GLC, or HPLC methods of determining **urinary opiates**, or quinine, but can interfere with some enzymatic assays
- Naltrexone may cause increases in **hepatic function tests** (e.g., AST, ALT) (see Adverse Effects above).

Doses

■ DOGS:

As adjunctive therapy in behavior disorders:

- a) For tail chasing or excessive licking: First give 0.01 mg/kg SC of naloxone to determine if narcotic antagonists may be effective, if so give naltrexone PO at 1–2 mg/kg daily. Long-term therapy may be required. (Crowell-Davis 1992)
- b) 2–5 mg/kg, PO once daily (Line 2000)
- c) 1–2.2 mg/kg, PO q8–12h (Crowell-Davis 1999)

For the adjunctive treatment of acral pruritic dermatitis:

- a) 2.2 mg/kg, PO once daily for one-month trial. Some dogs exhibit drowsiness and minor changes in behavior. 50–60% of patients have benefited. Expense is of concern. (Rosychuck 1991)

■ CATS:

As adjunctive therapy in behavior disorders:

- a) 25–50 mg/cat PO q24h. **Note:** has a bitter taste (Crowell-Davis 1999)

Monitoring

- Efficacy
- Liver enzymes if using very high dose with prolonged therapy

Client Information

- Stress the importance of compliance with prescribed dosing regimen
- Additional behavior modification techniques may be required to alleviate clinical signs

Chemistry/Synonyms

A synthetic opiate antagonist, naltrexone HCl occurs as white crystals having a bitter taste. 100 mg are soluble in one mL of water.

Naltrexone may also be known as EN-1639A, *ReVia*® and *Vivitrol*®.

Storage/Stability/Compatibility

Naltrexone tablets should be stored at room temperature in well-closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Naltrexone HCl Tablets: 50 mg; *ReVia*® (Duramed); generic; (Rx)

Naltrexone HCl Suspension Extended-Release Injection: 380 mg/vial in single-use vials; *Vivitrol*® (Alkermes, Inc.); (Rx)

NANDROLONE DECANOATE

(*nan-droe-lone*) Deca-Durabolin®

PARENTERAL ANABOLIC STEROID

Prescriber Highlights

- ▶ **Injectable anabolic steroid**; may be useful to stimulate erythropoiesis or to stimulate appetite
- ▶ **Contraindications:** Hepatic dysfunction, hypercalcemia, history of myocardial infarction, pituitary insufficiency, prostate carcinoma, mammary carcinoma, benign prostatic hypertrophy, & during the nephrotic stage of nephritis
- ▶ **Adverse Effects:** Sodium, calcium, potassium, water, chloride, & phosphate retention; hepatotoxicity, behavioral (androgenic) changes, & reproductive abnormalities (oligospermia, estrus suppression)
- ▶ **Known teratogen**
- ▶ **Drug Interactions**
- ▶ **C-III Controlled Substance**

Uses/Indications

The principle use of nandrolone in veterinary medicine has been to stimulate erythropoiesis in patients with certain anemias (e.g., secondary to renal failure, aplastic anemias). It has also been suggested for use as an appetite stimulant.

Pharmacology/Actions

Nandrolone exhibits similar actions as other anabolic agents. In the presence of adequate protein and calories, anabolic steroids promote body tissue building processes and can reverse catabolism. As these agents are either derived from or closely related to testosterone, the anabolics have varying degrees of androgenic effects. Endogenous testosterone release may be suppressed by inhibiting luteinizing hormone (LH). Large doses can impede spermatogenesis by negative feedback inhibition of FSH.

Anabolic steroids can stimulate erythropoiesis. The mechanism for this effect may occur by stimulating erythropoietic stimulating factor. Anabolics can cause nitrogen, sodium, potassium, and phosphorus retention and decrease the urinary excretion of calcium. Many veterinary and human clinicians feel that nandrolone is clinically superior to other anabolics in its ability to stimulate erythropoiesis. It is believed that nandrolone may enhance red cell counts by directly stimulating red cell precursors in the bone marrow, increasing red cell 2,3-diphosphoglycerate and erythropoietin production in the kidney.

Pharmacokinetics

No specific information was located for this agent. It is generally recommended for both small animals and humans to be dosed on a weekly basis.

Contraindications/Precautions/Warnings

No specific recommendations were located for this agent in veterinary species.

In humans, anabolic agents are contraindicated in patients with hepatic dysfunction, hypercalcemia, patients with a history of myocardial infarction (can cause hypercholesterolemia), pituitary insufficiency, prostate carcinoma, in selected patients with breast carcinoma, benign prostatic hypertrophy, and during the nephrotic stage of nephritis.

Adverse Effects

Potential (from human data) adverse reactions of the anabolic agents in dogs and cats include: sodium, calcium, potassium, water, chloride, and phosphate retention; hepatotoxicity, behavioral (androgenic) changes, and reproductive abnormalities (oligospermia, estrus suppression).

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **X** for use during pregnancy (*Studies in animals or humans demonstrate fetal abnormalities or adverse reaction; reports indicate evidence of fetal risk. The risk of use in pregnant women clearly outweighs any possible benefit.*) Anabolic steroids can cause masculinization of the fetus.

It is not known whether anabolic steroids are excreted in maternal milk. Because of the potential for serious adverse reactions in nursing offspring, decide whether to discontinue nursing or the drug.

Overdosage/Acute Toxicity

No information was located for this specific agent. In humans, sodium and water retention can occur after overdosage of anabolic steroids. It is suggested to treat supportively and monitor liver function should an inadvertent overdose be administered.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nandrolone and may be of significance in veterinary patients:

- **ANTICOAGULANTS (warfarin):** Anabolic agents as a class may potentiate the effects of anticoagulants; monitoring of INR and dosage adjustment of the anticoagulant (if necessary) are recommended
- **CORTICOSTEROIDS, ACTH:** Anabolics may enhance the edema that can be associated with ACTH or adrenal steroid therapy
- **INSULIN:** Diabetic patients receiving insulin may need dosage adjustments if anabolic therapy is added or discontinued; anabolics may decrease blood glucose and decrease insulin requirements

Laboratory Considerations

- Concentrations of **protein bound iodine (PBI)** can be decreased in patients receiving androgen/anabolic therapy, but the clinical significance of this is probably not important
- Androgen/anabolic agents can decrease amounts of **thyroxine-binding globulin** and decrease **total T₄** concentrations and increase **resin uptake of T₃ and T₄**; free thyroid hormones are unaltered and, clinically, there is no evidence of dysfunction.
- Both **creatinine** and **creatinine excretion** can be decreased by anabolic steroids
- Anabolic steroids can increase the urinary excretion of **17-ketosteroids**
- Androgenic/anabolic steroids may alter **blood glucose** levels.
- Androgenic/anabolic steroids may suppress **clotting factors II, V, VII, and X**.
- Anabolic agents can affect **liver function tests** (BSP retention, SGOT, SGPT, bilirubin, and alkaline phosphatase)

Doses■ **DOGS:**

For adjunctive treatment of chronic idiopathic myelofibrosis:

- a) Prednisolone at 2–3 mg/kg PO once daily for 3–4 weeks, then every other day with a tapering of the dose as the anemia resolves. Nandrolone decanoate may be used at 2 mg/kg IM weekly for 3 weeks. If anemia does not respond to initial treatments, azathioprine at 2 mg/kg PO every other day can be given. (Raskin 2006)

For disuse muscle atrophy secondary to immobilization:

- a) 1.5 mg/kg IM once weekly from the day of surgery/immobilization for up to 8 weeks. (Yun, Lim et al. 2005)

For treatment of anemia in patients with chronic renal failure:

- a) 1–1.5 mg/kg IM once weekly; may require 2–3 months to achieve beneficial effects (Polzin and Osborne 1985)
- b) 5 mg/kg IM (maximum of 200 mg/week) every 2–3 weeks (Ross et al. 1988)

For treatment of metabolic and endocrine anemias:

- a) 5 mg/kg IM once weekly (maximum of 200 mg); most resolve with correction of underlying disease process (Maggio-Price 1988)

For aplastic anemia:

- a) 1–3 mg/kg IM weekly (Weiss 1986)

As an appetite stimulant:

- a) 5 mg/kg IM (max. 200 mg/week) weekly (Macy and Ralston 1989)

■ CATS:

For FeLV-induced anemia or as a general bone marrow stimulant:

- a) 10–20 mg IM once weekly (is of questionable benefit) (Maggio-Price 1988)

For chronic anemia secondary to feline cardiomyopathy:

- a) 50 mg IM weekly (Harpster 1986)

■ REPTILES:

To reduce protein catabolism in renal disease of lizard species:

- a) 1 mg/kg IM every 7–28 days (de la Navarre 2003a)

Monitoring

- Androgenic side effects
- Fluid and electrolyte status, if indicated
- Liver function tests if indicated
- Red blood cell count, indices, if indicated
- Weight, appetite

Client Information

- Because of the potential for abuse of anabolic steroids by humans, this agent is a controlled (C-III) drug. It should be kept in a secure area and out of the reach of children.

Chemistry/Synonyms

An injectable anabolic steroid, nandrolone decanoate occurs as a white, to creamy white, crystalline powder. It is odorless or may have a slight odor and melts between 33–37°C. Nandrolone decanoate is soluble in alcohol and vegetable oils and is practically insoluble in water. The commercially available injectable products are generally solutions dissolved in sesame oil.

Nandrolone decanoate may also be known as: nortestosterone decanoate, or nortestosterone decylate.

Storage/Stability/Compatibility

Nandrolone decanoate for injection should be stored at temperatures less than 40°C and preferably between 15–30°C (59–86°F); protect from freezing and light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Nandrolone Decanoate Injection (in oil): 100 mg/mL in 2 mL multi-dose vials & 200 mg/mL in 1 mL vials; generic; (Watson); (Rx, C-III)

NAPROXEN

(na-*prox*-en) Naprosyn®, Aleve®

NONSTEROIDAL ANTIINFLAMMATORY AGENT

Prescriber Highlights

- NSAID; use largely superseded by newer, less GI-toxic NSAIDs in dogs & by other NSAIDs in horses as the equine product is no longer marketed (in USA)
- Contraindications: Active GI ulcers or history of hypersensitivity to the drug. Relatively Contraindicated: Hematologic, renal or hepatic disease. Caution: History of gastric ulcers, heart failure
- Because of difficulty in accurately dosing, adverse effects, & safer alternatives, usually not used in dogs
- Adverse Effects: Relatively uncommon in HORSES: Possible GI (distress, diarrhea, ulcers), hematologic (hypoproteinemia, decreased hematocrit), renal (fluid retention), & CNS (neuropathies) DOGS: GI ulcers & perforation, renal effects (nephritis/nephrotic syndrome), & hepatic (increased liver enzymes) effects
- Drug Interactions

Uses/Indications

The manufacturer lists the following indications: "...for the relief of inflammation and associated pain and lameness exhibited with myositis and other soft tissue diseases of the musculoskeletal system of the horse." (Package Insert; *Equiproxen*®—Syntex). It has also been used as an antiinflammatory/analgesic in dogs for the treatment of osteoarthritis and other musculoskeletal inflammatory diseases (see adverse reactions below).

Pharmacology/Actions

Like other NSAIDs, naproxen exhibits analgesic, antiinflammatory, and antipyretic activity probably through its inhibition of cyclooxygenase with resultant impediment of prostaglandin synthesis.

Pharmacokinetics

In horses, the drug is reported to have a 50% bioavailability after oral dosing and a half-life of approximately 4 hours. Absorption does not appear to be altered by the presence of food. It may take 5–7 days to see a beneficial response after starting treatment. Following a dose, the drug is metabolized in the liver. It is detectable in the urine for at least 48 hours in the horse after an oral dose.

In dogs, absorption after oral dosing is rapid and bioavailability is between 68–100%. The drug is highly bound to plasma proteins. The average half-life in dogs is very long at 74 hours.

In humans, naproxen is highly bound to plasma proteins (99%). It crosses the placenta and enters milk in levels of about 1% of those found in serum.

Contraindications/Precautions/Warnings

Naproxen is relatively contraindicated in patients with a history of or preexisting hematologic, renal, or hepatic disease. It is contraindicated in patients with active GI ulcers, or with a history of hypersensitivity to the drug. It should be used cautiously in patients with a history of GI ulcers, or heart failure (may cause fluid retention). Animals suffering from inflammation secondary to concomitant infection, should receive appropriate antimicrobial therapy.

Adverse Effects

Adverse effects are apparently uncommon in horses. The possibility exists for GI (distress, diarrhea, ulcers), hematologic (hypoproteinemia, decreased hematocrit), renal (fluid retention), and CNS (neuropathies) effects.

Reports of GI ulcers and perforation associated with naproxen have occurred in dogs. Dogs may also be overly sensitive to the adverse renal (nephritis/nephrotic syndrome) and hepatic effects (increased liver enzymes) of naproxen. Because of the apparently very narrow therapeutic index and the seriousness of the potential adverse reactions that can be seen in dogs, many clinicians feel that the drug should not be used in this species.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) In studies in rodents and in limited studies in horses, no evidence of teratogenicity or adverse effects in breeding performance have been detected following the use of naproxen. Weigh the potential benefits of therapy against the potential risks of its use in pregnant animals.

Most NSAIDs are excreted in maternal milk. Naproxen appears at approximately 1% of maternal serum concentration.

Overdosage/Acute Toxicity

There is very limited information regarding acute overdoses of this drug in humans and domestic animals. The reported oral LD₅₀ in dogs is >1000 mg/kg.

One report of a dog that received 5.6 mg/kg for 7 days has been published (Gilmour and Walshaw 1987). The dog presented with clinical signs of melena, vomiting, depression, regenerative anemia, and pale mucous membranes. Laboratory indices of note included neutrophilia with a left shift, BUN of 66 mg/dl, serum creatinine of 2.1 mg/dl, serum protein to albumin of 4.0:2.1 g/dl. The dog recovered following treatment with fluids/blood, antibiotics, vitamin/iron supplementation, oral antacids, and cimetidine.

There were 236 exposures to naproxen reported to the ASPCA Animal Poison Control Center (APCC; www.apcc.aspc.org) during 2005–2006. In these cases 213 were dogs with 35 dogs showing clinical signs and the remaining 22 cases were cats with 4 cats showing clinical signs. Common findings in dogs recorded in decreasing frequency included vomiting, bloody diarrhea, melena, ataxia and diarrhea. Common findings in cats recorded in decreasing frequency included vomiting, azotemia, bloody vomitus, facial twitching and hypothermia.

As with any NSAID, overdosage can lead to gastrointestinal and renal effects. Decontamination with emetics and/or activated charcoal is appropriate. For doses where GI effects are expected, the use of gastrointestinal protectants is warranted. If renal effects are also expected, fluid diuresis should be considered. Supportive treatment should be instituted as necessary. Monitor electrolyte and fluid balance carefully and manage renal failure using established guidelines.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving naproxen and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES** (gentamicin, amikacin, etc.): Increased risk for nephrotoxicity
- **ANTICOAGULANTS** (heparin, LMWH, warfarin): Increased risk for bleeding possible
- **ASPIRIN**: When aspirin is used concurrently with naproxen, plasma levels of naproxen could decrease and an increased likelihood of GI adverse effects (blood loss) could occur. Concomitant administration of aspirin with naproxen cannot be recommended.
- **BISPHOSPHONATES** (alendronate, etc.): May increase risk for GI ulceration
- **CORTICOSTEROIDS**: Concomitant administration with NSAIDs may significantly increase the risks for GI adverse effects
- **FUROSEMIDE**: Naproxen may reduce the saluretic and diuretic effects of furosemide
- **HIGHLY PROTEIN BOUND DRUGS** (e.g., phenytoin, valproic acid, oral anticoagulants, other antiinflammatory agents, salicylates, sulfonamides, and the sulfonylurea antidiabetic agents): Because naproxen is highly bound to plasma proteins (99%), it potentially could displace other highly bound drugs; increased serum levels and duration of actions may occur. Although these interactions are usually of little concern clinically, use together with caution.
- **METHOTREXATE**: Serious toxicity has occurred when NSAIDs have been used concomitantly with methotrexate; use together with extreme caution.
- **PROBENECID**: May cause a significant increase in serum levels and half-life of naproxen.

Doses

■ DOGS:

Note: Because of the difficulty in accurately dosing naproxen and its potential for adverse effects, the use of this drug in dogs should only be considered when approved and safer NSAIDs have been ineffective.

- a) 2 mg/kg PO every other day (q48h) (Hansen 2003b), (Hardie, Lascelles et al. 2003), (Hardie and Grauer 2007)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: For septic arthritis pain; inflammation: 2.4 mg/mL in drinking water for 21 days (Ivey and Morrissey 2000)

■ HORSES: (Note: ARCI UCGFS Class 4 Drug)

- a) 5 mg/kg by slow IV, then 10 mg/kg, PO (top dressed in feed) twice daily for up to 14 days or 10 mg/kg, PO (top dressed in feed) twice daily for up to 14 consecutive days. (Package Insert; Equiproxen®—Syntex Animal Health; **Note:** No longer commercially available)
- b) 10 mg/kg PO daily (Trumble and Kawcak 2003)

Monitoring

- Analgesic/antiinflammatory efficacy
- GI: appetite, feces (occult blood, diarrhea)
- PCV (packed cell volume), hematocrit if indicated or on chronic therapy
- WBC's if indicated or on chronic therapy

Client Information

- Notify veterinarian if clinical signs of GI distress (anorexia, vomiting, diarrhea, black feces, or blood in stool) occur, or if animal becomes depressed.

Chemistry/Synonyms

Naproxen is a propionic acid derivative, having similar structure and pharmacologic profiles as ibuprofen and ketoprofen. It is a white to off-white crystalline powder with an apparent pK_a of 4.15. It is practically insoluble in water and freely soluble in alcohol. The sodium salt is also available commercially for human use.

Naproxen may also be known as: naproxeneum, RS-3540, RS-3650, *Aleve*®, *Anaprox*®, *EC-Naprosyn*®, *Midol*®, *Naprelan*® and *Naprosyn*®.

Storage/Stability/Compatibility

Naproxen should be stored in well-closed, light resistant containers at room temperature. Temperatures above 40° C (104°F) should be avoided.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

None; the equine product is no longer marketed in the USA.

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Naproxen Tablets: 200 mg (220 mg naproxen sodium), 250 mg (275 mg naproxen sodium), 375 mg, 500 mg (550 mg naproxen sodium); *Naprosyn*® (Roche); *Anaprox*® and *Anaprox DS*® (Roche); *Aleve*® & *Midol*® *Extended Relief* (Bayer); generic; (Rx and OTC)

Naproxen Delayed/Controlled-release Tablets: 375 mg) & 500 mg; *EC-Naprosyn*® (Roche); *Naprelan*® (Blansett Pharmacal); generic; (Rx)

Naproxen Oral Suspension: 125 mg/5 mL in 15 mL, 20 mL, 473 mL & 500 mL; *Naprosyn*® (Roche); generic; (Rx)

NARCOTIC (OPIATE) AGONIST ANALGESICS, PHARMACOLOGY OF

Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and in other smooth muscle.

Opiate receptors are further broken down into five main subgroups. *Mu* receptors are found primarily in the pain regulating areas of the brain. They are thought to contribute to the analgesia, euphoria, respiratory depression, physical dependence, miosis, and hypothermic actions of opiates. *Kappa* receptors are located primarily in the deep layers of the cerebral cortex and spinal cord. They are responsible for analgesia, sedation, and miosis. *Sigma* receptors are thought to be responsible for the dysphoric effects (struggling, whining), hallucinations, respiratory and cardiac stimulation, and mydriatic effects of opiates. *Delta* receptors, located in the limbic areas of the CNS, and epsilon receptors have also been described, but their actions have not been well explained at this time.

The morphine-like agonists (morphine, meperidine, oxycodone) have primary activity at the *mu* receptors, with some activity possible at the *delta* receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal effects (constipation/defecation). Secondary pharmacologic effects include, *CNS*: euphoria, sedation, and confusion. *Cardiovascular*:

bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. *Urinary*: Increased bladder sphincter tone can induce urinary retention.

Various species may exhibit contradictory effects from these agents. For example, horses, cattle, swine, and cats may develop excitement after morphine injections and dogs may defecate after morphine. These effects are in contrast to the expected effects of sedation and constipation. Dogs and humans may develop miosis, while other species (especially cats) may develop mydriasis. For more information see the individual monographs for each agent.

N-BUTYLSCOPOLAMMONIUM BROMIDE (HYOSCINE BUTYLBROMIDE)

(en-*byoo*-tel-skoe-*pahl*-ah-moe-nee-um *broe*-mide)

Buscaban®

QUATERNARY AMMONIUM ANTISPASMODIC & ANTICHOLINERGIC

Prescriber Highlights

- Injectable anticholinergic used in horses for treating colic associated with spasmodic colic, flatulent colic, & simple impactions
- Shorter acting than atropine; only labeled for a single (one-time) dose IV
- Not for use in patients with ileus or when decreased GI motility may be harmful
- Adverse effects include transient tachycardia, pupil dilation, decreased secretions & dry mucous membranes

Uses/Indications

N-butylscopolammonium bromide injection is indicated (per the label) for control of abdominal pain (colic) associated with spasmodic colic, flatulent colic, and simple impactions in horses. It may also be of benefit as an aid to performing rectal exams in horses.

Pharmacology/Actions

N-butylscopolammonium reduces gastrointestinal peristalsis and rectal pressure via its anti-cholinergic actions by competitively inhibiting muscarinic receptors on smooth muscle. N-butylscopolammonium has shorter duration of action than atropine.

Pharmacokinetics

Limited information is available for horses. After an intravenous dose, the drug is eliminated within 48 hours in urine and feces equally. Estimated elimination half-life is approximately 6 hours.

Contraindications/Precautions

N-butylscopolammonium is labeled as contraindicated in horses with impaction colics associated with ileus or those with glaucoma.

This medication is not to be used in horses intended for food purposes.

The manufacturer has not studied the safety of IM administration.

Adverse Effects

Labeled adverse effects include transient tachycardia and decreased borborygmal sounds that last for approximately 30 minutes after IV dosing. Transient pupil dilation can be noted. Other effects include decreased secretions and dry mucous membranes.

Because this drug can cause increases in heart rate, heart rate cannot be used as a valid pain indicator for 30 minutes after injection.

When used for labeled indications, a lack of response may indicate a more serious problem that may require surgery or more aggressive care (White 2005b).

Reproductive/Nursing Safety

As no data is available to document safety, the manufacturer does not recommend use in nursing foals or pregnant or lactating mares.

Overdosage/Acute Toxicity

Dosages up to 10X (3 mg/kg) were administered to horses as part of pre-approval studies. Clinical effects noted included dilated pupils (returned to normal in 4–24 hours), tachycardia (returned to normal within 4 hours) and dry mucous membranes (returned to normal in 1–2 hours). Gut motility was inhibited, but returned to baseline within 4 hours and normal feces were seen within 6 hours. Two of the four horses treated at 10X dosage developed mild signs of colic which resolved without further treatment.

Drug Interactions

The following drug interactions have either been reported or are theoretical in animals receiving N-butylscopolammonium bromide and may be of significance in veterinary patients:

- **ATROPINE or other anticholinergic agents:** May cause additive effects if used with N-butylscopolammonium
- **METOCLOPRAMIDE and other drugs that have cholinergic-like actions on the GI tract:** These drugs and N-butylscopolammonium may counteract one another's actions on GI smooth muscle

Laboratory Considerations

No specific concerns noted.

Doses

■ HORSES:

For labeled indications:

- a) 0.3 mg/kg (30 mg or 1.5 mL per 100 kg of body weight) via slow IV, one time (Label Dosage; *Buscopan*®—BI)

Monitoring

- Heart rate (**Note:** heart rate cannot be used as indicator for pain for the first 30 minutes after administration)
- GI motility via gut sounds and feces output

Client Information

- Because an accurate patient assessment must be performed prior to the use of this medication and intravenous administration and subsequent monitoring are required, this drug should only be administered by veterinarians

Chemistry/Synonyms

N-butylscopolammonium bromide, a derivative of scopolamine, is a synthetic, quaternary ammonium antispasmodic-anticholinergic agent. It occurs as a white crystalline substance that is soluble in water.

N-butylscopolammonium bromide may also be known as: butylscopolamine bromide, hysocine butylbromide, hysocine N-butylbromide, scopolamini butylbromidum, hyoscini butylbromidum, *Buscopan*® or *Buscapina*®.

Storage/Stability

The commercially available injection should be stored at room temperature (15–30°C).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

N-butylscopolammonium bromide Injection: 20 mg/mL in 50 mL multi-dose vials, *Buscopan*® (Boehringer Ingelheim); (Rx). Approved for use in horses.

In the UK, *Buscopan Compositum*® (BI) is commercially available. This product contains metamizole (a form of dipyron) 500 mg/mL and hyoscine butylbromide (synonym for N-butylscopolammonium Br) 4 mg/mL. It is labeled for use in horses, cattle and dogs.

HUMAN-LABELED PRODUCTS:

None in the USA. There are several products with the trade name *Buscopan*® or *Buscapina*® available in many countries. Refer to actual product labels as ingredients and concentrations may vary.

NEOMYCIN SULFATE

(nee-o-mye-sin) Biosol®, Neomix®

AMINOGLYCOSIDE ANTIBIOTIC

Prescriber Highlights

- Aminoglycoside antibiotic usually used orally (gut “sterilization”) or in topical formulations
- Contraindications: Oral: Hypersensitive to aminoglycosides, intestinal blockage; rabbits
- Adverse Effects: Parenteral use can be very toxic (nephrotoxic) & is not recommended. Chronic use can lead to GI superinfections. Rarely, oral neomycin may cause ototoxicity, nephrotoxicity, severe diarrhea, & intestinal malabsorption
- Minimal amounts absorbed via GI (if intact)

Uses/Indications

Because neomycin is more nephrotoxic and less effective against several bacterial species than either gentamicin or amikacin, its use is generally limited to topical formulations for skin, eyes, and ears, oral treatment of enteric infections, to reduce microbe numbers in the colon prior to colon surgery, and oral or enema administration to reduce ammonia-producing bacteria in the treatment of hepatic encephalopathy. Doses for parenteral administration are listed below, but should be used only with extreme caution due to the drug's toxic potential.

Pharmacology/Actions

Neomycin has a mechanism of action and spectrum of activity (primarily gram-negative aerobes) similar to the other aminoglycosides, but in comparison to either gentamicin or amikacin, it is significantly less effective against several species of gram-negative organisms, including strains of *Klebsiella*, *E. coli*, and *Pseudomonas*. However, most strains of neomycin-resistant bacteria of these species remain susceptible to amikacin. More detailed information on the aminoglycosides mechanism of action and spectrum of activity is outlined in the amikacin monograph.

Pharmacokinetics

Approximately 3% of a dose of neomycin is absorbed after oral or rectal (retention enema) administration, but this can be increased if gut motility is slowed or if the bowel wall is damaged. Therapeutic levels are not attained in the systemic circulation after oral administration.

After IM administration, therapeutic levels can be attained with peak levels occurring within 1 hour of dosing. The drug apparently distributes to tissues and is eliminated like the other aminoglycosides (refer to Amikacin monograph for more details). Orally administered neomycin is nearly all excreted unchanged in the feces.

Contraindications/Precautions/Warnings

Oral neomycin is contraindicated in the presence of intestinal obstruction or if the patient is hypersensitive to aminoglycosides. Chronic usage of oral aminoglycosides may result in bacterial or fungal superinfections.

Because aminoglycosides can cause irreversible ototoxicity, they should be used with caution in “working” dogs.

Aminoglycosides should be used with caution in patients with neuromuscular disorders (e.g., myasthenia gravis) due to their neuromuscular blocking activity.

Because aminoglycosides are eliminated primarily through renal mechanisms, they should be used cautiously, preferably with serum monitoring and dosage adjustment in neonatal or geriatric animals.

Aminoglycosides are generally considered contraindicated in rabbits/hares, as they adversely affect the GI flora balance in these animals.

Adverse Effects

Refer to the amikacin monograph for more information regarding these topics with parenteral neomycin; however, parenterally administered neomycin is much more nephrotoxic than is amikacin.

Rarely, oral neomycin may cause ototoxicity, nephrotoxicity, severe diarrhea, and intestinal malabsorption.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: A (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Neomycin is excreted in cow's milk following a single IM injection. If used orally, it is unlikely neomycin poses significant systemic risk to nursing offspring, but may negatively alter gut flora and cause diarrhea.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oral neomycin and may be of significance in veterinary patients:

■ **DIGOXIN:** Oral neomycin with orally administered digoxin may result in decreased absorption. Separating the doses of the two medications may not alleviate this effect. Some human patients (<10%) metabolize digoxin in the GI tract and neomycin may increase serum digoxin levels in these patients. It is recommended that enhanced monitoring be performed if oral neomycin is added or withdrawn from the drug regimen of a patient stabilized on a digitalis glycoside.

■ **METHOTREXATE:** Absorption may be reduced by oral neomycin but is increased by oral kanamycin (found in *Amforal*®)

■ **OTOTOXIC, NEPHROTOXIC DRUGS:** Although only minimal amounts of neomycin are absorbed after oral or rectal administration, the concurrent use of other ototoxic or nephrotoxic drugs with neomycin should be done with caution

■ **PENICILLIN VK (oral):** Oral neomycin should not be given concurrently with oral penicillin VK as malabsorption of the penicillin may occur

■ **WARFARIN:** Oral neomycin may decrease the amount of vitamin K absorbed from the gut; this may have ramifications for patients receiving oral anticoagulants

Refer to the amikacin monograph for more information regarding drug interactions with parenteral neomycin.

Laboratory Considerations

No specific concerns noted

Doses

■ DOGS:

For treatment of hepatic encephalopathy:

- 22 mg/kg PO three to four times daily (Hardy 1989)
- For emergency treatment of hepatic encephalopathy secondary to portosystemic shunts: Following evacuation enema instill 10–20 mg/kg neomycin sulfate diluted in water. Oral neomycin not recommended. (Cornelius and Bjorling 1988)
- 15 mg/kg as an enema every 6 hours after a cleansing enema or 10–20 mg/kg, PO every 6 hours. May be used with lactulose. (Johnson 1986)

For GI tract infections:

- For campylobacteriosis: 20 mg/kg PO q12h (Willard 2003c)

For systemic therapy (**Caution:** Very nephrotoxic):

- 3.5 mg/kg IV, IM or SC q8h (Kirk 1989)

■ CATS:

For treatment of hepatic encephalopathy:

- Secondary to portosystemic shunts: 10–20 mg/kg PO two times a day. May be used in combination with lactulose or in cleansing enemas. (Center, Hornbuckle, and Scavelli 1986)
- 22 mg/kg q8h PO (Cornelius, Bartges et al. 2000)
- Lactulose at 0.5–1 mg/kg PO q8h with or without neomycin at 20 mg/kg PO q8–12h. (Marks 2004a)

For GI tract infections: For campylobacteriosis:

- 20 mg/kg PO q12h (Willard 2003c)

For systemic therapy (**Caution:** Very nephrotoxic):

- 3.5 mg/kg IV, IM or SC q8h (Kirk 1989)

■ FERRETS:

For susceptible enteric infections:

- 10–20 mg/kg, PO twice to four times daily (Williams 2000)

■ RODENTS, SMALL MAMMALS:

Note: Contraindicated in rabbits/hares

- Chinchillas: 15 mg/kg, PO once daily. Gerbils: 100 mg/kg, PO once daily, Guinea Pigs: 8 mg/kg, PO once daily. Hamsters: 100 mg/kg, PO once daily, or 0.5 mg/mL in drinking water. Mice, Rats: 50 mg/kg, PO once daily (Adamcak and Otten 2000)

■ CATTLE:

For oral administration to treat susceptible enteral infections:

- 4–7.5 g/day PO divided 2–4 times daily at regular intervals. Calves: 2–3 g/day, PO divided 2–4 times daily at regular intervals. Doses are not standardized; use for general guidance only. (Brander, Pugh, and Bywater 1982)

- b) 10–20 mg/kg q12h (general guideline only). (Jenkins 1986)
- c) 7–12 mg/kg, PO q12h (Howard 1986)
- d) Feed at levels of 70–140 g/ton of feed or mix the appropriate dose in the drinking water which will be consumed by animals in 12 hours to provide 11 mg/kg or mix with reconstituted milk replacers to provide 200–400 mg/gallon. (Label directions; *Neomix Ag*® 325—Upjohn)

■ HORSES:

For oral administration to treat susceptible enteral infections:

- a) Adults: 4–7.5 g/day PO divided 2–4 times daily at regular intervals. Foals: 2–3 g/day PO divided 2–4 times daily at regular intervals. Doses are not standardized; use for general guidance only. (Brander, Pugh, and Bywater 1982)
- b) 5–15 mg/kg PO once daily (Robinson 1987)

For intrauterine infusion:

- a) Neomycin alone: 3–4 grams. Combination of neomycin (2 gram) and procaine penicillin G (3,000,000 IU), Combination of Neomycin (1 gram) and Polymyxin B (40,000 IU), Furaladone (600 mg) and penicillin G (Sodium or potassium, 3,000,000–5,000,000 IU). Little science is available for recommending doses, volume infused, frequency, diluents, etc. Most intrauterine treatments are commonly performed every day or every other day for 3–7 days. (Perkins 1999)

■ SWINE:

For oral administration to treat susceptible enteral infections:

- a) Young pigs: 0.75–1 g/day, PO divided 2–4 times daily at regular intervals. Doses are not standardized; use for general guidance only. (Brander, Pugh, and Bywater 1982)
- b) 7–12 mg/kg, PO q12h (Howard 1986)

■ SHEEP & GOATS:

For oral administration to treat susceptible enteral infections:

- a) Lambs: 0.75–1 g/day PO divided 2–4 times daily at regular intervals. Doses are not standardized; use for general guidance only. (Brander, Pugh, and Bywater 1982)
- b) Feed at levels of 70–140 g/ton of feed or mix the appropriate dose in the drinking water which will be consumed by animals in 12 hours to provide 11 mg/kg or mix with reconstituted milk replacers to provide 200–400 mg/gallon. (Label directions; *Neomix Ag*® 325—Upjohn)

■ BIRDS:

For bacterial enteritis:

- a) Chickens, turkeys, ducks: Feed at levels of 70–140 g/ton of feed or mix the appropriate dose in the drinking water which will be consumed by animals in 12 hours to provide 11 mg/kg (Label directions; *Neomix Ag*® 325—Upjohn)

■ SNAKES:

For susceptible infections:

- a) For bacterial gastritis: gentamicin 2.5 mg/kg IM every 72 hours with oral neomycin 15 mg/kg plus oral live lactobacillus (Burke 1986)

Monitoring

For oral use:

- Clinical efficacy
- Systemic and GI adverse effects with prolonged use.

For parenteral use: Refer to Amikacin monograph

Client Information

- Clients should understand that the potential exists for severe toxicity (nephrotoxicity, ototoxicity) developing from this medication when used parenterally.

Chemistry/Synonyms

An aminoglycoside antibiotic obtained from *Streptomyces fradiae*, neomycin is actually a complex of three separate compounds, neomycin A (neamine; inactive), neomycin C, and neomycin B (framycetin). The commercially available product almost entirely consists of the sulfate salt of neomycin B. It occurs as an odorless or almost odorless, white to slightly yellow, hygroscopic powder or cryodesiccated solid. It is freely soluble in water and very slightly soluble in alcohol. One mg of pure neomycin sulfate is equivalent to not less than 650 Units. Oral or injectable (after reconstitution with normal saline) solutions of neomycin sulfate have a pH from 5–7.5.

Neomycin sulfate may also be known as: fradiomycin sulfate, neomycin sulphate, or neomycini sulfas, *Neo-325*®, *Neo-fradin*®, *Neo-Sol 50*®, and *Neovet*®.

Storage/Stability

Neomycin sulfate oral solution should be stored at room temperature (15–30°C) in tight, light-resistant containers. Unless otherwise instructed by the manufacturer, oral tablets/boluses should be stored in tight containers at room temperature. The sterile powder should be stored at room temperature and protected from light.

In the dry state, neomycin is stable for at least 2 years at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Neomycin Sulfate Oral Liquid: 200 mg/mL (140 mg neomycin base/mL); generic; (OTC). Depending on labeling approved for use in cattle, swine, sheep, goats, turkeys, laying hens, and broilers. Check labels for slaughter withdrawals; may vary with product. General withdrawal times (when used as labeled): Cattle = 1 day; Sheep = 2 days and swine and goats = 3 days. Withdrawal period has not been established in pre-ruminating calves. Do not use in calves to be processed for veal. A milk discard period has not been established in lactating dairy cattle. Do not use in female dairy cattle 20 months of age or older.

Neomycin Sulfate Soluble Powder: 325 grams/lb: *Neo-325*® Soluble Powder (Bimeda); *Neovet*® 325/100 & *NeoVet*® 325 AG Grade (includes turkey label); (AgriPharm) *Neo-Sol 50*® (Alpharma); (OTC). Approved for use in Cattle and goats (not veal calves), swine, sheep, goats and turkeys (some products). Check labels for slaughter withdrawals; may vary with product. General slaughter withdrawal times (when used as labeled): Cattle = 1 day; Turkeys = 0 days; Sheep = 2 days; Swine and Goats = 3 days.

HUMAN-LABELED PRODUCTS:

Neomycin Sulfate Tablets: 500 mg; generic; (Rx)

Neomycin Sulfate Oral Solution: 25 mg/mL in 480 mL; *Neo-fradin*® (Pharma-Tek); (Rx)

NEOSTIGMINE BROMIDE NEOSTIGMINE METHYLSULFATE

(nee-oh-stig-meen) Prostigmin®

PARASYMPATHOMIMETIC (CHOLINERGIC)

Prescriber Highlights

- ▶ Parasympathomimetic used to initiate peristalsis, empty the bladder, & stimulate skeletal muscle contractions. Also for diagnosis & treatment of myasthenia gravis & treatment of non-depolarizing neuromuscular blocking agents (curare-type) overdose; has been used for treating massive ivermectin overdoses in cats
- ▶ Contraindications: Peritonitis, mechanical intestinal or urinary tract obstructions, late stages of pregnancy, hypersensitivity to this class of compounds, or if treated with other cholinesterase inhibitors
- ▶ Adverse Effects: Cholinergic in nature & dose related (nausea, vomiting, diarrhea, excessive salivation & drooling, sweating, miosis, lacrimation, increased bronchial secretions, bradycardia or tachycardia, cardiospasm, bronchospasm, hypotension, muscle cramps & weakness, agitation, restlessness, or paralysis)
- ▶ Cholinergic crisis & myasthenic crisis must not be confused

Uses/Indications

Neostigmine is indicated for rumen atony, initiating peristalsis, emptying the bladder, and stimulating skeletal muscle contractions in cattle, horses, sheep, and swine (Package insert; *Stiglyn® 1:500-P/M*—Mallinckrodt). It has been used in the diagnosis and treatment of myasthenia gravis and in treating non-depolarizing neuromuscular blocking agents (curare-type) overdoses in dogs. Neostigmine has also been used to treat massive ivermectin overdoses in cats.

Pharmacology/Actions

Neostigmine competes with acetylcholine for acetylcholinesterase. As the neostigmine-acetylcholinesterase complex is hydrolyzed at a slower rate than that of the acetylcholine-enzyme complex, acetylcholine will accumulate with a resultant exaggeration and prolongation of its effects. These effects can include increased tone of intestinal and skeletal musculature, stimulation of salivary and sweat glands, bronchoconstriction, ureter constriction, miosis and bradycardia. Neostigmine also has a direct cholinomimetic effect on skeletal muscle.

In horses, neostigmine may decrease jejunal activity and delay gastric emptying. Its use in treating colon impactions and ileus is controversial.

Pharmacokinetics

Information on the pharmacokinetics of neostigmine in veterinary species was not located. In humans, neostigmine bromide is poorly absorbed after oral administration with only 1–2% of the dose absorbed. Neostigmine effects on peristaltic activity in humans begin within 10–30 minutes after parenteral administration and can persist for up to 4 hours.

Neostigmine is 15–25% bound to plasma proteins. It has not been detected in human milk nor would it be expected to cross the placenta when given at usual doses.

In humans, the half-life of the drug is approximately one hour. It is metabolized in the liver and hydrolyzed by cholinesterases to 3-OH PTM, which is weakly active. When administered parenterally, approximately 80% of the drug is excreted in the urine within 24 hours, with 50% excreted unchanged.

Contraindications/Precautions/Warnings

Neostigmine is contraindicated in patients with peritonitis, mechanical intestinal or urinary tract obstructions, in animals hypersensitive to this class of compounds, or treated with other cholinesterase inhibitors.

Use neostigmine with caution in patients with epilepsy, peptic ulcer disease, bronchial asthma, cardiac arrhythmias, hyperthyroidism, vagotonia, or megacolon.

Adverse Effects

Adverse effects of neostigmine are dose-related and cholinergic in nature. See overdose section below.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Because it is ionized at physiologic pH, neostigmine would not be expected to be excreted in maternal milk.

Overdosage/Acute Toxicity

Overdosage of neostigmine can induce a cholinergic crisis. Clinical signs can include: nausea, vomiting, diarrhea, excessive salivation and drooling, sweating (in animals with sweat glands), miosis, lacrimation, increased bronchial secretions, bradycardia or tachycardia, cardiospasm, bronchospasm, hypotension, muscle cramps and weakness, agitation, restlessness, or paralysis. In patients with myasthenia gravis, it may be difficult to distinguish between a cholinergic crisis and myasthenic crisis. A test dose of edrophonium should differentiate between the two.

Treat cholinergic crisis by temporarily ceasing neostigmine therapy and instituting treatment with atropine (doses are listed in the Atropine monograph). Maintain adequate respirations using mechanical assistance if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving neostigmine and may be of significance in veterinary patients:

- **ATROPINE:** Atropine will antagonize the muscarinic effects of neostigmine and some clinicians routinely use the two together, but concurrent use should be used cautiously as atropine can mask the early clinical signs of cholinergic crisis
- **CORTICOSTEROIDS:** May decrease the anticholinesterase activity of neostigmine; after stopping corticosteroid therapy, neostigmine may cause increased anticholinesterase activity
- **DEXPANTHENOL:** Theoretically, dexpantenol may have additive effects when used with neostigmine
- **MAGNESIUM:** Anticholinesterase therapy may be antagonized by administration of parenteral magnesium therapy, as it can have a direct depressant effect on skeletal muscle
- **MUSCLE RELAXANTS:** Neostigmine may prolong the Phase I block of depolarizing muscle relaxants (e.g., **succinylcholine**, **decamethonium**) and edrophonium antagonizes the actions of non-depolarizing neuromuscular blocking agents (e.g., **pancuronium**, **tubocurarine**, **gallamine**, **vecuronium**, **atracurium**, etc.)

Doses**■ DOGS:**

- For treatment of myasthenia gravis: 0.04 mg/kg IM q6h to bypass the problem of oral medication in actively regurgitating animals (Inzana 2000)
- For diagnosis of myasthenia gravis: 0.05 mg/kg IM (diagnostic for MA if clinical improvement occurs in 15–30 minutes; pre-treat with atropine) (LeCouteur 1988)
- For treatment of curare overdoses: 0.001 mg/kg SC, follow with IV injection of atropine (0.04 mg/kg) (Bailey 1986)

■ CATS:

For treatment of myasthenia gravis:

- 0.04 mg/kg IM q6h to bypass the problem of oral medication in actively regurgitating animals (Inzana 2000)

■ CATTLE:

- 1 mg/100 lbs of body weight SC; repeat as indicated (Package Insert; *Stiglyn® 1:500-P/M*—Mallinckrodt)

■ HORSES: (Note: ARCI UCGFS Class 3 Drug)

- 1 mg/100 lbs of body weight SC; repeat as indicated (Package Insert; *Stiglyn® 1:500-P/M*—Mallinckrodt)

For treatment of paralytic ileus of large colon:

- 2–4 mg SC q2h. Use after correction of large bowel displacement; discontinue when GI motility returns. May cause increased secretion into GI tract and, therefore, may be harmful in small intestinal disease. Does not produce progressive contractions of small intestine. (Stover 1987)
- 0.02 mg/kg SC; duration of action may be very short (15–30 minutes); does not increase propulsive motility of jejunum and may delay gastric emptying time. (Clark and Becht 1987)
- 0.44 mg/kg (approximately 2 mg total dose for a 450 kg horse) SC or IV; may be repeated every 1/2 to 2 hours. If ineffective and no adverse effects seen, may increase dose in 2 mg increments to a total of 10 mg per treatment. (Moore 1999)
- For ileus with marked colonic distension in foals secondary to *C. perfringens* type C: 1–2 mg (2 mg for foals greater than 250 lb) SC, 2–3 doses at 1–hour intervals then as needed. (Slovic 2003a)
- 0.025 mg/kg SC q2–6h (Hassel 2005)

■ SWINE:

- 2–3 mg/100 lbs of body weight IM; repeat as indicated (Package Insert; *Stiglyn® 1:500-P/M*—Mallinckrodt)
- 0.03 mg/kg (Davis 1986)

■ SHEEP:

- 1–1.5 mg/100 lbs of body weight SC; repeat as indicated (Package Insert; *Stiglyn® 1:500-P/M*—Mallinckrodt)
- 0.01–0.02 mg/kg (goats also) (Davis 1986)

Monitoring

Dependent on reason for use.

- Adverse reactions (see Adverse Effects and Overdosage above)
- Clinical efficacy

Client Information

- This product should only be used by professionals in locations where the drug's effects can be monitored.

Chemistry/Synonyms

Synthetic quaternary ammonium parasympathomimetic agents, neostigmine bromide and neostigmine methylsulfate both occur as odorless, bitter-tasting, white, crystalline powders that are very soluble in water and soluble in alcohol. The melting point of neostigmine methylsulfate is from 144–149°. The pH of the commercially available neostigmine methylsulfate injection is from 5–6.5.

Neostigmine methylsulfate may also be known as: neostigmine metilsulfate, neostigmine methylsulphate, neostigmini metilsulfas, proserinum, *Glycostigmin®*, *Intrastigmina®*, *Neostig-Reu®*, *Normastigmin®*, *Prostigmin®*, *Prostigmina®*, *Prostigmine®*, *Stiglyn®*, or *Tilstigmin®*.

Storage/Stability/Compatibility

Neostigmine bromide tablets should be stored at room temperature in tight containers. Neostigmine methylsulfate injection should be stored at room temperature and protected from light; avoid freezing.

Neostigmine methylsulfate injection is reportedly physically **compatible** with the commonly used IV replacement solutions and the following drugs: glycopyrrolate, pentobarbital sodium, and thiopental sodium.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Neostigmine Methylsulfate Injection: 1:1000 (1 mg/mL), 1:2000 (0.5 mg/mL), 1:4000 (0.25 mg/mL) in 1 mL amps (only 1:2000 and 1:4000) and 10 mL vials; *Prostigmin®* (ICN); generic; (Rx)

NIACINAMIDE (NICOTINAMIDE)

(nye-a-sin-a-mide)

IMMUNOMODULATOR; NUTRITIONAL

Prescriber Highlights

- Used in canine medicine in combination with tetracycline for treatment of discoid lupus erythematosus; may be useful in other immune-mediated dermatologic conditions such as sterile pyogranulomas, idiopathic onychodystrophy, pemphigus foliaceus, & pemphigus erythematosus
- Possible Contraindications: Liver disease, active peptic ulcers, or hypersensitivity to it
- Adverse Effects: Anorexia, vomiting, & lethargy; occasionally increases in liver enzymes seen
- Improvement may be gradual & take 6–8 weeks
- Inexpensive

Uses/Indications

When used in conjunction with tetracycline, niacinamide may be useful for the treatment of discoid lupus erythematosus in dogs. It is occasionally been found to be useful in sterile pyogranulomas, idiopathic onychodystrophy, pemphigus foliaceus and pemphigus erythematosus. It may take 1–2 months before efficacy is noted.

Pharmacology/Actions

While niacinamide is an essential nutrient in humans (necessary for lipid metabolism, tissue respiration, and glycogenolysis) its primary pharmacologic use (in combination with tetracycline for discoid lupus erythematosus) in dogs is secondary to its action of blocking IgE-induced histamine release and degranulation of mast cells. When used with tetracycline, niacinamide may suppress leukocyte chemotaxis secondary to complement activation by antibody-antigen complexes. It also inhibits phosphodiesterases and decreases the release of proteases. In combination with tetracycline's immunomodulating and antiinflammatory effects, efficacy has been noted in up to two-thirds of dogs treated for DLE. While niacinamide and niacin act identically as vitamins, niacinamide does not affect blood lipid levels or the cardiovascular system.

Pharmacokinetics

Niacinamide is absorbed well after oral administration and widely distributed to body tissues. Niacinamide is metabolized in the liver to several metabolites that are excreted into the urine. At physiologic doses, only a small amount of niacinamide is excreted into the urine unchanged, but as dosages increase, larger quantities are excreted unchanged.

Contraindications/Precautions/Warnings

In humans, niacinamide therapy is contraindicated in patients with liver disease, active peptic ulcers, or hypersensitivity to the drug.

Adverse Effects

Adverse effects of niacinamide in dogs are uncommon, but may include anorexia, vomiting, and lethargy. Occasionally, increases in liver enzymes may be noted.

Reproductive/Nursing Safety

While niacinamide alone should be safe to use in pregnant and lactating animals, its use in combination with tetracycline may not be safe.

Overdosage/Acute Toxicity

There is unlikely to be a problem with niacinamide overdoses other than acute GI distress.

Drug Interactions

Niacinamide and tetracycline treatment does not interfere with antibody production associated with routine vaccinations in dogs. Also see the tetracycline monograph for additional drug interactions if using combination therapy.

The following drug interactions have either been reported or are theoretical in humans or animals receiving niacinamide and may be of significance in veterinary patients:

- **INSULIN/ORAL ANTIDIABETIC AGENTS:** In diabetic humans, dosage adjustments for insulin or oral antidiabetic agents have sometimes been necessary after initiating niacinamide therapy.

Doses

■ DOGS:

For discoid lupus erythematosus:

- a) For dogs weighing 10 kg or more: 500 mg of niacinamide and 500 mg of tetracycline PO q8h. For dogs weighing from 5–10 kg: 250 mg of each drug PO q8h. For dogs weighing less than 5 kg: 100 mg of each drug PO q8h. Improvement is usually noted within 6 weeks. (White 2000)
- b) Dogs weighing more than 10 kg: 500 mg of niacinamide and 500 mg of tetracycline PO q8h. For dogs weighing less than 10 kg: 250 mg of each PO q8h. May use in combination with corticosteroids and Vitamin E. If adverse effects become a

problem, reduce dose of niacinamide first. May also try this regimen for pemphigus foliaceus or pemphigus erythematosus (approximately (Campbell 1999)

For various immune-mediated diseases (discoid lupus erythematosus, pemphigus erythematosus, pemphigus foliaceus, vasculitis, sterile pyelogramuloma, dermatomyositis, and lupoid onychodystrophy:

- a) For dogs less than 10 kg: 250 mg each of niacinamide and tetracycline PO three times daily.

For dogs larger than 10 kg: 500 mg each of niacinamide and tetracycline PO three times daily. May substitute doxycycline for tetracycline at 5 mg/kg PO once a day. (Tapp 2002)

Monitoring

- Efficacy
- Adverse effects (baseline and occasional monitoring of liver enzymes is suggested)

Client Information

- Give as directed. Improvement may not be noted for 6–8 weeks.
- If dog's condition deteriorates or if adverse effects are a problem, contact veterinarian.

Chemistry/Synonyms

Niacinamide, also commonly known as nicotinamide, occurs as a white crystalline powder. It is odorless or nearly odorless and has a bitter taste. It is freely soluble in water or alcohol.

Niacinamide may also be known as: nicotinamide, nicotinamidum, nicotinic acid amide, nicotylamide, Vitamin B(3), or Vitamin PP.

Storage/Stability/Compatibility

Store niacinamide tablets in tight containers at room temperature unless otherwise labeled. Niacinamide is **incompatible** with alkalis or strong acids.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Niacinamide (Nicotinamide) Tablets: 100 mg & 500 mg; generic; (OTC); also available in bulk powder.

NITAZOXANIDE

(nye-tah-zox-ah-nide) Navigator®

ANTIPARASITIC AGENT

Prescriber Highlights

- Drug that has activity against a variety of protozoa, nematodes, bacteria, & trematodes, including *Sarcocystis neurona*, giardia, cryptosporidia, & *Helicobacter pylori*
- Approved for use in horses (EPM) & humans (Giardia & Cryptosporidia)
- Interest in using in other companion animals (e.g., dogs, cats), but data is lacking to support use
- Adverse effects in horses may be therapy limiting; very well tolerated in humans

Uses/Indications

Nitazoxanide oral paste is indicated for the treatment of horses with equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*.

In humans, nitazoxanide is approved (in the USA) for use in treating diarrhea caused by *Cryptosporidium parvum* and *Giardia lamblia* in pediatric patients from ages 1 to 11 years old.

Because of the drug's spectrum of activity and apparent safety, there is considerable interest in using it in a variety of companion animal species, but data is lacking for specific indications and dosages.

Pharmacology

While the precise mechanism of action of nitazoxanide is unknown, its active metabolites tizoxanide and tizoxanide glucuronide, are thought to inhibit the pyruvate:ferredoxin oxidoreductase (PFOR) enzyme-dependent electron transfer reactions essential to anaerobic energy metabolism. Nitazoxanide has activity against a variety of protozoa, nematodes, bacteria, and trematodes, including *Sarcocystis neurona*, giardia, cryptosporidia, and *Helicobacter pylori*.

Pharmacokinetics

Following oral administration in horses, nitazoxanide is absorbed and rapidly converted to tizoxanide (desacetyl-nitazoxanide). Peak levels of tizoxanide are attained between 2–3 hours and are not detectable by 24 hours post dosing.

In humans, nitazoxanide is not detectable in plasma, but peak levels of tizoxanide and tizoxanide glucuronide occur about 3–4 hours post dose. More than 99% of tizoxanide is bound to plasma proteins. Tizoxanide is excreted in the urine, bile, and feces; the glucuronide metabolite is secreted in the urine and bile.

Contraindications/Precautions/Warnings

In horses, the drug is labeled as contraindicated in horses less than one year of age and those that are sick or debilitated for reasons other than EPM. The drug should be used with caution in stallions and other horses predisposed to developing laminitis. Safety for use in animals with compromised renal or hepatic function has not been established; use with caution. The manufacturer has not evaluated nitazoxanide in horses weighing more than 545 kg (1200 lbs).

Adverse Effects

In horses, the following adverse effects are most commonly reported: fever, reduced appetite/anorexia, and lethargy/depression. Other adverse effects include decreased gut sounds, scant feces, loose/malodorous or discolored feces/diarrhea, colic, laminitis, increased water consumption, discolored urine, head and/or limb edema, or weight loss. The manufacturer states that stallions may be more prone to developing laminitis than either geldings or mares.

Nitazoxanide may disrupt normal flora in the horse leading to enterocolitis. If patient develops any of the following: a high fever ($>103^{\circ}\text{F}$), scant or loose feces, diarrhea, colic, or signs of laminitis, nitazoxanide treatments should be stopped immediately and appropriate veterinary care be initiated.

A so-called "treatment crisis" may develop, particularly early in therapy (first two weeks) and is thought to be caused by CNS inflammation secondary to dead or dying protozoa. Common signs include neurological deficits, fever, lethargy, and decreasing appetite. Treatment with antiinflammatory agents may be indicated. Treatment may continue if horse is closely monitored for other adverse reactions (e.g., anorexia, diarrhea, colic, laminitis).

In humans, nitazoxanide appears to be well tolerated and adverse effect rates are similar to placebo. Rarely, sclera may turn yellow secondary to drug disposition, but return to normal after drug discontinuation.

Reproductive/Nursing Safety

The reproductive safety of nitazoxanide has not been determined in breeding stallions or in breeding or lactating mares. In pregnant humans, nitazoxanide is designated by the FDA as a category **B** drug (*Animal studies have not demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*) Nitazoxanide did not affect male or female fertility in rats given approximately 66 times the human dose. It did not cause fetal harm in pregnant rats or rabbits given 48 times and 3 times the human dose, respectively.

It is unknown if tizoxanide is excreted into milk.

Overdosage/Acute Toxicity

There is limited information available on the acute toxicity of nitazoxanide. The oral LD₅₀ for cats and dogs is greater than 10 g/kg. Repeated doses of 450 mg/kg in rats caused intense salivation and increased liver and spleen weights. In horses given approximately 5 times the labeled dose, all developed anorexia, diarrhea, and lethargy, and testing was halted after 4 days of study. Human volunteers have taken doses of up to 4 grams without significant adverse effects occurring. In the event of an overdose, it is suggested to observe the patient closely and treat adverse effects in a supportive manner.

Drug Interactions

No specific drug interactions have been noted to date, but the veterinary and human manufacturers warn to use with caution if the patient is receiving other drugs that are highly protein bound and with a narrow therapeutic index.

Laboratory Considerations

No specific laboratory interactions or considerations noted.

Doses

■ HORSES:

For equine protozoal myeloencephalitis (EPM) caused by *Sarcocystis neurona*:

- a) For a 28 day course of therapy: Days 1–5: 25 mg/kg (11.36 mg/lb) PO once daily; Days 6–28: 50 mg/kg (22.72 mg/lb) PO once daily. See directions for use in client information section that follows. (Package insert; *Navigator*®—Idexx)

Monitoring

- Clinical efficacy
- Weekly body weight
- Adverse reactions; if adverse reactions occur, the manufacturer recommends performing a physical exam, CBC, serum albumin, total serum protein and body weight.

Client Information

- Always provide the Client Information Sheet (found on the inside of the upper flap and inside the box of syringes) to the animal owner or person treating the horse with each prescription. Clients must understand and accept the potential associated risks versus benefits of therapy.

DIRECTIONS FOR USE (from package insert):

- Step 1: Obtain an accurate body weight periodically (once a week) to ensure the correct dose is administered. Use a scale or the weight tape provided in the NAVIGATOR dispensing box.
- Step 2: Open the foil pouch and remove the NAVIGATOR syringe. Set the dosage ring for the appropriate dose according to the following schedule. To set the dosage ring on the syringe plunger, rotate (dial) the top of the ring to the appropriate dosing mark.
 - Day 1—Use the syringe in the space marked #1 and set the dosage ring to one-half (1/2) the horse's weight in pounds.
 - Day 2—Use the partially used syringe from Day 1 and set the dosage ring to the full weight of the horse in pounds (this will deliver the same amount as administered on Day 1).
 - Day 3—Use the syringe in the space marked #2 and set the dosage ring to one-half (1/2) the horse's weight in pounds.
 - Day 4—Use the partially used syringe from Day 3 and set the dosage ring to the full weight of the horse in pounds (this will deliver the same amount as administered on Day 3).
 - Day 5—Use the syringe in the space marked #3 and set the dosage ring to one-half (1/2) the horse's weight in pounds. Syringe #3 will be only partially used. Save this syringe until dosing is complete and then discard it along with the other syringes.
 - Days 6–28—Use the remaining syringes and set the dosage ring to the full weight of the horse in pounds.
- Step 3: Ensure the horse's mouth contains no feed. Remove the cover from the tip of the syringe and insert the tip into the horse's mouth at the interdental space. Depress the plunger until it is stopped by the dosage ring. The dose should be deposited on the back of the tongue or deep into the cheek pouch.
- Step 4: To aid swallowing of paste, immediately raise the horse's head for a few seconds after dosing.
- Step 5: Clean the tip of the syringe with a clean disposable towel and replace the cover on the tip of the syringe. Return the syringe to the original space in the NAVIGATOR dispensing box.
- Step 6: Repeat until the horse has been treated for 28 days. Weigh the horse weekly and set the dose based upon the current body weight to ensure accurate dosing.
- Step 7: At the end of the treatment period, all empty and partially empty syringes should be discarded. Do not reuse dosing syringes.
- When used in horses, the manufacturer states to monitor for adverse reactions at least once daily for the duration of treatment.
- Contact the veterinarian immediately if any of the following adverse effects occur: fever, reduced appetite/anorexia, lethargy/depression, decreased gut sounds, scant feces, loose/malodorous or discolored feces/diarrhea, colic, laminitis, increased water consumption, discolored urine, head and/or limb edema, or weight loss.

Chemistry/Synonyms

A nitrothiazolyl-salicylamide derivative antiparasitic agent, nitazoxanide occurs as a light yellow powder. It is slightly soluble in ethanol and practically insoluble in water.

Nitazoxanide may also be known as: PH-5776, *Alinia*®, *Daxon*®, *Heliton*®, and *Navigator*®.

Storage/Stability

The equine-approved oral paste should be stored below 30°C (86°F); do not freeze. The human-approved powder for oral suspension should be stored at 25°C (77°F); excursions permitted to 15–30°C (59–86°F). Once suspended with tap water, the oral sus-

pension should be kept in tightly closed containers at room temperature and discarded after 7 days.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Nitazoxanide oral paste (32%, 320 mg/gram of paste) oral dose syringes; in boxes of 26 syringes. Each syringe contains 85 grams of paste. Each syringe will treat a horse weighing up to 1200 lbs and one box of syringes will treat a 1200 lb horse for 28 days. *Navigator*® (Idexx); (Rx). Approved for horses not to be used for human consumption.

HUMAN-LABELED PRODUCTS:

Nitazoxanide Tablets: 500 mg; *Alinia*® (Romark Laboratories); (Rx)

Nitazoxanide Powder for Oral Suspension: 20 mg/mL (100 mg/5 mL after reconstitution) in 60 mL; *Alinia*® (Romark Laboratories); (Rx)

NITENPYRAM

(nye-ten-pye-rum) Capstar®, Program®

ORAL INSECTICIDE**Prescriber Highlights**

- Oral insecticide used primarily as a flea adulticide in dogs & cats; may also have efficacy for other conditions (e.g., maggots)
- Very safe
- Not effective alone for flea eggs or other immature forms
- Over-the-counter

Uses/Indications

Nitenpyram is indicated as a flea adulticide in dogs and cats. It does not kill ticks, flea eggs, larvae or immature fleas. Nitenpyram may be effective for treating fly larvae (maggots) of various species.

Pharmacology/Actions

Nitenpyram enters the systemic circulation of the adult flea after consuming blood from a treated animal. It binds to nicotinic acetylcholine receptors in the postsynaptic membranes and blocks acetylcholine-mediated neuronal transmission causing paralysis and death of the flea. It does not inhibit acetylcholinesterase. Efficacy appears to be greater than 95% (kill rate) in dogs or cats within 6 hours of treatment. When combined with an insect growth regulator (e.g., lufenuron), immature stages of fleas may also be controlled.

Pharmacokinetics

Nitenpyram is rapidly and practically completely absorbed after oral administration. Peak levels occur about 80 minutes after dosing in dogs; about 40 minutes in cats. Elimination half-lives are about 3 hours for dogs; 8 hours for cats. Nitenpyram is excreted primarily unchanged in the urine. In dogs, about 3% of a dose is excreted in the feces; in cats about 5% is excreted in the feces.

Contraindications/Precautions/Warnings

Nitenpyram is not labeled to be used in animals under 2 pounds of body weight or under 4 weeks of age.

Adverse Effects

Nitenpyram is tolerated well. As fleas begin to die, animal may begin scratching. This effect is temporary and due to the fleas and not the medication.

Reproductive/Nursing Safety

Nitenpyram is probably safe to use in breeding, pregnant, or lactating animals.

Overdosage/Acute Toxicity

Nitenpyram is relatively safe in high dosages to mammals. The oral LD₅₀ in rats is approximately 1.6 grams/kg. Cats or dogs given 10 times the usual dose for 14 days showed no untoward effects. In the circumstance of a massive overdose, contact an animal poison control center for additional guidance.

Drug Interactions

No specific drug interactions were located. Nitenpyram has reportedly been used safely with a variety of other medications and other flea products.

Laboratory Considerations

No specific laboratory interactions or considerations noted.

Doses**■ DOGS:**

As a flea adulticide:

- a) For dogs weighing 2–25 lb. (0.9–11.36 kg): Give one 11.4 mg tablet PO. May be given as often as once per day. For dogs weighing 25–125 lb. (11.36–56.8 kg): Give one 57 mg tablet PO. May be given as often as once per day. May be given with or without food. (Label directions; *Capstar*®—Novartis)

■ CATS:

As a flea adulticide:

- a) For cats weighing 2–25 lb. (0.9–11.36 kg): Give one 11.4 mg tablet PO. May be given as often as once per day. May be given with or without food. (Label directions; *Capstar*®—Novartis)

■ REPTILES:

- a) For maggots: crush one 11.4 mg tablet into powder and give PO, as an enema, or on wound one time. (Klaphake 2005a)

Monitoring

- Efficacy

Client Information

- All animals in household should be treated.
- Because nitenpyram does not kill immature fleas, eggs, etc., it is usually used in combination with other products that will control those forms of fleas.
- Keep tablets out of reach of children.

Chemistry/Synonyms

A neonicotinoid insecticide, nitenpyram occurs as a pale yellow crystalline powder and is very soluble in water (840 mg/mL)

Nitenpyram may also be known as: TI-304, (E)-Nitenpyram, *Bestguard*®, and *Capstar*®.

Storage/Stability/Compatibility

Commercially available nitenpyram tablets should be stored at room temperature (15–30°C; 59–86°F). Shelf life is reported to be 3 years if stored below 25°C (76°F).

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Nitenpyram Oral Tablets: 11.4 mg and 57 mg in boxes containing blister packs of 6 tablets; *Capstar*® (Novartis); (OTC); Approved for use in dogs and cats.

Also available in combination packs with Lufenuron [*Program*® *Flavor Tabs* and *Capstar*® *Flea Management System for Dogs* and *Program*® *Flavor Tabs* (OTC); and *Capstar*® *Flea Management System for Cats* (OTC)] and in combination with milbemycin and lufenuron [*Sentinel*® *Flavor Tabs* and *Capstar*® *Flea Management System for Dogs* (Rx)].

HUMAN-LABELED PRODUCTS: None

NITROFURANTOIN

(nye-troe-fyoor-an-toyn) Macrochantin®, Macrobid®

URINARY ANTIMICROBIAL**Prescriber Highlights**

- Antibacterial used for susceptible UTI's
- Contraindications: Renal impairment; hypersensitivity to it
- Adverse Effects: Gastrointestinal disturbances & hepatopathy of most concern; may cause infertility in males or peripheral neuropathy
- Potentially teratogenic, may be toxic to neonates

Uses/Indications

Considered a urinary tract antiseptic, nitrofurantoin is used primarily in small animals, but also occasionally in horses in the treatment of lower urinary tract infections caused by susceptible bacteria. It is not effective in treating renal cortical or perinephric abscesses or other systemic infections.

Pharmacology/Actions

Nitrofurantoin usually acts as a bacteriostatic antimicrobial, but it may be bactericidal depending on the concentration of the drug and the susceptibility of the organism. The exact mechanism of action of nitrofurantoin has not been fully elucidated, but the drug apparently inhibits various bacterial enzyme systems, including acetyl coenzyme A. Nitrofurantoin has greater antibacterial activity in acidic environments.

Nitrofurantoin has activity against several gram-negative and some gram-positive organisms, including many strains of *E. coli*, *Klebsiella*, *Enterobacter*, *Enterococci*, *Staphylococcus aureus* and *epidermidis*, *Enterobacter*, *Citrobacter*, *Salmonella*, *Shigella*, and *Corynebacterium*. It has little or no activity against most strains of *Proteus*, *Serratia*, or *Acinetobacter* and has no activity against *Pseudomonas* spp.

Pharmacokinetics

Nitrofurantoin is rapidly absorbed from the GI tract and the presence of food may enhance the absorption of the drug. Macrocrystalline forms of the drug may be absorbed more slowly with less GI upset. Because of its slower absorption, urine levels of the drug may be prolonged.

Therapeutic levels in the systemic circulation are not maintained due to the rapid elimination of the drug after absorption. Approximately 20–60% of the drug is bound to serum proteins.

Peak urine levels occur within 30 minutes of dosing. The drug crosses the placenta and only minimal quantities of the drug are found in milk.

Approximately 40–50% of the drug is eliminated into urine unchanged via both glomerular filtration and tubular secretion. Some of the drug is metabolized, primarily in the liver. Elimination half-lives in humans with normal renal function average 20 minutes.

Contraindications/Precautions/Warnings

Nitrofurantoin is contraindicated in patients with renal impairment as the drug is much less efficacious and the development of toxicity is much more likely. The drug is also contraindicated in patients hypersensitive to it.

Adverse Effects

In dogs and cats, gastrointestinal disturbances (primarily vomiting) and hepatopathy can occur with this drug. Rarely, reversible myasthenic-like effects have been seen in dogs. Neuropathies, chronic active hepatitis, hemolytic anemia, and pneumonitis have been described in humans, but are believed to occur very rarely in animals.

Reproductive/Nursing Safety

In humans, the drug is contraindicated in pregnant patients at term and neonates as hemolytic anemia can occur secondary to immature enzyme systems. Safe use of the drug during earlier stages of pregnancy has not been determined. Nitrofurantoin has been implicated in causing infertility in male dogs. Use only when the benefits of therapy outweigh the potential risks.

Nitrofurantoin is excreted into maternal milk in very low concentrations. Safety for use in the nursing mother or offspring has not been established.

Overdosage/Acute Toxicity

No specific information was located. Because the drug is rapidly absorbed and excreted, patients with normal renal function should require little therapy when mild overdoses occur. If the ingestion was relatively recent, massive overdoses should be handled by emptying the gut using standard protocols; patient should then be monitored for adverse effects (see above).

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nitrofurantoin and may be of significance in veterinary patients:

- **FLUOROQUINOLONES** (e.g., **enrofloxacin**, **ciprofloxacin**): Nitrofurantoin may antagonize the antimicrobial activity of the fluoroquinolones and concomitant use is best avoided
- **FOOD** or **ANTICHOLINERGIC DRUGS** may increase the oral bioavailability of nitrofurantoin
- **MAGNESIUM TRISILICATE CONTAINING ANTACIDS**: May inhibit the oral absorption of nitrofurantoin
- **PROBENECID**: May inhibit the renal excretion of nitrofurantoin potentially increasing its toxicity and reducing its effectiveness in urinary tract infections

Laboratory Considerations

- Nitrofurantoin may cause false-positive **urine glucose** determinations if using cupric-sulfate solutions (Benedict's reagent, *Clinitest*®). Tests using glucose oxidase methods (*Tes-Tape*®, *Clinistix*®) are not affected by nitrofurantoin.
- Nitrofurantoin may cause decreases in **blood glucose**, and increases in **serum creatinine**, **bilirubin** and **alkaline phosphatase**.

Doses

■ DOGS:

For susceptible bacterial urinary tract infections:

- a) 4 mg/kg PO q6h (Osborne and Lulich 1987)
- b) For recurrent UTI: Conventional dose: 4 mg/kg, PO q8h; Prophylactic dose: 3–4 mg/kg, PO q24h (should be given at night after micturition and immediately before bedtime) (Polzin and Osborne 1985)
- c) 4 mg/kg PO q6–8h (Brovida 2003)
- d) 5 mg/kg PO q8h (Dowling 2007)
- e) 4.4 mg/kg PO three times daily (Senior 2005)

■ CATS:

For susceptible bacterial urinary tract infections:

- a) 4 mg/kg, PO q6h (Osborne and Lulich 1987)
- b) For recurrent UTI: Conventional dose: 4 mg/kg, PO q8h; Prophylactic dose: 3–4 mg/kg, PO q24h (should be given at night after micturition and immediately before bedtime) (Polzin and Osborne 1985)
- c) 4 mg/kg PO q6–8h (Brovida 2003)

■ HORSES:

For susceptible urinary tract infections:

- a) 2.5–4.5 mg/kg, PO three times daily (Robinson 1987)
- b) 10 mg/kg, PO daily (Huber 1988a)

Monitoring

- Clinical efficacy
- Adverse effects
- Periodic liver function tests should be considered with chronic therapy

Chemistry/Synonyms

A synthetic, nitrofurantoin antibacterial, nitrofurantoin occurs as a bitter tasting, lemon-yellow, crystalline powder with a pK_a of 7.2. It is very slightly soluble in water or alcohol.

Nitrofurantoin may also be known as: furadonin or nitrofurantoinum, *Furadantin*®, *Macrobid*®, and *Macrochantin*®.

Storage/Stability/Compatibility

Nitrofurantoin preparations should be stored in tight containers at room temperature and protected from light. The oral suspension should not be frozen. Nitrofurantoin will decompose if it comes into contact with metals other than aluminum or stainless steel.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Nitrofurantoin Macrocrystals Capsules: 25 mg, 50 mg, 100 mg (as macrocrystals) and 100 mg (as monohydrate/macrocrystals); *Macrochantin*® and *Macrobid*® (Procter and Gamble Pharm); generic; (Rx)

Nitrofurantoin Oral Suspension: 5 mg/mL (25 mg/5 mL) in 60 mL and 470 mL; *Furadantin*® (First Horizon); (Rx)

NITROGLYCERIN, TOPICAL(nye-troe-*gli*-ser-in) NTG, Nitro-bid®, Minitran®**VENODILATOR****Prescriber Highlights**

- ▶ Topical, oral, & injectable venodilator; usually used topically in veterinary medicine for CHF or hypertension
- ▶ Contraindications: anemia or hypersensitivity to nitrates. Caution: cerebral hemorrhage or head trauma, diuretic-induced hypovolemia, or other hypotensive conditions.
- ▶ Adverse Effects: rashes at the application sites & orthostatic hypotension; transient headaches common in humans & may be a problem for some animals
- ▶ Rotate application sites
- ▶ Wear gloves when applying; avoid human skin contact

Uses/Indications

Topical nitroglycerin in small animal medicine is used primarily as an adjunctive vasodilator in heart failure and cardiogenic edema. It is also used as an anti-anginal agent, antihypertensive (acute), and topically to treat Raynaud's disease in humans.

Pharmacology/Actions

Nitroglycerin relaxes vascular smooth muscle primarily on the venous side, but a dose related effect on arterioles is possible. Preload (left end-diastolic pressure) is reduced from the peripheral pooling of blood and decreased venous return to the heart. Because of its arteriolar effects, depending on the dose, afterload may also be reduced. Myocardial oxygen demand and workload are reduced and coronary circulation can be improved.

Pharmacokinetics

Nitroglycerin topical ointment is absorbed through the skin, with an onset of action usually within 1 hour and duration of action of 2–12 hours. It is generally dosed in dogs and cats q6–8 hours (three to four times a day). The transdermal patches have a wide inter-patient bioavailability. Nitroglycerin has a very short half-life (1–4 minutes in humans) and is metabolized in the liver. At least two metabolites have some vasodilator activity and have longer half-lives than NTG.

Contraindications/Precautions/Warnings

Nitrates are contraindicated in patients with severe anemia or those hypersensitive to them. They should be used with caution (if at all) in patients with cerebral hemorrhage or head trauma, diuretic-induced hypovolemia or other hypotensive conditions.

Adverse Effects

Most common side effects seen are rashes at the application sites and orthostatic hypotension. If hypotension is a problem, reduce dosage. Transient headaches are a common side effect seen in humans and may be a problem for some animals.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **C** (*These*

drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.)

It is not known whether nitrates are excreted in maternal milk; use with caution in nursing animals.

Overdosage/Acute Toxicity

If severe hypotension results after topical administration, wash the site of application to prevent any more absorption of ointment. Fluids may be administered if necessary. Epinephrine is contraindicated as it is ineffective and may complicate the animal's condition.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nitroglycerin and may be of significance in veterinary patients:

- **ANTIHYPERTENSIVE DRUGS, OTHER:** Use of nitroglycerin with other antihypertensive drugs may cause additive hypotensive effects
- **PHENOTHIAZINES:** May increase hypotensive effects
- **SILDENAFIL** (and other **PDE INHIBITORS**): May profoundly increase risk for hypotension

Doses

Note: For the treatment of heart failure, nitroglycerin is not generally used alone.

■ **DOGS:**

For adjunctive treatment of heart failure:

- a) 1/2 inch per 2.27 kg (5 lbs) of body weight applied to a hairless area (*e.g.*, inside the earflap) every 12 hours. Person applying should use gloves and avoid contact with the product. (Kittleson 2000)
- b) If nitroprusside not used, 2% NTG at 1/4 to 1 inch q6–12h; apply to hairless area in the axilla or groin. (Macintire 2006a)
- c) Using the 2.5–10 mg/24hr transdermal patch: 12 hours on, 12 hours off (Fox 2003a)
- d) 1/4–2 inches applied directly to the patient's tongue every 8 hours during the first 48 hours. All animals tolerate the ointment given orally. (Lichtenberger 2006b)
- e) For any patient with cardiogenic pulmonary edema that is headed for oxygen: 1/4 inch for small dogs up to 1 inch for large dogs on the inner ear pinnae, groin or axilla as needed q8h for the first 24 hours. Wear gloves to apply. (DeFrancesco 2006)

■ **CATS:**

For adjunctive treatment of heart failure:

- a) 1/8th to 1/4 inch applied to a hairless area (*e.g.*, inside the earflap) every 4–6 hours. Person applying should use gloves and avoid contact with the product. (Kittleson 2000)
- b) To enhance resolution of pulmonary edema: 1/4 to 1/2 inch topically q6h; to reduce nitrate tolerance, alternate 12 hrs with and 12 hrs without nitroglycerin therapy. (Fox 2007b)
- c) Using the 2.5–5 mg/24hr transdermal patch: 12 hours on, 12 hours off (Fox 2003a)
- d) 1/4 inch applied directly to the patient's tongue every 8 hours during the first 48 hours. All animals tolerate the ointment given orally. (Lichtenberger 2006b)
- e) For any patient with cardiogenic pulmonary edema that is headed for oxygen: 1/4 inch on the inner ear pinnae, groin or axilla as needed q8h for the first 24 hours. Wear gloves to apply. (DeFrancesco 2006)

For adjunctive treatment of hypertension:

- a) 1/4 inch applied to pinna q6–8h (Norsworthy 2007)

■ FERRETS:

For adjunctive therapy for heart failure:

- a) 1/8th inch strip applied to inside of pinna q12h for the first 24 hours of therapy (Hoeffer 2000)
- b) For dilative cardiomyopathy: 1/8th of an inch applied to shaved skin once to twice daily. Apply to ear pinna or skin of thigh. May cause hypotension. (Williams 2000)

Monitoring

- Clinical efficacy
- Sites of application for signs of rash
- Blood pressure, particularly if hypotensive effects are seen

Client Information

- Dosage is measured in inches of ointment; use papers supplied with product to measure appropriate dose. Wear gloves (non-permeable) when applying.
- Do not pet animal where ointment has been applied
- Rotate application sites. Recommended application sites include: groin, inside the ears, and thorax. Rub ointment into skin well. If rash develops, do not use that site again until cleared.
- Contact veterinarian if rash persists or animal's condition deteriorates
- There is no danger of explosion or fire with the use of this product

Chemistry/Synonyms

Famous as an explosive, nitroglycerin (NTG) occurs undiluted as a thick, volatile, white-pale yellow flammable, explosive liquid with a sweet, burning taste. The undiluted drug is soluble in alcohol and slightly soluble in water. Because of obvious safety reasons, nitroglycerin is diluted with lactose, dextrose, propylene glycol, alcohol, etc. when used for pharmaceutical purposes.

Nitroglycerin may also be known as: glyceryl trinitrate, glonoine, GTN; nitroglycerol, NTG, trinitrin, or trinitroglycerin, *Minitran*®, *Nitro-bid*®, *Nitrek*® and *Nitro-Dur*®.

Storage/Stability

The topical ointment should be stored at room temperature and the cap firmly attached. For storage/stability and compatibility for dosage forms other than the topical ointment, see specialized references or the package inserts for each product.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 3 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Note: Many dosage forms of nitroglycerin are available for human use, including sublingual tablets, buccal tablets, lingual spray, extended-release oral capsules and tablets, and parenteral solutions for IV infusion. Because the use of nitroglycerin in small animal medicine is practically limited to the use of topical ointment or transdermal patches, those other dosage forms are not listed here.

Nitroglycerin Topical Ointment: 2% in a lanolin-white petrolatum base in 30 g and 60 g tubes and UD 1 g; *Nitro-bid*® (Fougera); generic; (Rx)

Nitroglycerin Transdermal Systems (patches): 0.1 mg/hr 0.2 mg/hr, 0.3 mg/hr, 0.4 mg/hr, 0.6 mg/hr & 0.8 mg/hr; *Minitran*® (3M); *Nitro-Dur*® (Key); *Nitrek*® (Bertek); generic; (Rx) **Note:** Various products contain differing quantities of nitroglycerin and patch surface area size, but release rates of drug are identical for a given mg/hr.

NITROPRUSSIDE SODIUM

(nye-troe-pruss-ide) Nitropress®, Sodium Nitroprusside
VASODILATOR

Prescriber Highlights

- Vascular, smooth muscle relaxant used for acute/severe hypertension; acute heart failure secondary to mitral regurgitation & in combination with dopamine for refractory CHF
- Contraindications: Compensatory hypertension, inadequate cerebral circulation, or during emergency surgery in patients near death. Caution: Geriatric patients, hepatic insufficiency, severe renal impairment, hyponatremia, or hypothyroidism.
- Adverse effects: Hypotensive effects; potentially: nausea, retching, restlessness, apprehension, muscle twitching, dizziness
- May be irritating at the infusion site; avoid extravasation.
- Continued use may lead to potential thiocyanate & cyanide toxicity
- Use only in an ICU setting; monitoring essential

Uses/Indications

In human medicine, nitroprusside is indicated for the management of hypertensive crises, acute heart failure secondary to mitral regurgitation, and severe refractory CHF (often in combination with dopamine). Its use in veterinary medicine is generally reserved for the treatment of critically ill patients with those conditions only when constant blood pressure monitoring can be performed.

Pharmacology/Actions

Nitroprusside is an immediate acting intravenous hypotensive agent that directly causes peripheral vasodilation (arterial and venous) independent of autonomic innervation. It produces a lowering of blood pressure, an increase in heart rate, a mild decrease in cardiac output, and a significant reduction in total peripheral resistance. Unlike the organic nitrates, tolerance does not develop to nitroprusside.

Pharmacokinetics

After starting an IV infusion of nitroprusside, reduction in blood pressure and other pharmacologic effects begin almost immediately. Blood pressure will return to pretreatment levels within 1–10 minutes following cessation of therapy.

Nitroprusside is metabolized non-enzymatically in the blood and tissues to cyanogen (cyanide radical). Cyanogen is converted in the liver to thiocyanate where it is eliminated in the urine, feces, and exhaled air. The half-life of cyanogen is 2.7–7 days if renal function is normal, but prolonged in patients with impaired renal function or with hyponatremia.

Contraindications/Precautions/Warnings

Nitroprusside is contraindicated in patients with compensatory hypertension (e.g., AV shunts or coarctation of the aorta; Cushing's reflex), inadequate cerebral circulation, or during emergency surgery in patients near death.

Nitroprusside must be used with caution in patients with hepatic insufficiency, severe renal impairment, hyponatremia, or hypothyroidism. When nitroprusside is used for controlled hypotension during surgery, patients may have less tolerance to hypovolemia, anemia, or blood loss. Geriatric patients may be more sensitive to the hypotensive effects of nitroprusside.

Adverse Effects

Most adverse reactions from nitroprusside are associated with its hypotensive effects, particularly if blood pressure is reduced too rapidly. Clinical signs such as nausea, retching, restlessness, apprehension, muscle twitching, and dizziness have been reported in humans. These effects disappear when the infusion rate is reduced or stopped. Nitroprusside may be irritating at the infusion site; avoid extravasation.

Continued use may lead to potential thiocyanate and cyanide toxicity (see Overdosage section).

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: *C* (*These drugs may have potential risks. Studies in people or laboratory animals have uncovered risks, and these drugs should be used cautiously as a last resort when the benefit of therapy clearly outweighs the risks.*)

It is not known whether nitroprusside and its metabolites are excreted in maternal milk.

Overdosage/Acute Toxicity

Acute overdosage is manifested by a profound hypotension. Treat by reducing or stopping the infusion and giving fluids. Monitor blood pressure constantly.

Excessive doses, prolonged therapy, a depleted hepatic thiosulfate (sulfur) supply, or severe hepatic or renal insufficiency may lead to profound hypotension, cyanogen, or thiocyanate toxicity. Acid/base status should be monitored to evaluate therapy and to detect metabolic acidosis (early sign of cyanogen toxicity). Tolerance to therapy is also an early sign of nitroprusside toxicity. Hydroxocobalamin (Vitamin B_{12a}) may prevent cyanogen toxicity. Thiocyanate toxicity may be exhibited as delirium in dogs. Serum thiocyanate levels may need to be monitored in patients on prolonged therapy, especially in those patients with concurrent renal dysfunction. Serum levels >100 micrograms/mL are considered toxic. It is suggested to refer to other references or contact an animal poison control center for further information should cyanogen or thiocyanate toxicity be suspected.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nitroprusside and may be of significance in veterinary patients:

■ **ANESTHETICS, GENERAL:** The hypotensive effects of nitroprusside may be enhanced by concomitant administration of general anesthetics (e.g., **halothane**, **enflurane**), or other circulatory depressants

■ **DOBUTAMINE:** Synergistic effects (increased cardiac output and reduced wedge pressure) may result if dobutamine is used with nitroprusside

■ **HYPOTENSIVE AGENTS, OTHER:** Patients receiving other hypotensive agents (e.g., **beta-blockers**, **ACE inhibitors**, etc.) may be more sensitive to the hypotensive effects of nitroprusside

Doses

Directions for preparation of infusion: Add 2–3 mL D₅W to 50 mg vial to dissolve powder. Add dissolved solution to 1000 mL of D₅W and promptly protect solution from light (using aluminum foil or other opaque covering). Resultant solution contains 50 micrograms/mL of nitroprusside. Higher concentrations may be necessary in treating large animals. The administration set need not be protected from light. Solution may have a slight brownish tint, but discard solutions that turn to a blue, dark red or green color. Solution is stable for 24 hours after reconstitution. Do not add any other medications to IV running nitroprusside. Avoid extravasation at IV site. If using a Mini-Drip IV set (for small animals) (60 drops ≈ 1 mL; 1 drop contains approximately 0.83 micrograms of nitroprusside). Use an accurate flow control device (pump, controller, etc.) for administration.

■ DOGS:

For hypertensive crisis (systolic arterial BP >200 mm Hg):

- a) Initiate dose at 1–2 mcg/kg/minute; increase dosage incrementally every 3–5 minutes until a predetermined target BP is attained. Reduce BP 25% over 4-hour period to allow readaptation of cerebral blood vessels. (Proulx and Dhupa 2000)

For adjunctive treatment of heart failure (cardiogenic shock; fulminant pulmonary edema):

- a) Goal is to decrease or maintain mean arterial pressure to support vital organ functions—approx. 70 mmHg): Dose as above (in “a”); concurrent use of dobutamine (5–10 mcg/kg/min) often indicated. (Proulx and Dhupa 2000)
- b) 0.5–10 mcg/kg/min IV at a low fluid rate (≤2 mL/kg/hr) using D5W or other low sodium fluid. Usually start at 2 mcg/kg/min and increase the base concentration by 1 mcg/kg every 20–30 minutes until there is an improvement in respiratory effort and thoracic auscultation. The patient is maintained on the effective dose for 48 hours. Monitor blood pressure; cyanide poisoning can occur if infusion lasts more than 3 days. After stabilized, drip is tapered as therapy with enalapril is initiated. (Macintire 2006a)
- c) For catastrophic pulmonary edema: As a CRI initiated at 1 mcg/kg/min and carefully titrated to effect by increasing by 1 mcg/kg/min increments every 15 minutes as long as BP remains stable and until perfusion and pulmonary function improves (usually requires between 2–5 mcg/kg/min with the upper limit being 8–10 mcg/kg/min). Maintain most effective dose for 12–15 hours until respiratory distress resolves, lungs are clear, and the patient is stable with a normal blood pressure, pink mucous membranes, normal capillary refill time, and normal heart rate. Most animals at our clinic require 12 hours of treatment. The systolic blood pressure must remain greater than 90 mm Hg. If hypotension develops, the CRI should be stopped. Blood pressure will return to pretreatment levels within 1–10 minutes of discontinuing treatment and administration can be reinstituted at the previous lower dose. Administer with dobutamine to treat or prevent hypotension if severe myocardial failure is present based on an echocardiogram evaluation. Wean sodium nitroprusside over 6 hours first and then dobutamine over 6

hours. ACE inhibitor is added before tapering the infusions over 3–6 hours. (Lichtenberger 2006b)

■ CATS:

For hypertensive crisis (systolic arterial BP >200 mm Hg):

- a) Initiate dose at 0.5 mcg/kg/minute; increase dosage incrementally every 3–5 minutes until a predetermined target BP is attained. Reduce BP 25% over 4-hour period to allow readaptation of cerebral blood vessels. (Proulx and Dhupa 2000)

For adjunctive treatment of heart failure (cardiogenic shock; fulminant pulmonary edema):

- a) Goal to decrease or maintain mean arterial pressure to support vital organ functions—approx. 70 mmHg): Dose as above; concurrent use of dobutamine (1–5 mcg/kg/min) often indicated. (Proulx and Dhupa 2000)
- b) Initiate dose at 0.5 mcg/kg/minute constant rate infusion and increase by 0.5–1 mcg/minute every 5 minutes to desired systolic pressure (90–100 mmHg). Cats are more sensitive to the oxidative damage that can be induced by nitroprusside and total dosages should be kept to a minimum. Use a dedicated line with an infusion pump; IV line and catheter should never be flushed. A nurse devoted for continuous monitoring should be in place during administration. Cover IV solution and IV line with opaque material and discard after 24 hours. (Proulx 2003)
- c) For catastrophic pulmonary edema: As a CRI initiated at 1 mcg/kg/min and carefully titrated to effect by increasing by 1 mcg/kg/min increments every 15 minutes as long as BP remains stable and until perfusion and pulmonary function improves (cats usually requires between 1–2 mcg/kg/min with the upper limit being 2 mcg/kg/min). Maintain most effective dose for 12–15 hours until respiratory distress resolves, lungs are clear, and the patient is stable with a normal blood pressure, pink mucous membranes, normal capillary refill time and normal heart rate. Most animals at our clinic require 12 hours of treatment. The systolic blood pressure must remain greater than 90 mm Hg. If hypotension develops, the CRI should be discontinued. Blood pressure will return to pretreatment levels within 1–10 minutes of discontinuing treatment and administration can be reinstituted at the previous lower dose. Administer with dobutamine to treat or prevent hypotension if severe myocardial failure is present based on an echocardiogram evaluation. Wean sodium nitroprusside over 6 hours first and then dobutamine over 6 hours. ACE inhibitor is added before tapering the infusions over 3–6 hours. (Lichtenberger 2006b)

Monitoring

- Blood pressure must be constantly monitored
- Acid/base balance
- Electrolytes (especially Na⁺)

Client Information

- Must only be used by professionals in a setting where precise IV infusion and constant blood pressure monitoring can be performed.

Chemistry/Synonyms

A vascular smooth muscle relaxant, nitroprusside sodium occurs as practically odorless, reddish-brown crystals or powder. It is freely soluble in water and slightly soluble in alcohol. After reconstitution in D5W, solution may have a brownish, straw, or light orange color and have a pH of 3.5–6.

Nitroprusside sodium may also be known as: disodium (OC-6-22)-pentakis(cyano-C)nitrosylferrate dihydrate, natrii nitroprussias, sodium nitroferrocyanide dihydrate, sodium nitroprusside, or sodium nitroprussiate, and *Nitropress*®.

Storage/Stability/Compatibility

Nitroprusside sodium powder for injection should be stored protected from light and moisture and kept at room temperature (15–30°C). Nitroprusside solutions exposed to light will cause a reduction of the ferric ion to the ferrous ion with a resultant loss in potency and a change from a brownish-color to a blue color. Degradation is enhanced with nitroprusside solutions in *Viaflex*® (Baxter) plastic bags exposed to fluorescent light. After reconstitution, protect immediately by covering vial or infusion bag with aluminum foil or other opaque material. Discard solutions that turn to a blue, dark red, or green color. Solutions protected from light will remain stable for 24 hours after reconstitution. IV infusion tubing need not be protected from light while the infusion is running. It is not recommended to use IV infusion solutions other than D5W or to add any other medications to the infusion solution.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Nitroprusside Sodium Powder for Injection: 50 mg/vial in 2 mL Flip-top vials and 5 mL vials; *Nitropress*® (Abbott); generic; (Elkins-Sinn); (Rx)

NIZATIDINE

(ni-za-ti-dine) Axid®

H₂-RECEPTOR ANTAGONIST; PROKINETIC

Prescriber Highlights

- H₂ receptor antagonist similar to ranitidine; used primarily for its prokinetic activity; may be useful in preventing hemorrhagic necrosis in cats with pancreatitis
- Contraindications: Hypersensitivity to the drug; Caution: Geriatric patients or those with hepatic or renal insufficiency
- Adverse Effects are rare

Uses/Indications

While nizatidine acts similarly to cimetidine and ranitidine as an H₂ blocker to reduce gastric acid secretion in the stomach, in small animal medicine its use has been primarily for its prokinetic effects. It may be useful to treat delayed gastric emptying, pseudo-obstruction of the intestine and constipation.

H₂ blockers may be useful in preventing hemorrhagic necrosis in feline pancreatitis.

Pharmacology/Actions

At the H₂ receptors of the parietal cells, nizatidine competitively inhibits histamine, thereby reducing gastric acid output both during basal conditions and when stimulated by food, amino acids, pentagastrin, histamine, or insulin.

While nizatidine may cause gastric emptying times to be delayed, it more likely will stimulate GI motility by inhibiting acetylcholinesterase (thereby increasing acetylcholine at muscarinic receptors). It may also have direct agonist effects on M₃ muscarinic

receptors. Lower esophageal sphincter pressures may be increased by nizatidine. By decreasing the amount of gastric juice produced, nizatidine decreases the amount of pepsin secreted.

Pharmacokinetics

In the dog, oral absorption is rapid and nearly complete with minimal first pass effect. Food can enhance the absorption of nizatidine, but this is not considered clinically important. The drug is only marginally bound to plasma proteins. It is unknown if it enters the CNS. Nizatidine is metabolized in the liver to several metabolites, including at least one that has some activity. In animals with normal renal function over half the drug is excreted in the urine unchanged.

Contraindications/Precautions/Warnings

Nizatidine is contraindicated in patients who are hypersensitive to it. It should be used cautiously and, possibly, at reduced dosage in patients with diminished renal function. Nizatidine has caused increased serum ALT levels in humans receiving high IV doses for longer than 5 days. The manufacturer recommends that in high dose, chronic therapy, serum ALT values be monitored.

Adverse Effects

Nizatidine appears to be very well tolerated. Very rarely, anemia has been reported in humans taking the drug. CNS effects have been noted (headache, dizziness) but incidence is similar to those taking placebo. Rash and pruritus have also been reported in a few humans taking nizatidine.

Reproductive/Nursing Safety

Doses of up to 275 mg/kg per day in pregnant rabbits did not reveal any teratogenic or fetotoxic effects. Safety during pregnancy not firmly established, so use only when clearly warranted. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Nizatidine is excreted in maternal milk in a concentration of 0.1% of the oral dose in proportion to plasma concentrations and unlikely to cause significant effects in nursing offspring

Overdosage/Acute Toxicity

Single oral doses of up to 800 mg/kg were not lethal in dogs. Adverse effects could include cholinergic effects (lacrimation, salivation, emesis, miosis and diarrhea); suggest treating supportively and symptomatically.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving nizatidine and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS** (atropine, propantheline etc.): May negate the prokinetic effects of nizatidine
- **ASPIRIN**: Nizatidine may increase salicylate levels in patients receiving high doses of aspirin (or other salicylates)

Laboratory Considerations

- False positive tests for **urobilinogen** may occur with patients receiving nizatidine

Doses

■ DOGS:

As a prokinetic agent:

- a) 2.5–5 mg/kg PO once daily (Hall and Washabau 2000)

■ CATS:

As a colonic prokinetic agent:

- a) 2.5–5 mg/kg PO once daily (Washabau and Holt 2000)
- b) In combination with cisapride: nizatidine 2.5–5 mg/kg PO q12h (Scherk 2003b)

Monitoring

- Clinical efficacy (dependent on reason for use); monitored by decrease in symptomatology, endoscopic examination, blood in feces, etc.

Client Information

- To maximize the benefit of this medication, it must be administered as prescribed by the veterinarian; clinical signs may reoccur if dosages are missed.

Chemistry/Synonyms

Nizatidine occurs as an off-white to buff-colored crystalline powder. It has a bitter taste and a slight sulfur-like odor. Nizatidine is sparingly soluble in water.

Nizatidine may also be known as: LY-139037, nizatidinum, and *Axid*®.

Storage/Stability/Compatibility

Nizatidine oral tablets and capsules should be stored in tight, light-resistant containers at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Nizatidine Tablets: 75 mg; *Axid*® AR (Wyeth Consumer); (OTC)

Nizatidine Capsules: 150 mg & 300 mg; *Axid*® *Pulvules* (Lilly); generic; (Rx)

Nizatidine Oral Solution: 15 mg/mL; in 480 mL; *Axid*® (Braintree); (Rx)

NOVOBIOCIN SODIUM

(noe-ve-byeh-oh-sin) Albaplex®

Prescriber Highlights

- Antibiotic primarily effective against some gram-positive cocci
- Contraindications: hypersensitivity to it; Extreme caution: hepatic or hematopoietic dysfunction
- Adverse Effects: Systemic use: Fever, GI (nausea, vomiting, diarrhea), rashes, & blood dyscrasias

Uses/Indications

Novobiocin is approved as a single agent and in combination with penicillin G for use in dry dairy cattle as a mastitis tube. Novobiocin is available in combination with tetracycline and prednisolone for oral use in dogs.

Pharmacology/Actions

Novobiocin is believed to act in several ways in a bactericidal manner. It inhibits bacterial DNA gyrase, interfering with protein and nucleic acid synthesis and also interferes with bacterial cell wall synthesis. Activity of the drug is enhanced in an alkaline medium.

The spectrum of activity of novobiocin includes some gram-positive cocci (Staphs, *Streptococcus pneumoniae*, and some group A streps). Activity is variable against other streptococci and weak against the Enterococci. Most gram-negative organisms are resistant to the drug, but some *Haemophilus* spp., *Neisseria* spp., and *Proteus* spp. may be susceptible.

Pharmacokinetics

After oral administration, novobiocin is well absorbed from the GI tract. Peak levels occur within 1–4 hours. The presence of food can decrease peak concentrations of the drug.

Novobiocin is only poorly distributed to body fluids with concentrations in synovial, pleural, and ascitic fluids less than those found in plasma. Only minimal quantities of the drug cross the blood-brain barrier, even when meninges are inflamed. Highest concentrations of novobiocin are found in the small intestine and liver. The drug is approximately 90% protein bound and is distributed into milk.

Novobiocin is primarily eliminated in the bile and feces. Approximately 3% is excreted into the urine; urine levels are usually less than those found in serum.

Contraindications/Precautions/Warnings

Novobiocin is contraindicated in patients hypersensitive to it. Additionally, the drug should be used with extreme caution in patients with preexisting hepatic or hematopoietic dysfunction.

Adverse Effects

Adverse effects reported with the systemic use of this drug include fever, GI disturbances (nausea, vomiting, diarrhea), rashes, and blood dyscrasias. In humans, occurrences of hypersensitivity reactions, hepatotoxicity, and blood dyscrasias have significantly limited the use of this drug.

Reproductive/Nursing Safety

Safety during pregnancy has not been established; use only when clearly indicated.

Overdosage/Acute Toxicity

Little information is available regarding overdoses of this drug. It is suggested that large oral overdoses be handled by emptying the gut following standard protocols; monitor and treat adverse effects symptomatically if necessary.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving novobiocin and may be of significance in veterinary patients:

- **BETA-LACTAM ANTIBIOTICS:** Novobiocin reportedly acts similarly to probenecid by blocking the tubular transport of drugs. Although the clinical significance of this is unclear, the elimination rates of drugs excreted in this manner (e.g., **penicillins**, **cephalosporins**) could be decreased and half-lives prolonged.

Laboratory Considerations

- Novobiocin can be metabolized into a yellow-colored product that can interfere with **serum bilirubin** determinations.
- Novobiocin may interfere with the determination **BSP** (bromosulfophthalein, sulfobromophthalein) uptake tests by altering BSP uptake or biliary excretion.

Doses

■ DOGS:

- a) For susceptible infections using the combination product (with tetracycline and prednisolone): 22 mg/kg of each antibiotic and 0.55 mg prednisolone PO q12h for 48 hours (Package insert; *Delta Albaplex*®—Upjohn)

■ CATTLE:

- a) For treatment of subclinical mastitis in dry cows: Infuse contents of one syringe into each quarter at the time of drying off; not later than 30 days prior to calving. Shake well before using. (Package directions; *Albadry Plus*®—Pharmacia & Upjohn)
- b) For treatment of mastitis caused by susceptible strains of *Staphylococcal aureas* and *agalactiae* in dry cows: (Package Directions; *Biodry*®—Pharmacia & Upjohn)

Monitoring

- Clinical efficacy
- Adverse effects
- Periodic liver function tests and CBC's are recommended if using long-term systemically.

Client Information

- Shake mastitis tubes well before using
- Do not exceed dosage recommendations or length of treatment

Chemistry/Synonyms

An antibiotic obtained from *Streptomyces niveus* or *spheroides*, novobiocin sodium occurs as white to light yellow, crystalline powder and is very soluble in water.

Novobiocin or novobiocin sodium may also be known as: crystalline acid, PA-93, streptonivcin, U-6591, novobiocinum natrium, sodium novobiocin, *Albadry Plus*®, *Albamycin*®, *Biodry*® and *Delta Albaplex*®.

Storage/Stability

Novobiocin should be stored at room temperature in tight containers unless otherwise directed.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Novobiocin Suspension: 400 mg/10 mL syringe; *Biodry*® (Pfizer); (OTC). Do not use 30 days prior to calving. Slaughter withdrawal (at labeled doses) = 30 days.

Novobiocin Combination Products:

Novobiocin (as the sodium salt): 400 mg and Penicillin G Procaine 200,000 IU per 10 mL *Plaster*® Syringe. *Albadry Plus*® (Pfizer); (OTC). Approved for use in dry cows only. Do not use 30 days prior to calving. Milk must not be used for 72 hours after calving. Slaughter withdrawal (at labeled doses) = 30 days.

Novobiocin Sodium 60 mg, Tetracycline HCl 60 mg and Prednisolone 1.5 mg tablets; Novobiocin Sodium 180 mg, Tetracycline HCl 180 mg and Prednisolone 4.5 mg tablets; *Delta Albaplex*® and *Delta Albaplex*® 3X (Pfizer); (Rx). Approved for use in dogs.

HUMAN-LABELED PRODUCTS: None

NYSTATIN (ORAL)

(nye-stat-in) Nilstat®, Mycostatin®

ANTIFUNGAL (CANDIDA)

Prescriber Highlights

- Oral & topical antifungal (Candida); not absorbed systemically after PO
- Contraindications: Known hypersensitivity
- Adverse Effects: GI effects possible at high dosages; hypersensitivity possible

Uses/Indications

Orally administered nystatin is used primarily for the treatment of oral or gastrointestinal tract *Candida* infections in dogs, cats, and birds; it has been used less commonly in other species for the same indications.

Pharmacology/Actions

Nystatin has a mechanism of action similar to that of amphotericin B. It binds to sterols in the membrane of the fungal cell altering the permeability of the membrane allowing intracellular potassium and other cellular constituents to “leak out.”

Nystatin has activity against a variety of fungal organisms, but is clinically used against topical, oropharyngeal, and gastrointestinal *Candida* infections.

Pharmacokinetics

Nystatin is not measurably absorbed after oral administration and almost entirely excreted unchanged in the feces. The drug is not used parenterally because it is reportedly extremely toxic to internal tissues.

Contraindications/Precautions/Warnings

Nystatin is contraindicated in patients with known hypersensitivity to it.

Adverse Effects

Occasionally, high dosages of nystatin may cause GI upset (anorexia, vomiting, diarrhea). Rarely, hypersensitivity reactions have been reported in humans.

Reproductive/Nursing Safety

Although the safety of the drug during pregnancy has not been firmly established, the lack of appreciable absorption or case reports associating the drug with teratogenic effects appear to make it safe to use. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether nystatin is excreted in maternal milk, but because the drug is not absorbed after oral administration it is unlikely to be of concern.

Overdosage/Acute Toxicity

Because the drug is not absorbed after oral administration, acute toxicity after an oral overdose is extremely unlikely, but transient GI distress may result.

Drug Interactions

No significant interactions reported for oral nystatin

Doses**■ DOGS:**

For oral treatment of Candidal infections:

- 100,000 Units PO q6h (Kirk 1989)
- 50,000–150,000 Units PO q8h (Jenkins and Boothe 1987)
- 22,000 Units/kg/day (Huber 1988b)

■ CATS:

For oral treatment of Candidal infections:

- 100,000 Units PO q6h (Kirk 1989)

■ HORSES:

For intrauterine infusion:

- 250,000–1,000,000 IU; Mix with sterile water; precipitates in saline. Little science is available for recommending doses, volume infused, frequency, diluents, etc. Most intrauterine treatments are commonly performed every day or every other day for 3–7 days. (Perkins 1999)

■ BIRDS:

For crop mycosis and mycotic diarrhea (*Candida albicans*) in chickens and turkeys:

- Feed at 50 grams per ton (*Mycostatin*®-20) or at 100 g/ton for 7–10 days. (Label directions; *Mycostatin*®-20—Solvay)

For enteric yeast (Candidal) infections:

- 200,000–300,000 units/kg PO q8–12h. Relatively large volume must be administered (2–3 mL). May also be used prophylactically to prevent yeast infection in nestling birds treated with broad-spectrum antibiotics. Oral lesions may be missed if bird is tubed. (Flammer 2003a)
- For neonates on antibiotic therapy: Crush one fluconazole 100 mg tablet and mix with 20 mL of nystatin 100,000U/mL oral suspension. Dose at 0.5 mL/1000g of body weight PO twice daily for duration of antibiotic therapy. (Wissman 2003)
- For treatment of candidiasis after antibiotic or in conjunction with antibiotics: One mL of the 100,000 U/mL suspension per 300 g body weight PO 1–3 times daily for 7–14 days. If treating mouth lesions do not give by gavage. Hand-fed babies should receive antifungal therapy if being treated with antibiotics. (Clubb 1986)

Ratites:

- 250,000–500,000 IU/kg PO twice daily (Jenson 1998)

■ REPTILES:

For susceptible infections:

- For turtles with enteric yeast infections: 100,000 IU/kg PO once daily for 10 days (Gauvin 1993)
- All species: 100,000 units/kg PO once daily (Jacobson 1999)

Monitoring

- Clinical efficacy

Client Information

- Shake suspension well before administering

Chemistry/Synonyms

A polyene antifungal antibiotic produced by *Streptomyces noursei*, nystatin occurs as a yellow to light tan, hygroscopic powder having a cereal-like odor. It is very slightly soluble in water and slightly to sparingly soluble in alcohol. One mg of nystatin contains not less than 4400 Units of activity. According to the USP, nystatin used in

the preparation of oral suspensions should not contain less than 5000 Units per mg.

Nystatin may also be known as: fungicidin, nistatina, or nystatinum, *Mycostatin*®, and *Nilstar*®.

Storage/Stability

Nystatin tablets and oral suspension should be stored at room temperature (15–30°C) in tight, light-resistant containers. Avoid freezing the oral suspension or exposing to temperatures greater than 40°C.

Nystatin deteriorates when exposed to heat, light, air or moisture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

None, for oral use. For topical use, see the topical dermatologic section in the appendix.

HUMAN-LABELED PRODUCTS:

Nystatin Oral Suspension: 100,000 Units/mL in 5 mL, 60 mL, 473 mL and 480 mL; *Nilstar*® (Lederle); generic; (Rx)

Nystatin Bulk powder: 50 million, 150 million, 500 million units, 1 billion, 2 billion and 5 billion units; generic; (Paddock); *Nilstar*® (Lederle); (Rx)

Nystatin Oral Tablets: 500,000 Units; *Mycostatin*® (Bristol-Myers Squibb), generic; (Rx)

Also available in oral troches, vaginal tablets, topical creams, powders and ointments.

OCTREOTIDE ACETATE

(ok-trye-oh-tide) Sandostatin®

SOMATOSTATIN ANALOG

Prescriber Highlights

- ▶ Injectable long acting somatostatin analog that may be useful for adjunctive treatment of insulinomas & gastrinomas
- ▶ Limited experience, but appears safe
- ▶ Multiple daily SC injections are required
- ▶ No information for veterinary use of depot IM form
- ▶ Expensive (especially in large dogs)
- ▶ May affect GI fat absorption

Uses/Indications

Octreotide may be useful in the adjunctive treatment of hyperinsulinemia in patients with insulinomas (especially dogs, ferrets). Response is variable, presumably dependent on whether the tumor cells have receptors for somatostatin. Octreotide may also be useful in the diagnosis and symptomatic treatment of gastrinomas in dogs or cats. It may be of use in the treatment of acute pancreatitis, but more research is needed before it can be recommended for this use in veterinary patients.

Pharmacology/Actions

Octreotide is a synthetic long acting analog of somatostatin. It inhibits the secretion of insulin (in both normal and neoplastic beta cells), glucagon, secretin, gastrin and motilin. In humans, octreotide may bind to any one of 5 subtypes of somatostatin receptors found on neoplastic beta cells, but dogs only have one subtype. This, or

octreotide's inhibition of glucagon and growth hormone secretion, may explain the variable response dogs have to treatment.

Pharmacokinetics

Octreotide is absorbed and distributed rapidly from the injection site after SC administration. Half lives in humans average about 2 hours with duration of effect up to 12 hours. Treated dogs or ferrets generally require 2–3 injections per day to maintain blood glucose. About 32% of a dose is excreted unchanged in the urine and patients with severe renal dysfunction may need dosage adjustment.

Contraindications/Precautions/Warnings

Octreotide is contraindicated in patients hypersensitive to it. It should be used with caution in patients with biliary tract disorders.

Adverse Effects

Very limited experience in domestic animals, although it appears to be well tolerated thus far. GI effects (including biliary tract effects) are most commonly noted in human patients, particularly acromegals.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether this drug is excreted in maternal milk.

Overdosage/Acute Toxicity

Serious adverse effects are unlikely. Human subjects have received up to 120 mg IV over 8 hours with no untoward effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving octreotide and may be of significance in veterinary patients:

- **BETA-BLOCKERS:** Octreotide may cause additive bradycardic effects
- **BROMOCRIPTINE:** Octreotide may increase oral bioavailability
- **CALCIUM-CHANNEL BLOCKERS:** Octreotide may cause additive bradycardic effects
- **CYCLOSPORINE:** Octreotide may reduce cyclosporine levels
- **DIURETICS (and other agents that affect fluid/electrolyte balance):** Octreotide may enhance fluid/electrolyte imbalances
- **FOOD:** Octreotide may reduce fat absorption
- **INSULIN, ORAL HYPOGLYCEMICS:** Octreotide may can inhibit insulin
- **QUINIDINE:** Octreotide may reduce the quinidine clearance

Doses

■ Dogs:

For medical treatment of insulinoma (particularly in patients refractory to or unable to tolerate other medical or surgical therapy):

- a) 10–40 mcg (total dose per dog) SC 2–3 times a day. Used in combination with dietary, glucocorticoid, and diazoxide treatment. (Nelson 2000)
- b) Further studies needed to determine octreotide's efficacy and safety; has been administered at 2–4 mcg/kg SC q8–12h (Hess 2005)

For adjunctive treatment of gastrinoma:

- a) 2–20 mcg/kg SC three times daily; with omeprazole. (Simpson 2005)
- b) 2–8 mcg/kg SC q8–12h

For adjunctive treatment of chylothorax:

- a) 10–20 mcg/kg SC three times a day for 2–3 weeks; prolonged treatment should be discouraged because people treated for longer than 4 weeks are at risk for gallstones. (Fossom 2006)

■ CATS:

For adjunctive treatment of chylothorax:

- a) 10–20 mcg/kg SC three times a day for 2–3 weeks; prolonged treatment should be discouraged because people treated for longer than 4 weeks are at risk for gallstones. (Fossom 2006)

■ FERRETS:

For medical treatment of insulinoma (particularly in patients refractory to or unable to tolerate other medical or surgical therapy):

- a) 1–2 mcg/kg SC 2–3 times a day (Meleo and Caplan 2000)

Monitoring

- Blood glucose (for insulinoma treatment)
- Clinical efficacy

Client Information

- There is very limited experience with this medication in dogs and ferrets and therapy must be considered experimental.
- Injections must be given 2–3 times a day per veterinarian instructions
- The expense associated with this medication can be considerable.

Chemistry/Synonyms

Octreotide acetate is a synthetic polypeptide related to somatostatin. It is commercially available in injectable forms for subcutaneous or IV injection, and as an extended release suspension for IM administration.

Octreotide acetate may also be known as: SMS-201-995, *Longastatina*®, *Samilstin*®, *Sandostatin*®, *Sandostatina*®, or *Sandostatine*®.

Storage/Stability

When stored at room temperature and protected from light, octreotide acetate injection remains stable for 14 days. For long-term storage, keep refrigerated. If injecting solution that has been in the refrigerator, allow it to come to room temperature in the syringe before injecting. Do not use artificial warming techniques. It is recommended to use multidose vials within 14 days of initial use.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Octreotide Acetate for Injection: 0.05 mg/mL, 0.1 mg/mL, 0.2 mg/mL, 0.5 mg/mL 1 mg/mL in 1 mg amps, single-dose vials and 5 mL multi-dose vials; *Sandostatin*® (Novartis); generic (Sicor); (Rx)

Octreotide Acetate Powder for Injectable Suspension: 10 mg/5 mL, 20 mg/5 mL, 30 mg/5 mL in kits with 2 mL diluent and 1–1/2" 20-gauge needle; *Sandostatin*® LAR Depot (Novartis); (Rx)

OLSALAZINE SODIUM

(ole-sal-a-zeen) Dipentum®

ANTIINFLAMMATORY (LOCAL GI TRACT)

Prescriber Highlights

- Used for treatment of chronic colitis in dogs that either are unresponsive to or cannot tolerate sulfasalazine
- Keratoconjunctivitis sicca (KCS) has been reported in some dogs
- Converted to 2 molecules of 5-ASA (mesalamine) in colon
- Limited experience in dogs
- Expensive when compared to sulfasalazine

Uses/Indications

Olsalazine is used for treatment of dogs with chronic colitis that either cannot tolerate the adverse effects associated with sulfasalazine or the response to sulfasalazine has been ineffective.

Pharmacology/Actions

Olsalazine is cleaved in the intestine into 5-aminosalicylic acid (5-ASA, mesalamine) by bacteria in the gut. While its exact mechanism is unknown, mesalamine is thought to have efficacy for chronic colitis secondary to its antiinflammatory activity.

Pharmacokinetics

Olsalazine is poorly absorbed; approximately 98% of a dose reaches the colon intact and what drug is absorbed is rapidly eliminated. Serum half-life is about one hour.

Contraindications/Precautions/Warnings

Olsalazine is contraindicated in patients hypersensitive to it or to salicylates. Use with caution in animals with renal disease as renal toxicity has developed, though rarely, in human patients.

Adverse Effects

While keratoconjunctivitis sicca (KCS) is occasionally reported in dogs receiving olsalazine, it probably occurs less frequently than with sulfasalazine therapy. In humans, approximately 17% of patients developed more serious diarrhea (then they had prior to treatment) after receiving olsalazine.

Reproductive/Nursing Safety

In high dose rat studies, some fetal abnormalities were seen. Use during pregnancy only when benefits outweigh the risks. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Oral olsalazine given to lactating rats in doses 5–20 times the human dose produced growth retardation in their pups. Use with caution in nursing patients.

Overdosage/Acute Toxicity

Overdosage in dogs may cause vomiting, diarrhea and decreased motor activity; treat symptomatically and supportively. Dosages up to 2 g/kg were not lethal in dogs.

Drug Interactions

The following drug interaction has either been reported or are theoretical in humans or animals receiving omeprazole and may be of significance in veterinary patients:

- **WARFARIN:** Omeprazole may increase prothrombin times in patients receiving warfarin

Laboratory Considerations

- Omeprazole may cause increases in **ALT** or **AST**

Doses

■ DOGS:

- For dogs who cannot tolerate omeprazole: 10–20 mg/kg PO three times daily (Leib 2000)
- When response is poor to initial omeprazole therapy: 11 mg/kg PO twice daily (Tams 2000)
- 10–15 mg/kg PO q8–12h (Hall 2004)
- Initially at 5–10 mg/kg PO three times daily, then reduce gradually. (Allensbach 2005)

Monitoring

- Clinical efficacy
- Adverse effects

Client Information

- Should be given with food in evenly spaced doses (if possible)
- If diarrhea worsens or dogs eyes become dry, contact veterinarian

Chemistry/Synonyms

Omeprazole sodium occurs as a yellow crystalline powder that is soluble in water and stable under physiologic acidic and alkaline conditions. It is basically 2 molecules of mesalamine (5-ASA) connected at the azo bonding site.

Omeprazole sodium may also be known as: azodisal sodium, dimesalamine, CI mordant yellow 5, CI No. 14130, CJ-91B, omeprazole sodium, sodium azodisalicylate, *Dipentum*® or *Rasal*®.

Storage/Stability

Store capsules at room temperature.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 4 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Omeprazole Sodium Capsules: 20 mg; *Dipentum*® (Celltech); (Rx)

OMEPRAZOLE

(oh-meh-prah-zahl) Gastroguard®, Prilosec®

PROTON PUMP INHIBITOR

Prescriber Highlights

- Proton pump inhibitor used for GI ulcers & erosions
- Contraindications: Known hypersensitivity; may need to adjust dosage with hepatic or renal disease
- Adverse Effects: **HORSES:** Unlikely; potential hypersensitivity. **SMALL ANIMALS:** Appears to be well tolerated. Potentially: GI distress (anorexia, colic, nausea, vomiting, flatulence, diarrhea), hematologic abnormalities, urinary tract infections, proteinuria, or CNS disturbances
- Treatment is relatively expensive, but human generics are now available & costs are decreasing for small animals

Uses/Indications

Omeprazole is potentially useful in treating both gastroduodenal ulcer disease and to prevent or treat gastric erosions caused by ulcerogenic drugs (e.g., aspirin). An oral paste product is labeled for the treatment and prevention of recurrence of gastric ulcers in horses.

Pharmacology/Actions

Omeprazole is a substituted benzimidazole gastric acid (proton) pump inhibitor. In an acidic environment, omeprazole is activated to a sulphenamide derivative that binds irreversibly at the secretory surface of parietal cells to the enzyme, H⁺/K⁺ ATPase. There it inhibits the transport of hydrogen ions into the stomach. Omeprazole reduces acid secretion during both basal and stimulated conditions. Omeprazole also inhibits the hepatic cytochrome P-450 mixed function oxidase system (see Drug Interactions below).

Pharmacokinetics

Omeprazole is rapidly absorbed from the gut; the human commercial product is in an enteric-coated granule form as the drug is rapidly degraded by acid. The equine paste is not enteric coated. In humans, peak serum levels occur within 0.5–3.5 hours and onset of action within 1 hour. Omeprazole is distributed widely, but primarily in gastric parietal cells. In humans, approximately 95% is bound to albumin and alpha₁-acid glycoprotein. It is unknown whether omeprazole enters maternal milk.

Omeprazole is extensively metabolized in the liver to at least six different metabolites. These are excreted principally in the urine, but also via the bile into feces. Significant hepatic dysfunction will reduce the first pass effect of the drug. In humans and dogs with normal hepatic function, serum half-life averages about 1 hour, but the duration of therapeutic effect may persist for 24–72 hours or more. Effects on acid production in horses can last up to 27 hours, depending upon dose.

Contraindications/Precautions/Warnings

Omeprazole is contraindicated in patients hypersensitive to it. In patients with hepatic or renal disease, the drug's half-life may be prolonged and dosage adjustment may be necessary if the disease is severe.

Adverse Effects

The manufacturer does not note any adverse effects for use in horses at labeled dosages. There is an anecdotal case report of one horse developing urticaria after receiving omeprazole. The drug appears to be quite well tolerated in both dogs and cats at effective dosages. Potentially, GI distress (anorexia, colic, nausea, vomiting, flatulence, diarrhea) could occur, as well as hematologic abnormalities (rare in humans), urinary tract infections, proteinuria, or CNS disturbances. Chronic very high doses in rats caused enterochromaffin-like cell hyperplasia and gastric carcinoid tumors; effects occurred in dose related manner. The clinical significance of these findings for long-term low-dose clinical usage is not known, however, at the current time in humans, dosing for longer than 8 weeks is rarely recommended unless the benefits of therapy outweigh the potential risks. In dogs, omeprazole use is believed safe for at least 4 weeks of therapy. Treatment of horses for up to 90 days is believed safe.

Reproductive/Nursing Safety

Omeprazole's safety during pregnancy has not been established, but a study done in rats at doses of up to 345 times those recommended did not demonstrate any teratogenic effects; however, increased embryo–lethality has been noted in lab animals at very high dosages. In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

It is not known whether these agents are excreted in maternal milk. In rats, omeprazole administration during late gestation and lactation at doses of 35–345 times the human dose resulted in decreased weight gain in pups. In humans, because of the potential for serious adverse reactions in nursing infants, and the potential for tumorigenicity shown in rat carcinogenicity studies, nursing is discouraged if the drug is required.

Overdosage/Acute Toxicity

The LD₅₀ in rats after oral administration is reportedly >4 g/kg. Humans have tolerated oral dosages of 360 mg/day without significant toxicity. Should a massive overdose occur, treat symptomatically and supportively.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving omeprazole and may be of significance in veterinary patients:

- **BENZODIAZEPINES:** Omeprazole may potentially alter benzodiazepine metabolism and prolong CNS effects
- **CLARITHROMYCIN:** Increased levels of omeprazole, clarithromycin and 14-hydroxylclarithromycin are possible
- **CYANOCOBALAMIN (oral):** Omeprazole may decrease oral absorption
- **CYCLOSPORINE:** Omeprazole may reduce cyclosporine metabolism
- **DRUGS REQUIRING DECREASED GASTRIC PH FOR OPTIMAL ABSORPTION** (e.g., ketoconazole, itraconazole, iron, ampicillin esters): Omeprazole may decrease drug absorption
- **SUCRALFATE:** May decrease bioavailability of orally administered omeprazole
- **WARFARIN:** Omeprazole may increase anticoagulant effect

Laboratory Considerations

- Omeprazole may cause increased **liver enzymes**
- Omeprazole will increase **serum gastrin** levels early in therapy

Doses

Dose dependent on formulation, equine paste and human oral forms may not be interchangeable. Be wary of compounded formulations; bioequivalence is not assured.

■ DOGS:

For ulcer management:

- a) 0.5–1 mg/kg PO once daily (Davenport 1992); (Haskins 2000)
- b) For adjunctive treatment of uremic gastropathy: 0.5–1 mg/kg PO q24h; dosage may need to be modified in moderate or severe renal failure. (Vaden 2007)
- c) For severe ulceration unresponsive to H₂ blockers; severe esophagitis unresponsive to metoclopramide and H₂ blockers; gastrinoma (Zollinger-Ellison syndrome): 0.75–1 mg/kg PO once daily (q24h) –OR– one 20 mg capsule for animals >20 kg, 10 mg (1/2 capsule) for animals weighing >5 kg but <20 kg, 5 mg (1/4 capsule) for animals weighing <5 kg. When using less than a full capsule, repackage granules in a gelatin capsule to avoid gastric acid degradation. (Johnson, Sherding et al. 1994)
- d) 0.7 mg/kg (>20 kg, 20 mg/dog; <20 kg, 10 mg/dog) PO once daily (Matz 1995)
- e) For adjunctive treatment of esophagitis or gastric ulcers: 0.5–1 mg/kg PO q24h (Sellon 2007a), (Sellon 2007b)
- f) For some animals with gastrinomas or esophagitis (often H-2 receptor antagonists are adequate): 0.7–1.5 mg/kg PO q24h, but if severe esophagitis or gastrinomas may use up to 2 mg/kg PO q12h (Willard 2006d)
- g) For eliminating *Helicobacter* gastritis infections: Using triple therapy: Metronidazole 33 mg/kg once daily, amoxicillin 11 mg/kg q12h and either sucralfate (0.25–0.5 grams q8h) or **omeprazole** 0.66 mg/kg once daily (Hall 2000)

■ CATS:

For ulcer management:

- a) 0.7 mg/kg PO once a day (Johnson 1996)
- b) 0.7–1.5 mg/kg PO q12–24h (Willard 2003b)
- c) For adjunctive treatment of esophagitis or gastric ulcers: 0.5–1 mg/kg PO q24h (Sellon 2007a), (Sellon 2007b)
- d) For adjunctive treatment of uremic gastropathy: 0.7 mg/kg PO q24h; dosage may need to be modified in moderate or severe renal failure. (Vaden 2007)

■ HORSES: (Note: ARCI UCGFS Class 5 Drug)

For gastric ulcers:

- a) For treatment of gastric ulcers: 4 mg/kg PO once daily for 4 weeks; to prevent recurrence treat for at least another 4 weeks at 2 mg/kg PO once daily (Label Directions; *Gastrogard*®)
- b) 4 mg/kg PO once daily for treatment; 2 mg/kg PO once daily to prevent recurrence in Thoroughbreds in race training (Andrews and Nadeau 1999)
- c) For treatment or prophylaxis of gastric ulcers in foals: 4 mg/kg PO once daily for treatment, 1–2 mg/kg PO once daily for prophylaxis (Wilkins 2004b)

■ SWINE:

For ulcer management:

- a) 40 mg of PO daily for two days; fasted for 48 hours (DeMint 1999)

Monitoring

- Efficacy
- Adverse effects

Client Information

- Give before meals, preferably in the morning

Chemistry/Synonyms

A substituted benzimidazole proton pump inhibitor, omeprazole has a molecular weight of 345.4 and pK_a 's of 4 and 8.8.

Omeprazole may also be known as: H-168/68, or omeprazolium, *Gastrogard*®, *Prilosec*®, *Ulcergard*® and *Zegerid*®.

Storage/Stability

Omeprazole oral paste should be stored below 86°F. Transient exposure to temperatures up to 104°F is permitted. Omeprazole tablets should be stored at room temperature in light-resistant, tight containers. Omeprazole pellets found in the capsules are fragile and should not be crushed. If needed to administer as a slurry, it has been suggested to mix the pellets carefully with fruit juices, not water, milk or saline.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Omeprazole Oral Paste, 2.28g per syringe; *Gastrogard*® (Merial), (Rx); *Ulcergard*® (Merial), (OTC)

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Omeprazole Oral Delayed-Release Capsules: 10 mg, 20 mg (tablets & capsules) & 40 mg; *Prilosec*® (AstraZeneca); *Prilosec*® OTC (*Losec*® in Canada) (*Procter & Gamble*); generic; (Rx & OTC)

Omeprazole/Sodium Bicarbonate Oral Capsules (Immediate Release): 20 mg omeprazole/1,100 mg sodium bicarbonate; 40 mg omeprazole/1,100 mg sodium bicarbonate; *Zegerid*® (Santarus); (Rx)

Omeprazole/Sodium Bicarbonate Powder for Oral Suspension: 20 mg omeprazole/1,680 sodium bicarbonate; 40 mg omeprazole/1,680 sodium bicarbonate; in 30 unit-dose packets; *Zegerid*® (Santarus); (Rx)

ONDANSETRON HCL

(on-dan-sah-tron) Zofran®

5-HT₃ RECEPTOR ANTAGONIST

Prescriber Highlights

- ▶ 5-HT₃ receptor antagonist for severe vomiting
- ▶ Appears to be well tolerated in dogs
- ▶ Generic dosage forms now available

Uses/Indications

Used as an antiemetic when conventional antiemetics are ineffective, such as when administering cisplatin or for other causes of intractable vomiting. The use of ondansetron in cats is somewhat controversial and some state it should not be used in this species.

Pharmacology/Actions

Ondansetron is a 5-HT₃ (serotonin type 3) receptor antagonist. 5-HT₃ receptors are found peripherally on vagal nerve terminals and centrally in the chemoreceptor trigger zone (CTZ). It is not clear if ondansetron's effects are mediated centrally, peripherally or both.

Pharmacokinetics

No veterinary species data was located for ondansetron pharmacokinetics. In humans, ondansetron is well absorbed from the GI tract, but exhibits some first pass hepatic metabolism. Bioavailability is about 50–60%. Peak plasma levels occur about 2 hours after an oral dose. Ondansetron is extensively metabolized in the liver. Elimination half-lives are about 3–4 hours, but are prolonged in elderly patients.

Contraindications/Precautions/Warnings

Ondansetron is contraindicated in patients hypersensitive to it or other agents in this class. Ondansetron may mask ileus or gastric distention; it should not be used in place of nasogastric suction. Use with caution in patients with hepatic dysfunction as half-life may be prolonged.

Because ondansetron is potentially a neurotoxic substrate of P-glycoprotein, it should be used with caution in those herding breeds (e.g., Collies, Shelties, Australian shepherds, etc.) that may have the gene mutation that causes a nonfunctional protein.

Adverse Effects

Ondansetron appears to be well tolerated. Constipation, extrapyramidal clinical signs, arrhythmias and hypotension are possible (incidence in humans <10%).

Reproductive/Nursing Safety

Safety in pregnancy not clearly established, but high dose studies in rodents did not demonstrate overt fetal toxicity or teratogenicity. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Ondansetron is excreted in the maternal milk of rats. Exercise caution when 5-HT₃ antagonists are administered to nursing patients.

Overdosage/Acute Toxicity

Overdoses of up to 10X did not cause significant morbidity in human subjects. If an overdose occurs, treat supportively.

Drug Interactions/Laboratory Considerations

None reported

Doses

■ DOGS:

- As an antiemetic for adjunctive treatment of pancreatitis: 0.1–0.2 mg/kg IV slowly (Webb 2007a)
- As an antiemetic when conventional antiemetics are ineffective: 0.1–1 mg/kg PO q12–24h, or 30 minutes prior to and 90 minutes after starting cisplatin infusion (Frimberger 2000)
- For intractable vomiting associated with Parvo enteritis: 0.11–0.176 mg/kg IV given as a slow IV push every 6–12 hours (based on patient response) (Tams 2003d)
- As an antiemetic: 0.1–0.2 mg/kg IV q6–12h or 0.1–1 mg/kg PO q12–24h (Otto 2005)
- As an antiemetic for adjunctive treatment of uremia: 0.6–1 mg/kg PO or IV q12h; usually combined with metoclopramide. (Polzin 2005a)

■ CATS:

- For intractable vomiting when other less expensive drugs are ineffective: 0.22 mg/kg (route not identified) 2–3 times a day (Willard 1999)
- As an anti-emetic for intractable vomiting: 0.1–0.15 mg/kg slow IV push q6–12h as needed (Scherk 2003c)
- As an antiemetic for adjunctive treatment of severe pancreatitis: 0.1–1 mg/kg PO or IV q12–24h (Armstrong 2007)

Monitoring

- Clinical efficacy

Client Information

- This medication is generally used in inpatient settings for treatment of serious vomiting.

Chemistry/Synonyms

A selective inhibitor of serotonin type 3 (5-HT₃), ondansetron HCl dihydrate occurs as a white to off-white powder that is soluble in water.

Ondansetron HCl may also be known as: GR-38032F or ondansetroni hydrochloridum, and *Zofran*®.

Storage/Stability

Unless otherwise labeled, store oral products in tight, light-resistant containers between 2–30°C. The injection should be stored between 2–30°C and protected from light.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Ondansetron HCl Tablets: 4 mg, 8 mg and 24 mg; *Zofran*® (GlaxoSmithKline), generic; (Rx)

Ondansetron Orally Disintegrating Tablets: 4 mg & 8 mg (as base); *Zofran*® ODT (GlaxoSmithKline), generic; (Rx)

Ondansetron HCl Oral Solution: 4 mg/5 mL (5 mg as the HCl) in 50 mL bottles; *Zofran*® (GlaxoSmithKline), generic; (Rx)

Ondansetron HCl Injection: 2 mg/mL in 2 mL single-dose and 20 mL multi-dose vials, and 32 mg/50 mL (premixed; preservative free) in 50 mL single-dose containers; *Zofran*® (GlaxoSmithKline); generic; (Rx)

ORBIFLOXACIN

(or-bi-flox-a-sin) Orbax®

FLUOROQUINOLONE ANTIBIOTIC

Prescriber Highlights

- ▶ Fluoroquinolone antibiotic labeled for dogs & cats
- ▶ Contraindications: Immature dogs during the rapid growth phase; known hypersensitivity to this class of drugs. Caution: Known or suspected CNS disorders
- ▶ Adverse Effects: GI effects most likely
- ▶ Drug Interactions

Uses/Indications

Orbifloxacin is indicated for treatment in dogs and cats for bacterial infections susceptible to it. Orbifloxacin may also be of benefit in treating susceptible gram-negative infections in horses.

Pharmacology/Actions

Orbifloxacin is a concentration-dependent bactericidal agent. It acts by inhibiting bacterial DNA-gyrase (a type-II topoisomerase), thereby preventing DNA supercoiling and DNA synthesis. The net result is disruption of bacterial cell replication.

Orbifloxacin has good activity against many gram-negative and gram-positive bacilli and cocci, including most species and strains of *Klebsiella* spp., *Staphylococcus intermedius* or *aureus*, *E. coli*, *Enterobacter*, *Campylobacter*, *Shigella*, *Proteus*, *Pasturella* species. Some strains of *Pseudomonas aeruginosa* and *Pseudomonas* spp. are resistant to orbifloxacin and most *Enterococcus* spp. are resistant. Like other fluoroquinolones, orbifloxacin has weak activity against most anaerobes and is not a good choice when treating known or suspected anaerobic infections.

Pharmacokinetics

After oral administration in dogs or cats, orbifloxacin is apparently nearly completely absorbed. The drug is distributed well ($V_d=1.5$ L/kg in dogs and 1.4 L/kg in cats) and only bound slightly to plasma proteins (8% dogs; 15% cats). Orbifloxacin is eliminated primarily via the kidneys. Approximately 50% of the drug is excreted unchanged. Serum half-life is about 6 hours in both dogs and cats. Urine levels remain well above MIC's for susceptible organisms for at least 24 hours after dosing.

In horses, orbifloxacin is well absorbed after oral administration (bioavailability is about 70%) and distributes in many body fluids and endometrial tissue. Elimination half-life is approximately 9 hours.

Contraindications/Precautions/Warnings

Orbifloxacin, like other fluoroquinolones, can cause arthropathies in immature, growing animals. Because dogs appear to be more sensitive to this effect, the manufacturer states that the drug is contraindicated in immature dogs during the rapid growth phase (between 2–8 months in small and medium-sized breeds and up to 18 months in large and giant breeds). The drug is also contraindicated in dogs and cats known to be hypersensitive to orbifloxacin or other drugs in its class (quinolones).

The manufacturer states that orbifloxacin should be used with caution in animals with known or suspected CNS disorders (e.g., seizure disorders) as, rarely, drugs in this class have been associated with CNS stimulation.

Adverse Effects

While the manufacturer reports that no adverse effects were reported during clinical studies (at 2.5 mg/kg dosing) in adult animals, higher doses or additional experience with use of the drug may demonstrate additional adverse effects. Gastrointestinal effects (anorexia, vomiting, diarrhea) would most likely be the first adverse effects noted.

Ophthalmic adverse effects are not likely in cats, but the FDA's Adverse Drug Reaction database has received 10 reports (as of July 3, 2007) of blindness associated with orbifloxacin. Causal effect cannot be proven, but use higher dosages carefully.

Reproductive/Nursing Safety

Safety in breeding or pregnant dogs or cats has not been established. It is not known whether orbifloxacin enters maternal milk.

Overdosage/Acute Toxicity

Dogs and cats receiving up to 5X (37.5mg/kg) for 30 days did not result in any significant adverse effects. Cats receiving the higher dosages exhibited soft feces and decreased body weight gains.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving orbifloxacin or related fluoroquinolones and may be of significance in veterinary patients:

- **ANTACIDS/DAIRY PRODUCTS:** Containing cations (Mg^{++} , Al^{+++} , Ca^{++}) may bind to orbifloxacin and prevent its absorption; separate doses of these products by at least 2 hours
- **ANTIBIOTICS, OTHER (aminoglycosides, 3rd-generation cephalosporins, penicillins—extended-spectrum:** Synergism may occur, but is not predictable, against some bacteria (particularly *Pseudomonas aeruginosa*) with these compounds. Although orbifloxacin has minimal activity against anaerobes, *in vitro* synergy has been reported when used with **clindamycin** against strains of *Peptostreptococcus*, *Lactobacillus* and *Bacteroides fragilis*.
- **CYCLOSPORINE:** Fluoroquinolones may exacerbate the nephrotoxicity, and reduce the metabolism of, cyclosporine (used systemically)
- **FLUNIXIN:** Has been shown in dogs to increase the AUC and elimination half-life of enrofloxacin and enrofloxacin increases the AUC and elimination half-life of flunixin; it is unknown if orbifloxacin also causes this effect or if other NSAIDs interact with orbifloxacin in dogs
- **GLYBURIDE:** Severe hypoglycemia possible
- **IRON, ZINC (oral):** Decreased orbifloxacin absorption; separate doses by at least two hours
- **METHOTREXATE:** Increased MTX levels possible with resultant toxicity
- **NITROFURANTOIN:** May antagonize the antimicrobial activity of the fluoroquinolones and their concomitant use is not recommended
- **PHENYTOIN:** Orbifloxacin may alter phenytoin levels
- **PROBENECID:** Blocks tubular secretion of ciprofloxacin and may also increase the blood level and half-life of orbifloxacin
- **SUCRALFATE:** May inhibit absorption of orbifloxacin; separate doses of these drugs by at least 2 hours
- **THEOPHYLLINE:** Orbifloxacin may increase theophylline blood levels
- **WARFARIN:** Potential for increased warfarin effects

Doses

■ DOGS & CATS:

For susceptible infections:

- a) 2.5 mg/kg–7.5 mg/kg, once daily PO. Higher end of the dosing range may be necessary in hospitalized patients, those with underlying disease (e.g., malignancy) or structural alterations (e.g., burns, complicated urinary tract infections, foreign body infections), infections associated with vascular compromise and infections caused by “problem” pathogens. (Package Insert; *Orbax*®)

■ HORSES:

For susceptible infections:

- a) 5 mg/kg, once daily PO (Davis, Papich et al. 2006)
- b) 7.5 mg/kg PO once daily (Haines, Brown et al. 2001)

Monitoring/Client Information

- Efficacy is the most important monitoring parameter
- Clients should be instructed on the importance of giving the medication as instructed and not to discontinue it on their own.

Chemistry/Synonyms

A 4-fluoroquinolone antibiotic, orbifloxacin is slightly soluble in water at neutral pH. Solubility increases in either an acidic or basic medium.

Orbifloxacin may also be known as marufloxacin or *Orbax*®.

Storage/Stability/Compatibility

The commercially available tablets should be stored between 2–30°C (36–86°F) and protected from excessive moisture.

An orbifloxacin 22.7 mg tablet crushed and mixed with molasses, dark corn syrup, water from canned tuna, Kame fish sauce, *Ora-Plus*, *Syrplata*, or simple syrup was relatively stable (>85% expected value) for up to 7 days when stored unrefrigerated, but protected from light. Mixing with oral supplements that contain calcium or magnesium (e.g., *Lixotinic*) showed significant inactivation of orbifloxacin by 4 days (Kukanich and Papich 2003).

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Orbifloxacin Oral Tablets: 5.7 mg (yellow) in btl of 250; 22.7 mg (green; E-Z Break) in btl of 250; 68 mg (blue; E-Z Break) in btl of 100; *Orbax*® (Schering-Plough Animal Health); (Rx). Approved for use in dogs and cats. Federal law prohibits the use of the drug in food-producing animals.

HUMAN-LABELED PRODUCTS: None

Ormetoprim—see Sulfadimethoxine/Ormetoprim

OSELTAMIVIR PHOSPHATE

(oh-sell-*tam*-ih-vir) Tamiflu®

NEURAMINIDASE INHIBITOR ANTIVIRAL

Prescriber Highlights

- Neuraminidase inhibitor antiviral for influenza A & B viruses; anecdotally, may be effective for parvovirus infections in dogs or other mixed bacterial/viral infections
- Very limited information on efficacy & safety in animals
- Due to public health issues, use in veterinary medicine is controversial
- Expense an issue, especially for treating horses

Uses/Indications

Although, there is no research published (at the time of writing—January 2007) documenting oseltamivir safety or efficacy in dogs or cats, there is much interest and discussion regarding its potential for the adjunctive treatment of parvovirus infections in dogs. It may be of benefit for adjunctive treatment of other viral infections, particularly those with associated secondary bacterial components, but research or experience is lacking. A recent study performed in horses, experimentally infected with equine influenza A (H3N8), documented some efficacy in the attenuation of clinical signs (pyrexia), viral shedding, and secondary bacterial pneumonias (Yamanaka, Tsujimura et al. 2006).

Because oseltamivir is the primary antiviral agent proposed for treatment or prophylaxis for an H5N1 influenza ("bird flu") pandemic in humans, its use in veterinary patients is controversial, particularly due to concerns of adequate drug supply for the human population and the potential for influenza virus resistance development. In 2006, the FDA banned the extra-label use of oseltamivir and other influenza antivirals in chickens, turkeys and ducks. At the time of writing, its use is still allowed in mammal veterinary patients, but veterinarians should use the drug prudently and be cognizant of these public health concerns.

Pharmacology/Actions

Oseltamivir phosphate is a prodrug that is converted after absorption into oseltamivir carboxylate, the active form of the drug. Oseltamivir carboxylate competitively inhibits influenza virus neuraminidase, an enzyme that is required for viral replication, release of virus from infected cells and the prevention of formation of viral aggregates after release from cells. Resistance to oseltamivir has been induced in the laboratory and from post-treatment isolates from infected humans. Oseltamivir or oseltamivir carboxylate do not act as substrates or inhibitors for any CYP-450 isoenzymes.

It has been postulated that oseltamivir may limit the ability of canine parvovirus to pass through intestinal mucosa and infect intestinal crypt cells. There is evidence that oseltamivir has this effect (increased mucous inactivation) on influenza viruses in the respiratory tract of humans. Additionally, it may reduce GI bacteria colonization, translocation and toxin production.

Pharmacokinetics

No information was located for the pharmacokinetic profiles of oseltamivir in dogs, cats or horses. In humans, oseltamivir phosphate is readily absorbed and converted into the carboxylate (active) form predominantly via liver esterases. The bioavailability of oseltamivir carboxylate is about 75%; it is minimally bound to plasma proteins. Elimination of oseltamivir carboxylate is primarily via renal mechanisms, both glomerular filtration and tubular secretion. Elimination half-life is about 6–10 hours in patients with normal renal function. Up to 20% of a dose may be eliminated in the feces.

Contraindications/Precautions/Warnings

Oseltamivir should not be used in patients with documented hypersensitivity to it. For efficacy, treatment must begin as early as possible. Delay in treatment beyond 40 hours after the onset of clinical signs in humans with influenza is associated with minimal efficacy. Dosages may need adjustment in patients with severe renal insufficiency.

Studies where neonatal rats were administered 1 g/kg levels of the prodrug in the brain were 1500X greater and the active metabolite was 3 times higher than those found in adult rats. Potentially, newborn puppies could exhibit similar findings; neurotoxicity is a possibility.

In 2006, the FDA banned the extra-label use of oseltamivir and other influenza antivirals in chickens, turkeys and ducks.

Adverse Effects

Adverse effect profile in animals is not known. In the study mentioned above performed in horses, no adverse effects were noted. In humans, oseltamivir can cause gastrointestinal effects (nausea, vomiting), insomnia and vertigo. Bronchitis has been reported, but may be an artifact associated with influenza infection. Gastrointestinal effects are usually transient and may be alleviated by giving the medication with food.

Reproductive/Nursing Safety

Oseltamivir appears to be relatively safe during pregnancy. In rabbits, doses of 150 and 500 mg/kg (13X, 100X) caused dose-dependent increases of minor skeletal abnormalities. In humans, the FDA categorizes oseltamivir as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Oseltamivir and oseltamivir carboxylate have been detected in the milk of lactating rats. Safety during nursing cannot be guaranteed, but it is unlikely to pose significant risk in nursing veterinary patients.

Overdosage/Acute Toxicity

Oseltamivir has relatively low toxic potential. In humans, overdoses of up to 1000 mg have caused only nausea and vomiting.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oseltamivir and may be of significance in veterinary patients:

- **PROBENECID:** May increase 2-fold the exposure to oseltamivir carboxylate (active metabolite) by reducing tubular secretion. This could potentially be useful in reducing drug dosages or dosing frequency, or increasing serum concentrations at the usual dosage, however, supporting data is not readily available. Because of the implications associated with treating H5N1 influenza in humans, expect more information to be published on this interaction in the future. See the Probenecid monograph for more information.
- **VACCINES, INFLUENZA (live):** Oseltamivir may potentially reduce the immune response to live influenza virus vaccines. There does not appear to be any effect on inactivated (killed) vaccines.

Laboratory Considerations

No concerns noted

Doses

■ DOGS:

For adjunctive treatment of canine parvovirus enteritis:

- a) 2.2 mg/kg PO q12h. Should be administered as early as possible in the course of the disease. More data is needed to prove efficacy. (Macintire 2006f)

■ HORSES:

For treatment of equine Influenza A:

- a) 2 mg/kg PO twice daily for 5 days. Must be given early in the course of the disease to obtain satisfactory outcome. Dose used in this experimental study was based upon human pediatric dosage; not equine pharmacokinetic or pharmacodynamic data. This study also showed efficacy in reducing the clinical effects of influenza when used prophylactically. Dosage used was 2 mg/kg PO once daily for 5 days, but the authors concluded that this dosage may need to be given longer or changed for better prophylaxis. (Yamanaka, Tsujimura et al. 2006)

Monitoring

- Efficacy

Client Information

- If used in veterinary patients, clients should understand the experimental nature of using this treatment

Chemistry/Synonyms

Oseltamivir phosphate occurs as a white crystalline solid. Molecular weights are 312.4 for the free base and 410.4 for the phosphate salt.

Oseltamivir phosphate may also be known as GS-4104/002, or Ro-64-0796/002 and *Tamiflu*®.

Storage/Stability

Oseltamivir capsules should be stored at 25°C, excursions are permitted to 15–30°C. The oral powder for reconstitution should be stored between 15–30°C. Once reconstituted with 23 mL of water, it should be stored at room temperature (15–30°C) or in the refrigerator (2–8°C) and protected from freezing. After reconstitution, it is stable for 10 days.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

In 2006, the FDA banned the extra-label use of oseltamivir and other influenza antivirals in chickens, turkeys and ducks.

HUMAN-LABELED PRODUCTS:

Oseltamivir Phosphate Oral Capsules: 30, 45, & 75 mg (as base); *Tamiflu*® (Roche); (Rx)

Oseltamivir Phosphate Powder for Oral Suspension: 12 mg/mL (as base) after reconstitution in 25 mL bottles; Tutti-frutti flavor, contains sorbitol, and saccharin; *Tamiflu*® (Roche); (Rx)

OXACILLIN SODIUM

(ox-a-sill-in)

ANTI-STAPHYLOCOCCAL PENICILLIN

Prescriber Highlights

- ▶ Oral & intramammary isoxazolyl (anti-staphylococcal) penicillin
- ▶ Contraindications: Hypersensitivity to penicillins; do not use oral medications in critically ill patients
- ▶ Predominant adverse effects are GI in nature
- ▶ Must dose orally quite often (6–8h); owner compliance may be an issue

Uses/Indications

The veterinary use of these agents has been primarily in the treatment of bone, skin, and other soft tissue infections in small animals when penicillinase-producing *Staphylococcus* species have been isolated. Because of its rapid elimination and required frequent dosing, it is infrequently used.

Pharmacology/Actions

Cloxacillin, dicloxacillin and oxacillin have nearly identical spectrums of activity and can be considered therapeutically equivalent when comparing *in vitro* activity. These penicillinase-resistant penicillins have a narrower spectrum of activity than the natural penicillins. Their antimicrobial efficacy is aimed directly against penicillinase-producing strains of gram-positive cocci, particularly staphylococcal species. They are sometimes called anti-staphylococcal penicillins. There are documented strains of *Staphylococcus* that are resistant to these drugs (so-called methicillin-resistant or oxacillin-resistant Staph), but these strains have only begun to be a significant problem in veterinary species. While this class of penicillins does have activity against some other gram-positive and

gram-negative aerobes and anaerobes, other antibiotics (penicillins and otherwise) are usually better choices. The penicillinase-resistant penicillins are inactive against *Rickettsia*, mycobacteria, fungi, *Mycoplasma*, and viruses.

Pharmacokinetics

Oxacillin sodium is resistant to acid inactivation in the gut, but is only partially absorbed after oral administration. The bioavailability after oral administration in humans has been reported to range from 30–35%, and, if given with food, both the rate and extent of absorption is decreased. After IM administration, oxacillin is rapidly absorbed and peak levels generally occur within 30 minutes.

The drug is distributed to the lungs, kidneys, bone, bile, pleural fluid, synovial fluid, and ascitic fluid. The volume of distribution is reportedly 0.4 L/kg in human adults and 0.3 L/kg in dogs. As with the other penicillins, only minimal amounts are distributed into the CSF, but levels are increased with meningeal inflammation. In humans, approximately 89–94% of the drug is bound to plasma proteins.

Oxacillin is partially metabolized to both active and inactive metabolites. These metabolites and the parent compound are rapidly excreted in the urine via both glomerular filtration and tubular secretion mechanisms. A small amount of the drug is also excreted in the feces via biliary elimination. The serum half-life in humans with normal renal function ranges from about 18–48 minutes. In dogs, the elimination half-life has been reported as 20–30 minutes.

Contraindications/Precautions/Warnings

Penicillins are contraindicated in patients with a history of hypersensitivity to them. Because there may be cross-reactivity, use penicillins cautiously in patients who are documented hypersensitive to other beta-lactam antibiotics (e.g., cephalosporins, cefamycins, carbapenems).

Do not administer systemic antibiotics orally in patients with septicemia, shock, or other grave illnesses as absorption of the medication from the GI tract may be significantly delayed or diminished. Parenteral (preferably IV) routes should be used for these cases.

Adverse Effects

Adverse effects with the penicillins are usually not serious and have a relatively low frequency of occurrence.

Hypersensitivity reactions unrelated to dose can occur with these agents and can manifest as rashes, fever, eosinophilia, neutropenia, agranulocytosis, thrombocytopenia, leukopenia, anemias, lymphadenopathy, or full-blown anaphylaxis. In humans, it is estimated that 1–15% of patients hypersensitive to cephalosporins will also be hypersensitive to penicillins. The incidence of cross-reactivity in veterinary patients is unknown.

When given orally, penicillins may cause GI effects (anorexia, vomiting, diarrhea). Because the penicillins may also alter gut flora, antibiotic-associated diarrhea can occur and allow the proliferation of resistant bacteria in the colon (superinfections).

Neurotoxicity (e.g., ataxia in dogs) has been associated with very high doses or very prolonged use. Although the penicillins are not considered hepatotoxic, elevated liver enzymes have been reported. Other effects reported in dogs include tachypnea, dyspnea, edema, and tachycardia.

Reproductive/Nursing Safety

Penicillins have been shown to cross the placenta and safe use of them during pregnancy has not been firmly established, but neither have there been any documented teratogenic problems associated with these drugs; however, use only when the potential benefits outweigh the risks. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet*

demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: A (*Probably safe. Although specific studies may not have proved the safety of all drugs in dogs and cats, there are no reports of adverse effects in laboratory animals or women.*)

Penicillins are excreted in maternal milk in low concentrations; use may cause diarrhea, candidiasis, or allergic response in nursing offspring.

Overdosage/Acute Toxicity

Acute oral penicillin overdoses are unlikely to cause significant problems other than GI distress, but other effects are possible (see Adverse effects). In humans, very high dosages of parenteral penicillins, especially in patients with renal disease, have induced CNS effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxacillin and may be of significance in veterinary patients:

- **AMINOGLYCOSIDES:** *In vitro* evidence of synergism with oxacillin against *S. aureus* strains
- **CYCLOSPORINE:** Oxacillin may reduce levels
- **PROBENECID:** Competitively blocks the tubular secretion of oxacillin, thereby increasing serum levels and serum half-lives
- **TETRACYCLINES:** Theoretical antagonism; use together usually not recommended
- **WARFARIN:** Oxacillin may cause decreased warfarin efficacy

Laboratory Considerations

- As penicillins and other beta-lactams can inactivate aminoglycosides *in vitro* (and *in vivo* in patients in renal failure), serum concentrations of **aminoglycosides** may be falsely decreased if the patient is also receiving beta-lactam antibiotics and the serum is stored prior to analysis. It is recommended that if the assay is delayed, samples be frozen and, if possible, drawn at times when the beta-lactam antibiotic is at a trough.

Doses

Note: Oxacillin is only available commercially in the USA for use as a parenteral injection and an oral suspension. For oral therapy, dicloxacillin capsules may be substituted for oxacillin.

- **DOGS:**
 - For susceptible infections:
 - a) 22–40 mg/kg PO, SC, IM, or IV q8h (Lappin 2003a)
 - b) For non-superficial pyoderma: 25–30 mg/kg PO three times daily for 3–6 weeks. Maximum dose is 1 gram three times daily. Increase dose if no response in one week. If no response by second week, discontinue. (Aucoin 2002a)
 - c) For Staph. acute osteomyelitis: 22 mg/kg IV, IM, SC or PO three to four times daily (Harari 2003)
 - d) For penicillinase-producing Staph. Endocarditis: 50–60 mg/kg three times daily for 4–6 weeks (route not indicated) (Sisson and Thomas 1986)
 - e) For systemic therapy for Staph. blepharitis: 22 mg/kg PO three times daily (Laratta 1986)

■ CATS:

For susceptible infections:

- a) 22–40 mg/kg PO, SC, IM, or IV q8h (Lappin 2003a)

■ HORSES:

For susceptible infections:

- a) Foals: 20–30 mg/kg IV q6–8h (Dose extrapolated from adult horse data; use lower dose or longer interval in premature foals or those less than 7 days old.) (Caprile and Short 1987); (Brumbaugh 1999)
- b) 25–50 mg/kg IM, IV twice daily (Robinson 1987)

Monitoring

- Because penicillins usually have minimal toxicity associated with their use, monitoring for efficacy is usually all that is required unless toxic signs develop. Serum levels and therapeutic drug monitoring are not routinely done with these agents.

Client Information

- Unless otherwise instructed by the veterinarian, this drug should be given to an animal with an empty stomach, at least 1 hour before feeding or 2 hours after.
- Keep oral solution in the refrigerator and discard any unused suspension after 14 days.

Chemistry/Synonyms

An isoxazolyl-penicillin, oxacillin sodium is a semi-synthetic penicillinase-resistant penicillin. It is available commercially as the monohydrate sodium salt, which occurs as a fine, white, crystalline powder that is odorless or has a slight odor. It is freely soluble in water and has a pK_a of about 2.8. One mg of oxacillin sodium contains not less than 815–950 micrograms of oxacillin. Each gram of the commercially available powder for injection contains 2.8–3.1 mEq of sodium.

Oxacillin sodium may also be known as: sodium oxacillin, methylphenyl isoxazolyl penicillin (5-methyl-3-phenyl-4-isoxazolyl) penicillin sodium, oxacillinum natricum, oxacillinum natrium, P-12, or SQ-16423.

Storage/Stability/Compatibility

Oxacillin sodium powder for oral solution, and powder for injection should be stored at room temperature (15–30°C) in tight containers. After reconstituting with water, refrigerate and discard any remaining oral solution after 14 days. If kept at room temperature, the oral solution is stable for 3 days.

After reconstituting the sterile powder for injection with sterile water for injection or sterile sodium chloride 0.9%, the resultant solution with a concentration of 167 mg/mL is stable for 3 days at room temperature or 7 days if refrigerated. The manufacturer recommends using different quantities of diluent depending on whether the drug is to be administered IM, IV directly, or IV (piggyback). Refer to the package insert for specific instructions.

Oxacillin sodium injection is reportedly physically **compatible** with the following fluids/drugs: dextrose 5% and 10% in water, dextrose 5% and 10% in sodium chloride 0.9%, lactated Ringer's injection, sodium chloride 0.9% amikacin sulfate, cephapirin sodium, chloramphenicol sodium succinate, dopamine HCl, potassium chloride, sodium bicarbonate, and verapamil.

Oxacillin sodium injection is reportedly physically **incompatible** with the following fluids/drugs: oxytetracycline HCl and tetracycline HCl. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Oxacillin Sodium Powder for Oral Solution: 250 mg/5 mL when reconstituted in 100 mL; generic; (Rx)

Oxacillin Sodium Powder for Injection: 500 mg, 1 g & 2 g in vials, *Add-Vantage* vials, and piggyback vials; 10 g bulk vials; generic; (Rx)

OXAZEPAM

(ox-a-ze-pam) Serax®

BENZODIAZEPINE

Prescriber Highlights

- ▶ Benzodiazepine used primarily as an appetite stimulant in cats, but may also be useful to treat behavior problems in dogs or cats
- ▶ Contraindications: Known benzodiazepine hypersensitivity, acute narrow angle glaucoma. Caution: Myasthenia gravis, hepatic dysfunction, seizure disorders.
- ▶ Adverse Effects: Primarily sedation & occasionally, ataxia.
- ▶ Possibly teratogenic
- ▶ C-IV Controlled substance

Uses/Indications

Oxazepam is used most frequently in small animal medicine as an appetite stimulant in cats and dogs. It may also be useful as an oral anxiolytic agent for adjunctive therapy of behavior-related disorders for both dogs and cats.

Pharmacology/Actions

The subcortical levels (primarily limbic, thalamic, and hypothalamic) of the CNS are depressed by oxazepam and other benzodiazepines thus producing the anxiolytic, sedative, skeletal muscle relaxant and anticonvulsant effects seen. The exact mechanism of action is unknown, but postulated mechanisms include: antagonism of serotonin, increased release of gamma-aminobutyric acid (GABA) and/or facilitation of GABA activity, and diminished release or turnover of acetylcholine in the CNS. Benzodiazepine specific receptors have been located in the mammalian brain, kidney, liver, lung, and heart. In all species studied, receptors are lacking in the white matter.

Pharmacokinetics

Oxazepam is absorbed from the GI tract, but it is one of the more slowly absorbed oral benzodiazepines. Oxazepam, like other benzodiazepines is widely distributed; it is highly bound to plasma proteins (97% in humans). While not confirmed, oxazepam may cross the placenta and enter maternal milk. Oxazepam is principally conjugated in the liver via glucuronidation to an inactive metabolite. Serum half-life in humans ranges from 3–21 hours.

Contraindications/Precautions/Warnings

Oxazepam is contraindicated in patients who are hypersensitive to it or other benzodiazepines or have acute narrow angle glaucoma. Benzodiazepines have been reported to exacerbate myasthenia gravis. While oxazepam is less susceptible to accumulation than many other benzodiazepines in patients with hepatic dysfunction, it should be used with caution nonetheless.

Adverse Effects

The most prevalent adverse effects seen with oxazepam in small animals is sedation and occasionally, ataxia. These may be transient and dosage adjustment may be required to alleviate. Paradoxical effects such as excitability, vocalization or aggression are possible. When used to treat negative behaviors, a rebound effect can occur, particularly if the drug is not withdrawn slowly.

Rarely, oxazepam has reportedly precipitated tonic-clonic seizures; use with caution in susceptible patients. Potentially, oxazepam could cause hepatic toxicity in cats, but this occurs very rarely.

Reproductive/Nursing Safety

Safe use during pregnancy has not been established; teratogenic effects of similar benzodiazepines have been noted in rabbits and rats. In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*)

Benzodiazepines are excreted in maternal milk. Since neonates metabolize benzodiazepines more slowly than adults do, accumulation of the drug and its metabolites to toxic levels is possible. Chronic diazepam use in nursing mothers reportedly caused human infants to be lethargic and lose weight; avoid the use of benzodiazepines in nursing patients.

Overdosage/Acute Toxicity

When used alone, oxazepam overdoses are generally limited to significant CNS depression (confusion, coma, decreased reflexes, etc.). Treatment of significant overdoses consists of standard protocols for removing and/or binding the drug (if taken orally) in the gut, and supportive systemic measures. The use of analeptic agents, (CNS stimulants such as caffeine, amphetamines, etc.) are generally not recommended. Flumazenil could potentially be used in life-threatening overdoses.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxazepam and may be of significance in veterinary patients:

- **CNS DEPRESSANT DRUGS:** If oxazepam administered with other CNS depressant agents (**barbiturates, narcotics, anesthetics**, etc.) additive effects may occur
- **PHENYTOIN:** May decrease oxazepam concentrations
- **PROBENECID:** May impair glucuronide conjugation (in dogs) and prolong effects
- **RIFAMPIN:** May induce hepatic microsomal enzymes and decrease the pharmacologic effects of benzodiazepines
- **ST. JOHN'S WORT:** May decrease oxazepam effectiveness
- **THEOPHYLLINES:** May decrease oxazepam effectiveness

Laboratory Considerations

- Benzodiazepines may decrease the thyroidal uptake of I^{123} or I^{131} .

Doses

■ DOGS:

For treating fears and phobias:

- a) 0.2–0.5 mg/kg PO q12–24h (Siebert 2003c)
- b) 0.2–1 mg/kg PO q12–24h (Virga 2002)
- c) 0.2–1 mg/kg one to two times a day (Landsberg 2005b)

■ CATS:

As an appetite stimulant:

- a) 2 mg per cat (total dose) every 12 hours (Hartke, Rojko et al. 1992), (Hodgkins and Franks 1991)

- b) In cats with hepatic lipidosis, if cat has a small interest in eating: 0.1–0.3 mg/kg PO q12–24h (Twedt 2005c)
 - c) 0.25–0.5 mg/kg PO one to two times daily. (Sparkes 2005)
- For behavior-related conditions:
- a) For treating fears and phobias: 1–2.5 mg per cat (total dose) PO every 12 hours (Siebert 2003c)
 - b) For treating fears and phobias 0.2–0.5 mg/kg PO q12–24h (Virga 2002)
 - c) For feline urine marking: 0.2–0.5 mg/kg PO once to twice a day. (Landsberg 2007)
 - d) For spraying or overgrooming: 0.2–0.5 mg/kg PO q12–24h (Seksell 2006)

Monitoring

- Efficacy
- Adverse effects

Client Information

- Caution clients not to discontinue medication or adjust dosage without first checking with veterinarian.
- Efficacy for anorexia may be improved if given just prior to feeding as effects are generally seen within 30 minutes.

Chemistry/Synonyms

A benzodiazepine, oxazepam occurs as a creamy white to pale yellow powder. It is practically insoluble in water.

Oxazepam may also be known as: oxazepamum, Wy-3498, and *Serax*®.

Storage/Stability/Compatibility

Store oxazepam capsules and tablets at room temperature in well-closed containers.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Oxazepam Capsules: 10 mg, 15 mg & 30 mg; *Serax*® (Alpharma); generic; (Rx; C-IV)

Oxazepam Tablets: 15 mg; *Serax*® (Alpharma); (Rx; C-IV)

OXFENDAZOLE

(ox-fen-da-zole) *Synanthic*®

ANTIPARASITIC AGENT (ANTHELMINTIC)

Prescriber Highlights

- ▶ Benzimidazole anthelmintic used primarily in cattle
- ▶ Contraindications: Not for use in female dairy cattle of breeding age
- ▶ Caution: Debilitated or sick horses; 7 day slaughter withdrawal in cattle
- ▶ Adverse Effects: Unlikely; hypersensitivity possible

Uses/Indications

Oxfendazole (*Synanthic*®) is indicated in cattle for the removal and control of lungworms, roundworms (including inhibited forms of *Ostertagia ostertagi*) and tapeworms.

Oxfendazole as *Benzelmin*® was indicated (no longer marketed in the USA) for the removal of the following parasites in horses: large roundworms (*Parascaris equorum*), large strongyles (*S. edentatus*, *S. equinus*, *S. vulgaris*), small strongyles, and pinworms (*Oxyuris equi*).

Oxfendazole has also been used extra-label in sheep, goats, and swine; see Dosage section for more information.

Pharmacology/Actions

Benzimidazole antiparasitic agents have a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, their mechanism of action is believed due to disrupting intracellular microtubular transport systems by binding selectively and damaging tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles also act at higher concentrations to disrupt metabolic pathways within the helminth, and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase.

Pharmacokinetics

Limited information is available regarding this compound's pharmacokinetics. Unlike most of the other benzimidazole compounds, oxfendazole is absorbed more readily from the GI tract. The elimination half-life has been reported to be about 7.5 hours in sheep and 5.25 hours in goats. Absorbed oxfendazole is metabolized (and vice-versa) to the active compound, fenbendazole (sulfoxide) and the sulfone.

Contraindications/Precautions/Warnings

Not for use in female dairy cattle of breeding age. A 7 day slaughter withdrawal is required when using at labeled doses.

There are no contraindications to using this drug in horses, but it is recommended to use oxfendazole cautiously in debilitated or sick horses.

Adverse Effects

When used as labeled, it is unlikely any adverse effects will be noted. Hypersensitivity reactions secondary to antigen release by dying parasites are theoretically possible, particularly at high dosages.

Reproductive/Nursing Safety

Oxfendazole may be safely used in pregnant mares and foals.

Overdosage/Acute Toxicity

Doses of 10 times those recommended elicited no adverse reactions in horses tested. It is unlikely that this compound would cause serious toxicity when given alone.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxfendazole and may be of significance in veterinary patients:

- **BROMSALAN FLUKICIDES** (*dibromsalan*, *tribromsalan*): Oxfendazole should not be given concurrently with these agents; abortions in cattle and death in sheep have been reported after using these compounds together

Doses

■ DOGS:

- a) For *Oslerus osleri*: 10 mg/kg PO once daily for 28 days. (Bowman 2006a)

■ HORSES:

- a) For susceptible parasites: 10 mg/kg PO (Roberson 1988b), (Package insert; *Benzelmin*®—Fort Dodge)

■ CATTLE:

- a) For susceptible parasites: 4.5 mg/kg either PO or via intraruminal injection (22.5% only). May repeat in 4–6 weeks. Dose of the 9.06% suspension is 2.5 mL per 100 lb (50 kg) of body weight PO. Dose of the 22.5% suspension is 1 mL per 100 lb (50 kg) of body weight either PO or intraruminal injection. See package label for specific directions if giving by intraruminal injection. (Package inserts; *Synanthic*® 9.06% and 22.5%—Fort Dodge)

■ SWINE:

- a) For susceptible parasites: 3–4.5 mg/kg PO (Roberson 1988b)

■ SHEEP:

- a) For susceptible parasites: 5 mg/kg PO (Roberson 1988b), (Brander, Pugh, and Bywater 1982)

■ GOATS:

- a) For susceptible parasites: 7.5 mg/kg PO (Roberson 1988b)

Monitoring

- Efficacy

Client Information

- Not to be used in horses intended for food purposes
- Shake suspension well
- Slaughter withdrawal in cattle is 7 days; not approved for lactating dairy cattle

Chemistry/Synonyms

A benzimidazole anthelmintic, oxfendazole occurs as white or almost white powder possessing a characteristic odor. It is practically insoluble in water. Oxfendazole is the sulfoxide metabolite of fenbendazole.

Oxfendazole may also be known as RS 8858; there are many international trade names.

Storage/Stability

Unless otherwise directed by the manufacturer, oxfendazole products should be stored at room temperature and protected from light. The manufacturer recommends discarding any unused suspension 24 hours after it has been reconstituted.

Dosage Forms/Preparations/Regulatory Status

VETERINARY-LABELED PRODUCTS:

Oxfendazole Oral Suspension: 9.06% in 1 liter and 4 liter. *Synanthic*® (Fort Dodge); (OTC). Approved for use in beef cattle and in female dairy cattle not of breeding age. At recommended dosages, slaughter withdrawal is 7 days.

Oxfendazole Oral Suspension: 22.5% in 500 mL and 1 liter. *Synanthic*® (Fort Dodge); (Rx). Approved for use in beef cattle and in female dairy cattle not of breeding age. At recommended dosages, slaughter withdrawal is 7 days.

HUMAN-LABELED PRODUCTS: None

OXIBENDAZOLE

(ox-i-ben-da-zole) Anthelcide EQ®

ANTIPARASITIC AGENT (ANTHELMINTIC)

Prescriber Highlights

- Benzimidazole anthelmintic used primarily in horses
- **Contraindications:** Severely debilitated horses or in horses suffering from colic, toxemia or infectious disease.
- **Adverse Effects:** Unlikely; hypersensitivity possible

Uses/Indications

Oxibendazole is indicated (labeled) for the removal of the following parasites in horses: large roundworms (*Parascaris equorum*), large strongyles (*S. edentatus*, *S. equinus*, *S. vulgaris*), small strongyles, threadworms, and pinworms (*Oxyuris equi*).

Oxibendazole has also been used in cattle, sheep, and swine; see Dosage section for more information.

Pharmacology/Actions

Benzimidazole antiparasitic agents have a broad spectrum of activity against a variety of pathogenic internal parasites. In susceptible parasites, their mechanism of action is believed due to disrupting intracellular microtubular transport systems by binding selectively and damaging tubulin, preventing tubulin polymerization, and inhibiting microtubule formation. Benzimidazoles also act at higher concentrations to disrupt metabolic pathways within the helminth, and inhibit metabolic enzymes, including malate dehydrogenase and fumarate reductase.

Pharmacokinetics

No information was located.

Contraindications/Precautions/Warnings

Oxibendazole is stated by the manufacturer to be contraindicated in severely debilitated horses or in horses suffering from colic, toxemia, or infectious disease.

Adverse Effects

When used in horses at recommended doses, it is unlikely any adverse effects would be seen. Hypersensitivity reactions secondary to antigen release by dying parasites are theoretically possible, particularly at high dosages.

Oxibendazole in combination with diethylcarbamazine (*Filaribits Plus*®) was implicated in causing periportal hepatitis in dogs when it was marketed (1980's).

Reproductive/Nursing Safety

Oxibendazole is considered safe to use in pregnant mares.

Overdosage/Acute Toxicity

Doses of 60 times those recommended elicited no adverse reactions in horses tested. It is unlikely that this compound would cause serious toxicity when given alone to horses.

Drug Interactions

No significant interactions have been reported

Doses**■ HORSES:**

For susceptible parasites:

- a) 10 mg/kg PO; 15 mg/kg PO for strongyloides; horses maintained on premises where reinfection is likely to occur should be retreated in 6–8 weeks. (Package insert; *Anthelcide EQ*®—Pfizer)
- b) 10 mg/kg, PO (Robinson 1987), (Roberson 1988b)

■ CATTLE:

For susceptible parasites:

- a) 10–20 mg/kg PO (Brander, Pugh, and Bywater 1982)

■ SWINE:

For susceptible parasites:

- a) 15 mg/kg, PO (Roberson 1988b)

■ SHEEP:

For susceptible parasites:

- a) 10–20 mg/kg PO (Brander, Pugh, and Bywater 1982)

Monitoring

- Efficacy

Client Information

- Protect suspension from freezing
- Shake suspension well before using
- Not for use in horses intended for food

Chemistry/Synonyms

A benzimidazole anthelmintic, oxibendazole occurs as a white powder that is practically insoluble in water.

Oxibendazole may also be known as SKF-30310 and *Anthelcide EQ*® and in the U.K. by the proprietary names: *Dio*® (Alan Hitchings), *Equidin*® (Univet), *Equitac*® (SKF) or *Loditac*® (SKF).

Storage/Stability

Unless otherwise directed by the manufacturer, oxibendazole products should be stored at room temperature; protect from freezing.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Oxibendazole Suspension: 100 mg/mL (10%) in gallons. *Anthelcide EQ*® Suspension (Pfizer); (Rx). Approved for use in horses not used for food.

Oxibendazole Oral Paste: 227 mg/gram (22.7%) in 24-gram syringes. *Anthelcide EQ*® Paste (Pfizer); (OTC). Approved for use in horses not used for food.

HUMAN-LABELED PRODUCTS: None**OXYBUTYNIN CHLORIDE**

(ox-i-byoo-tin-in) Ditropan®, Oxytrol®

GENITOURINARY SMOOTH MUSCLE RELAXANT**Prescriber Highlights**

- Urinary antispasmodic potentially useful in dogs or cats
- Cautions (risk vs. benefit): Obstructive GI tract disease or intestinal atony/paralytic ileus, angle closure glaucoma, hiatal hernia, cardiac disease (particularly associated with mitral stenosis, associated arrhythmias, tachycardia, CHF, etc.), myasthenia gravis, hyperthyroidism, prostatic hypertrophy, severe ulcerative colitis, urinary retention, or other obstructive uropathies
- Adverse Effects: Diarrhea, constipation, urinary retention, hypersalivation, & sedation

Uses/Indications

Oxybutynin may be useful for the adjunctive therapy of detrusor hyperreflexia in dogs and in cats with FeLV-associated detrusor instability.

Pharmacology/Actions

Considered a urinary antispasmodic, oxybutynin has direct antimuscarinic (atropine-like) and spasmolytic (papaverine-like) effects on smooth muscle. Spasmolytic effects appear to be most predominant on the detrusor muscle of the bladder and small and large intestine. It does not have appreciable effects on vascular smooth muscle. Studies done in patients with neurogenic bladders showed that oxybutynin increased bladder capacity, reduced the frequency of uninhibited contractions of the detrusor muscle and delayed initial desire to void. Effects were more pronounced in patients with uninhibited neurogenic bladders than in patients with reflex neurogenic bladders. Other effects noted in lab animal studies include moderate antihistaminic, local anesthetic, mild analgesic, very low mydriatic, and antisialagogue effects.

Pharmacokinetics

Oxybutynin is apparently rapidly and well absorbed from the GI tract. Studies done in rats show the drug distributed into the brain, lungs, kidneys, and liver. While elimination characteristics have not been well documented, oxybutynin apparently is metabolized in the liver and excreted in the urine. In humans, the duration of action is from 6–10 hours after a dose.

Contraindications/Precautions/Warnings

Because of the drug's pharmacologic actions, oxybutynin should be used when its benefits outweigh its risks if the following conditions are present: obstructive GI tract disease or intestinal atony/paralytic ileus, angle closure glaucoma, hiatal hernia, cardiac disease (particularly associated with mitral stenosis, associated arrhythmias, tachycardia, CHF, etc.), myasthenia gravis, hyperthyroidism, prostatic hypertrophy, severe ulcerative colitis, urinary retention or other obstructive uropathies.

Adverse Effects

While use in small animals is limited, diarrhea, constipation, urinary retention, hypersalivation, and sedation have been reported. Other adverse effects reported in humans, and potentially seen in animals, primarily result from the drug's pharmacologic effects, including: dry mouth or eyes, tachycardia, anorexia, vomiting, weakness, or mydriasis.

Reproductive/Nursing Safety

While safety during pregnancy has not been firmly established, studies in a variety of lab animals have demonstrated no teratogenic effect associated with the drug. In humans, the FDA categorizes this drug as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

It is not known whether this drug is excreted in maternal milk. While oxybutynin may inhibit lactation, no documented problems associated with its use in nursing offspring have been noted.

Overdosage/Acute Toxicity

Overdosage may cause CNS effects (e.g., restlessness, excitement, seizures), cardiovascular effects (e.g., hyper- or hypotension, tachycardia, circulatory failure), fever, nausea or vomiting. Massive overdoses may lead to paralysis, coma, respiratory failure and death. Treatment of overdoses should consist of general techniques to limit absorption of the drug from the GI tract and supportive care as required; intravenous physostigmine may be useful. See the atropine monograph for more information on the use of physostigmine.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxybutynin and may be of significance in veterinary patients:

- **ANTICHOLINERGIC AGENTS** (e.g., atropine, propantheline, scopolamine, isopropamide, glycopyrrolate, hyoscyamine, tricyclic antidepressants, disopyramide, procainamide, antihistamines, etc.): May intensify oxybutynin's anticholinergic effects
- **AZOLE ANTIFUNGALS** (ketoconazole, etc.): May increase oxybutynin levels
- **CNS DEPRESSANTS**: Other sedating drugs may exacerbate the sedating effects of oxybutynin
- **MACROLIDE ANTIBIOTICS** (erythromycin, clarithromycin): May increase oxybutynin levels

Doses

DOGS:

To decrease bladder contractility (detrusor hyperreflexia):

- a) 0.2 mg/kg PO q8–12h; most dogs are dosed at 1.25–3.75 mg (total dose) q12h. Juvenile animals may require a prolonged dosing interval. (Lane 2000)
- b) 1.25–5 mg (total dose) PO q8–12h (Bartges 2003a)
- c) 2–5 mg (total dose) PO q8–12h (Vernau 2006)

CATS:

To decrease bladder contractility (detrusor hyperreflexia):

- a) 0.5–1 mg (total dose) PO q8–12h. Juvenile animals may require a prolonged dosing interval. (Lane 2000)
- b) 0.5–1.25 mg per cat PO q8–12h (Osborne, Kruger et al. 2000), (Bartges 2003a), (Polzin 2005c)

Monitoring

- Efficacy
- Adverse effects

Chemistry/Synonyms

A synthetic tertiary amine, oxybutynin chloride occurs as white to off-white crystals. It is freely soluble in water.

Oxybutynin chloride may also be known as: oxybutynin HCl, 5058, MJ-4309-1, oxybutynini hydrochloridum, *Ditropan*® and *Oxytrol*®.

Storage/Stability

Tablets and oral solution should be stored at room temperature in tight containers. Protect oral solution from light. Tablets have an expiration date of 4 years after manufacture.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Oxybutynin Chloride Tablets: 5 mg; *Ditropan*® (ALZA); (Rx); generic; (Rx)

Oxybutynin Chloride Extended release tablets: 5 mg, 10 mg and 15 mg; *Ditropan*® XL (ALZA); (Rx)

Oxybutynin Chloride Syrup: 1 mg/mL in 473 mL; *Ditropan*® (ALZA); (Rx)

Oxybutynin Chloride Transdermal System: 36 mg of oxybutynin delivering 3.9 mg oxybutynin per day in 39 cm² system; *Oxytrol*® (Watson); (Rx)

OXYMORPHONE HCL

(ox-ee-mor-fone) Numorphan®

OPIATE AGONIST

Prescriber Highlights

- Injectable opiate sedative/restraining agent, analgesic, & preanesthetic
- Contraindications: Hypersensitivity to it, diarrhea caused by a toxic ingestion. Extreme Caution: Respiratory disease or acute respiratory dysfunction. Caution: Hypothyroidism, severe renal insufficiency (acute uremia), adrenocortical insufficiency, geriatric or severely debilitated patients, head injuries or increased intracranial pressure & acute abdominal conditions (e.g., colic).
- Adverse Effects: Respiratory depression & bradycardia. Decreased GI motility with resultant constipation possible. Cats (high dosages): ataxia, hyperesthesia, & behavioral changes (without concomitant tranquilization)
- Availability & expense are issues
- C-II controlled substance

Uses/Indications

Oxymorphone is used in dogs and cats as a sedative/restraining agent, analgesic, and preanesthetic; occasionally in horses as an analgesic and anesthesia induction agent. It may also be used in swine as an adjunctive analgesic with ketamine/xylazine anesthesia and small rodents as an analgesic/anesthetic for minor surgical procedures.

Pharmacology/Actions

Receptors for opiate analgesics are found in high concentrations in the limbic system, spinal cord, thalamus, hypothalamus, striatum, and midbrain. They are also found in tissues such as the gastrointestinal tract, urinary tract, and other smooth muscle.

The morphine-like agonists (morphine, meperidine, oxymorphone) have primary activity at the *mu* receptors, with some activity possible at the *delta* receptor. The primary pharmacologic effects of these agents include: analgesia, antitussive activity, respiratory depression, sedation, emesis, physical dependence, and intestinal

effects (constipation/defecation). Secondary pharmacologic effects include: *CNS*: euphoria, sedation, and confusion. *Cardiovascular*: bradycardia due to central vagal stimulation, alpha-adrenergic receptors may be depressed resulting in peripheral vasodilation, decreased peripheral resistance, and baroreceptor inhibition. Orthostatic hypotension and syncope may occur. *Urinary*: Increased bladder sphincter tone can induce urinary retention.

Various species may exhibit contradictory effects from these agents. For example, horses, cattle, swine, and cats may develop excitement after morphine injections and dogs may defecate after morphine. These effects are in contrast to the expected effects of sedation and constipation. Dogs and humans may develop miosis, while other species (especially cats) may develop mydriasis. For more information, see the individual monographs for each agent.

Oxymorphone is approximately 10 times more potent an analgesic on a per weight basis when compared to morphine. It has less antitussive activity than morphine. In humans, it has more of a tendency to cause increased nausea and vomiting than does morphine, while in dogs the opposite appears to be true. At the usual doses employed, oxymorphone alone has good sedative qualities in the dog. Respiratory depression can occur especially in debilitated, neonatal or geriatric patients. Bradycardia, as well as a slight decrease in cardiac contractility and blood pressure, may also be seen. Like morphine, oxymorphone does initially increase the respiratory rate (panting in dogs) while actual oxygenation may be decreased and blood CO₂ levels may increase by 10 mmHg or more. Oxymorphone may cause more panting in dogs than morphine. Gut motility is decreased with resultant increases in stomach emptying times. Unlike either morphine or meperidine, oxymorphone does not appear to cause histamine release when administered IV and may cause less excitement than morphine.

Pharmacokinetics

Oxymorphone is absorbed when given by IV, IM, SC, and rectal routes. Although absorbed when given orally, bioavailability is reduced, probably from a high first-pass effect. After IV administration, analgesic efficacy usually occurs within 3–5 minutes.

Like morphine, oxymorphone concentrates in the kidney, liver, and lungs; lower levels are found in the CNS. Oxymorphone crosses the placenta and narcotized newborns can result if mothers are given the drug before giving birth, but these effects can be rapidly reversed with naloxone.

The drug is metabolized in the liver; primarily by glucuronidation. Because cats are deficient in this metabolic pathway, half-lives in cats are probably prolonged. The kidneys excrete the glucuronidated metabolite.

Contraindications/Precautions/Warnings

All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), and in geriatric or severely debilitated patients. Oxymorphone is contraindicated in patients hypersensitive to narcotic analgesics, those receiving monamine oxidase inhibitors (MAOIs), or with diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract.

Oxymorphone should be used with extreme caution in patients with head injuries, increased intracranial pressure or acute abdominal conditions (e.g., colic) as it may obscure the diagnosis or clinical course of these conditions, and suffering from respiratory disease or from acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation).

Oxymorphone can cause bradycardia and, therefore, should be used cautiously in patients with preexisting bradyarrhythmias.

Neonatal, debilitated, or geriatric patients may be more susceptible to the effects of oxymorphone and may require lower dosages. Patients with severe hepatic disease may have prolonged duration of action of the drug. If used in cats at high dosages, it is recommended the drug be given along with a tranquilizing agent as oxymorphone can produce bizarre behavioral changes in this species. This also is true in cats for the other opiate agents, such as morphine.

Opiate analgesics are also contraindicated in patients who have been stung by the scorpion species *Centruroides sculpturatus* Ewing and *C. gertschi* Stahnke as it may potentiate these venoms.

Adverse Effects

Oxymorphone may cause respiratory depression and bradycardia (see above). When used in cats at high dosages, oxymorphone may cause ataxia, hyperesthesia, and behavioral changes (without concomitant tranquilization). Decreased GI motility with resultant constipation has been described.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category *C* for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: *B* (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

Most opioids appear in maternal milk, but effects on offspring may not be significant. Withdrawal symptoms have occurred in breastfeeding human infants when maternal administration of an opioid-analgesic is stopped.

Overdosage/Acute Toxicity

Massive overdoses may produce profound respiratory and/or CNS depression in most species. Other effects may include cardiovascular collapse, hypothermia, and skeletal muscle hypotonia. Naloxone is the agent of choice in treating respiratory depression. In massive overdoses, naloxone doses may need to be repeated, and animals should be closely observed as naloxone's effects sometimes diminish before sub-toxic levels of oxymorphone are attained. Mechanical respiratory support should be considered in cases of severe respiratory depression.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxymorphone and may be of significance in veterinary patients:

- **BUTORPHANOL, NALBUPHINE**: Potentially could antagonize opiate effects
- **CNS DEPRESSANTS, OTHER**: Additive CNS effects possible
- **DIURETICS**: Opiates may decrease efficacy in CHF patients
- **MONOAMINE OXIDASE INHIBITORS** (e.g., amitraz, possibly selegiline): Use MAOI's with oxymorphone with extreme caution as meperidine (a related opiate) is contraindicated in human patients receiving monamine oxidase (MAO) inhibitors for at least 14 days after receiving MAO inhibitors. Some human patients have exhibited signs of opiate overdose after receiving therapeutic doses of meperidine while taking MAOIs.
- **MUSCLE RELAXANTS, SKELETAL**: Oxymorphone may enhance effects
- **PHENOTHIAZINES**: Some phenothiazines may antagonize analgesic effects and increase risk for hypotension

- **TRICYCLIC ANTIDEPRESSANTS** (clomipramine, amitriptyline, etc.): Oxymorphone may exacerbate the effects of tricyclic antidepressants
- **WARFARIN:** Opiates may potentiate anticoagulant activity

Laboratory Considerations

- As they may increase biliary tract pressure, opiates can increase plasma **amylase** and **lipase** values up to 24 hours following their administration.

Doses

■ DOGS:

For sedation for minor procedures:

- a) Up to 0.2 mg/kg IM or IV; initially a maximum of 5 mg total dose (Combine with acepromazine 0.05–0.1 mg/kg IM or IV) (Shaw et al. 1986)
- b) 0.05–0.1 mg/kg IV or 0.1–0.2 mg/kg IM, SC (Morgan 1988)

For analgesia (acute pain):

- a) 0.1–0.2 mg/kg IM, IV, or SC q1–3h (Hendrix and Hansen 2000)
- b) For animals with cardiovascular disease: 0.05–0.1 mg/kg IV, IM or SC q2–4h (Hansen 2003a)
- c) Epidural administration: 0.05 mg/kg. Dilution may be necessary for accurate measurement. Total volume administered is not to exceed 0.3 mL/kg. (Mathews 1999)
- d) 0.1–0.2 mg/kg IM or SC q3–4h for acute pain. (Gaynor 2007)
- e) 0.05–0.4 mg/kg IV, IM, or SC q2–4h (Wagner 2002)

For premedication to anesthesia in healthy dogs:

- a) 0.1–0.2 mg/kg IM or IV (used with acepromazine and atropine or glycopyrrolate unless contraindicated. Thiopental/thiamylal dose may be reduced to 2–4 mg/kg when using high end of oxymorphone dose). (Shaw et al. 1986)

Induction of anesthesia in geriatric or sick dogs:

- a) 0.1–0.2 mg/kg IM or IV; give incrementally to effect (administered alternately with diazepam at 0.2–0.5 mg/kg; use with atropine or glycopyrrolate unless contraindicated; follow with halothane, methoxyflurane or isoflurane) (Shaw et al. 1986)

Facilitation of inhalation anesthesia without thiobarbiturates or ketamine in sight hounds:

- a) Up to 0.2 mg/kg IV or IM (Combine with acepromazine; use with atropine or glycopyrrolate unless contraindicated) (Shaw et al. 1986)

■ CATS:

For restraint/sedation for minor procedures:

- a) 0.05 mg/kg IV, SC or IM; may cause dysphoria in cats without pain or with excessive dose (Carroll 1999)
- b) 0.025–0.1 mg/kg IV (must be given with tranquilizer; e.g., acepromazine 0.1 mg/kg) (Shaw et al. 1986)
- c) 0.02–0.03 mg/kg IV or IM with or without another tranquilizer (Mandsager 1988)

As a preanesthetic/analgesic:

- a) 0.1–0.4 mg/kg IV (Shaw et al. 1986)

As an analgesic (acute pain):

- a) 0.05–0.1 mg/kg IM, SC or IV q1–3h; concomitant tranquilization recommended (Hendrix and Hansen 2000)
- b) For animals with cardiovascular disease: 0.05–0.1 mg/kg IV, IM or SC q2–4h (Hansen 2003a)
- c) 0.025–0.1 mg/kg IV (IM or SC) q2–6h (Scherk 2003a)
- d) 0.02–0.1 mg/kg IV, IM, or SC q3–4h (Wagner 2002)

■ FERRETS:

- a) 0.05–0.2 mg/kg IV or IM 2–4 times daily (Williams 2000)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 0.2 mg/kg IM q2–4h (Ivey and Morrissey 2000)
- b) Anesthetic/analgesic for minor surgical procedures: 0.15 mg/kg IM (for a hamster-sized animal) (Shaw et al. 1986)
- c) Hamsters, Gerbils, Mice, Rats, Guinea pigs: 0.2–0.5 mg/kg SC, IM q6–12h for analgesia (Adamcak and Otten 2000)

■ HORSES: (Note: ARCI UCGFS Class 1 Drug)

As an analgesic:

- a) 0.01–0.02 mg/kg IV (Muir 1987)
- b) 0.01–0.022 mg/kg IV; up to 15 mg total (divide dose into 3–4 increments and give several minutes apart) (Shaw et al. 1986)
- c) 0.02–0.03 mg/kg IM (Robinson 1987)
- d) 0.015–0.03 mg/kg IV (Thurmon and Benson 1987)

Anesthetic induction in severely compromised horses:

- a) 0.01–0.022 mg/kg IV (after approx. 45 minutes, may be necessary to “top off” with another 1/3 of the original dose) (Shaw et al. 1986)

Note: Narcotics (oxymorphone included) may cause CNS excitement in the horse. Some clinicians recommend pretreatment with acepromazine (0.02–0.04 mg/kg IV), or xylazine (0.3–0.5 mg/kg IV) to reduce the behavioral changes these drugs can cause.

Warning: Narcotic analgesics can mask the behavioral and cardiovascular clinical signs associated with mild colic.

■ SWINE:

- a) To increase analgesia when used with ketamine (2 mg/kg)/xylazine (2 mg/kg): 0.075 mg/kg IV (duration of anesthesia and recumbency: 20–30 minutes) (Shaw et al. 1986)

Monitoring

- Respiratory rate/depth
- CNS level of depression/excitation
- Blood pressure (especially with IV use)
- Analgesic activity
- Cardiac rate

Client Information

- When given parenterally, this agent should be used in an inpatient setting or with direct professional supervision.

Chemistry/Synonyms

A semi-synthetic phenanthrene narcotic agonist, oxymorphone HCl occurs as odorless white crystals or white to off-white powder. It will darken in color with prolonged exposure to light. One gram of oxymorphone HCl is soluble in 4 mL of water; it is sparingly soluble in alcohol or ether. The commercially available injection has a pH of 2.7–4.5.

Oxymorphone HCl may also be known as: 7,8-Dihydro-14-hydroxymorphinone hydrochloride, or oximorphone hydrochloride, *Numorphan*® and *Opana*®.

Storage/Stability/Compatibility

The injection should be stored protected from light and at room temperature (15–30°C); avoid freezing. The commercially available suppositories should be stored at temperatures between 2–15°C. Oxymorphone has been reported to be physically **compatible** when mixed with acepromazine, atropine, and glycopyrrolate. It is physically **incompatible** when mixed with barbiturates or diazepam.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:** None

The ARCI (Racing Commissioners International) has designated this drug as a class 1 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Oxymorphone HCl Tablets: 5 mg & 10 mg; *Opana*® (Endo Pharmaceuticals); (Rx, C-II)

Oxymorphone HCl Extended-Release Tablets: 5 mg, 10 mg, 20 mg & 40 mg; *Opana*® ER (Endo Pharmaceuticals); (Rx, C-II)

Oxymorphone HCl for Injection: 1 mg/mL in 1 mL amps; *Nunomorph*® (Endo Laboratories); (Rx, C-II)

Note: Oxymorphone is a Class-II controlled substance. Very accurate record keeping is required as to use and disposition of stock.

OXYTETRACYCLINE OXYTETRACYCLINE HCL

(ox-it-tet-ra-sye-kleen) Terramycin®

TETRACYCLINE ANTIBIOTIC

Prescriber Highlights

- ▶ Tetracycline antibiotic; while many bacteria are now resistant, it still may be very useful to treat mycoplasma, rickettsia, spirochetes, & Chlamydia
- ▶ Contraindications: Hypersensitivity. Extreme Caution: Pregnancy. Caution: Liver, renal insufficiency
- ▶ Adverse Effects: GI distress, staining of developing teeth & bones, superinfections, photosensitivity; long-term use may cause uroliths. CATS do not tolerate very well. HORSES: if stressed may break with diarrheas (oral use). RUMINANTS: high oral doses can cause ruminal microflora depression & ruminoreticular stasis. Rapid IV of undiluted propylene glycol-based products can cause intravascular hemolysis & cardiodepressant effects. IM: local reactions, yellow staining & necrosis may be seen at the injection site.

Uses/Indications

Oxytetracycline products are approved for use in dogs and cats (no known products are being marketed, however), calves, non-lactating dairy cattle, beef cattle, swine, fish, and poultry. For more information, refer to the Doses section, below.

Pharmacology/Actions

Tetracyclines generally act as bacteriostatic antibiotics and inhibit protein synthesis by reversibly binding to 30S ribosomal subunits of susceptible organisms, preventing binding to those ribosomes of aminoacyl transfer-RNA. Tetracyclines also are believed to reversibly bind to 50S ribosomes and additionally alter cytoplasmic membrane permeability in susceptible organisms. In high concentrations, tetracyclines can also inhibit protein synthesis by mammalian cells.

As a class, the tetracyclines have activity against most mycoplasma, spirochetes (including the Lyme disease organism), Chlamydia, and Rickettsia. Against gram-positive bacteria, the tetracyclines have activity against some strains of staphylococci and streptococci, but resistance of these organisms is increasing. Gram-positive bac-

teria that are usually covered by tetracyclines, include *Actinomyces* spp., *Bacillus anthracis*, *Clostridium perfringens* and *tetani*, *Listeria monocytogenes*, and *Nocardia*. Among gram-negative bacteria that tetracyclines usually have *in vitro* and *in vivo* activity include *Bordetella* spp., *Brucella*, *Bartonella*, *Haemophilus* spp., *Pasturella multocida*, *Shigella*, and *Yersinia pestis*. Many or most strains of *E. coli*, *Klebsiella*, *Bacteroides*, *Enterobacter*, *Proteus* and *Pseudomonas aeruginosa* are resistant to the tetracyclines. While most strains of *Pseudomonas aeruginosa* show *in vitro* resistance to tetracyclines, those compounds attaining high urine levels (e.g., tetracycline, oxytetracycline) have been associated with clinical cures in dogs with UTI secondary to this organism.

Oxytetracycline and tetracycline share nearly identical spectrums of activity and patterns of cross-resistance. A tetracycline susceptibility disk is usually used for *in vitro* testing for oxytetracycline susceptibility.

Pharmacokinetics

Both oxytetracycline and tetracycline are readily absorbed after oral administration to fasting animals. Bioavailabilities are approximately 60–80%. The presence of food or dairy products can significantly reduce the amount of tetracycline absorbed, with reductions of 50% or more possible. After IM administration of oxytetracycline (not long-acting), peak levels may occur in 30 minutes to several hours, depending on the volume and site of injection. The long-acting product (*LA-200*®) has significantly slower absorption after IM injection.

Tetracyclines as a class are widely distributed in the body, including to the heart, kidney, lungs, muscle, pleural fluid, bronchial secretions, sputum, bile, saliva, urine, synovial fluid, ascitic fluid, and aqueous and vitreous humor. Only small quantities of tetracycline and oxytetracycline are distributed to the CSF and therapeutic levels may not be attainable. While all tetracyclines distribute to the prostate and eye, doxycycline or minocycline penetrate better into these and most other tissues. Tetracyclines cross the placenta, enter fetal circulation and are distributed into milk. The volume of distribution of oxytetracycline is approximately 2.1 L/kg in small animals, 1.4 L/kg in horses, and 0.8 L/kg in cattle. The amount of plasma protein binding is about 10–40% for oxytetracycline.

Both oxytetracycline and tetracycline are eliminated unchanged primarily via glomerular filtration. Patients with impaired renal function can have prolonged elimination half-lives and may accumulate the drug with repeated dosing. These drugs apparently are not metabolized, but are excreted into the GI tract via both biliary and nonbiliary routes and may become inactive after chelation with fecal materials. The elimination half-life of oxytetracycline is approximately 4–6 hours in dogs and cats, 4.3–9.7 hours in cattle, 10.5 hours in horses, 6.7 hours in swine, and 3.6 hours in sheep.

Contraindications/Precautions/Warnings

Oxytetracycline is contraindicated in patients hypersensitive to it or other tetracyclines. Because tetracyclines can retard fetal skeletal development and discolor deciduous teeth, they should only be used in the last half of pregnancy when the benefits outweigh the fetal risks. Oxytetracycline and tetracycline are considered more likely to cause these abnormalities than either doxycycline or minocycline.

In patients with renal insufficiency or hepatic impairment, oxytetracycline and tetracycline must be used cautiously. Lower than normal dosages are recommended with enhanced monitoring of renal and hepatic function. Avoid concurrent administration of other nephrotoxic or hepatotoxic drugs with tetracyclines. Monitoring of serum levels should be considered if long-term therapy is required.

Adverse Effects

Oxytetracycline and tetracycline given to young animals can cause a yellow, brown, or gray discoloration of bones and teeth. High dosages or chronic administration may delay bone growth and healing.

Tetracyclines in high levels can exert an antianabolic effect, which can cause an increase in BUN and/or hepatotoxicity, particularly in patients with preexisting renal dysfunction. As renal function deteriorates secondary to drug accumulation, this effect may be exacerbated.

In ruminants, high oral doses can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria. Propylene glycol based products have also caused cardiodepressant effects when administered to calves. When administered IM, local reactions, yellow staining, and necrosis may be seen at the injection site.

In small animals, tetracyclines can cause nausea, vomiting, anorexia, and diarrhea. Cats do not tolerate oral tetracycline or oxytetracycline very well, and may present with clinical signs of colic, fever, hair loss, and depression. There are reports that long-term tetracycline use may cause urolith formation in dogs.

Horses, who are stressed by surgery, anesthesia, trauma, etc., may break with severe diarrheas after receiving tetracyclines (especially with oral administration).

Tetracycline therapy (especially long-term) may result in overgrowth (superinfections) of non-susceptible bacteria or fungi.

Tetracyclines have also been associated with photosensitivity reactions and, rarely, hepatotoxicity or blood dyscrasias.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **D** for use during pregnancy (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **D** (*Contraindicated. These drugs have been shown to cause congenital malformations or embryotoxicity.*)

Tetracyclines are excreted in maternal milk. Milk to plasma ratios varies between 0.25 to 1.5. Because of the potential for serious adverse reactions, decide whether to discontinue nursing or discontinue the drug.

Overdosage/Acute Toxicity

Tetracyclines are generally well tolerated after acute overdoses. Dogs given more than 400 mg/kg/day orally or 100 mg/kg/day IM of oxytetracycline did not demonstrate any toxicity. Oral overdoses would most likely be associated with GI disturbances (vomiting, anorexia, and/or diarrhea). Should the patient develop severe emesis or diarrhea, fluids and electrolytes should be monitored and replaced if necessary. Chronic overdoses may lead to drug accumulation and nephrotoxicity.

High oral doses given to ruminants, can cause ruminal microflora depression and ruminoreticular stasis. Rapid intravenous injection of undiluted propylene glycol-based products can cause intravascular hemolysis with resultant hemoglobinuria.

Rapid intravenous injection of tetracyclines has induced transient collapse and cardiac arrhythmias in several species, presumably due to chelation with intravascular calcium ions. Overdose quantities of drug could exacerbate this effect if given too rapidly IV. If the drug must be given rapidly IV (less than 5 minutes), some clinicians recommend pre-treating the animal with intravenous calcium gluconate.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxytetracycline and may be of significance in veterinary patients:

- **ATOVAQUONE:** Tetracyclines have caused decreased atovaquone levels
- **BETA-LACTAM or AMINOGLYCOSIDE ANTIBIOTICS:** Bacteriostatic drugs, like the tetracyclines, may interfere with bactericidal activity of the penicillins, cephalosporins, and aminoglycosides; there is some controversy regarding the actual clinical significance of this interaction, however.
- **DIGOXIN:** Tetracyclines may increase the bioavailability of digoxin in a small percentage of human patients and lead to digoxin toxicity. These effects may persist for months after discontinuation of the tetracycline.
- **DIVALENT OR TRIVALENT CATIONS (oral antacids, saline cathartics or other GI products containing aluminum, calcium, iron, magnesium, zinc, or bismuth cations):** When orally administered, tetracyclines can chelate divalent or trivalent cations that can decrease the absorption of the tetracycline or the other drug if it contains these cations; it is recommended that all oral tetracyclines be given at least 1–2 hours before or after the cation-containing products.
- **METHOXYFLURANE:** Fatal nephrotoxicity has occurred in humans when used with tetracycline; concomitant use with oxytetracycline is not recommended
- **WARFARIN:** Tetracyclines may depress plasma prothrombin activity and patients on anticoagulant therapy may need dosage adjustment

Laboratory Considerations

- Tetracyclines (not minocycline) may cause falsely elevated values of **urine catecholamines** when using fluorometric methods of determination.
- Tetracyclines reportedly can cause false-positive **urine glucose** results if using the cupric sulfate method of determination (Benedict's reagent, *Clinitest*®), but this may be the result of ascorbic acid, which is found in some parenteral formulations of tetracyclines. Tetracyclines have also reportedly caused false-negative results in determining urine glucose when using the glucose oxidase method (*Clinistix*®, *Tes-Tape*®).

Doses

■ DOGS:

For susceptible infections:

- a) For systemic infections: 22 mg/kg PO q8h for 7–14 days or 20 mg/kg IM (using repositol form) every 7 days as needed. (Greene, Hartmann et al. 2006)
- b) 20 mg/kg PO q8–12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden and Papich 1995)

■ CATS:

For susceptible infections:

- a) For hemotropic mycoplasmosis: 10–25 mg/kg PO, IV q8h for 5–7 days (Greene, Hartmann et al. 2006)
- b) 20 mg/kg PO q8–12h; (may give with food if GI upset occurs; avoid or reduce dose in animals with renal or severe liver failure; avoid in young, pregnant or breeding animals) (Vaden and Papich 1995)
- c) For haemobartonellosis: 16–20 mg/kg PO three times daily for 3 weeks (Lissman 1988)

■ **RABBITS, RODENTS, SMALL MAMMALS:**

- a) Rabbits: 15 mg/kg SC, IM q8h; 15–50 mg/kg PO once daily; 1 mg/mL in drinking water (Ivey and Morrissey 2000)
- b) Chinchillas: 50 mg/kg PO q12h (Hayes 2000); (Adamcak and Otten 2000)
- c) Gerbils: 10 mg/kg PO q8h or 20 mg/kg SC q24h; Guinea Pigs: 50 mg/kg, PO q12h; Hamsters: 16 mg/kg, SC q24h; Mice: 10–20 mg/kg PO q8h; Rats: 10–20 mg/kg PO q8h or 6–10 mg/kg IM q12h (Adamcak and Otten 2000)

■ **CATTLE:**

For susceptible infections:

- a) 5–10 mg/kg IM q24h or 20 mg/kg q48–72h IM if depot form (*LA*[®]-200); 2.5–5 mg/kg, IV q24h; 10–20 mg/kg, PO q12h (Jenkins 1986)
- b) For respiratory tract infections: Using 50 mg/mL product: 11 mg/kg IM or SC q24h or IV q12–24h; Using 100 mg/mL, product: 20 mg/kg IM q24h; Using 200 mg/mL, product (*LA*-200[®]): 20 mg/kg IM q3–4 days; IM or SC doses should be injected into the neck and not more than 10 mL per site. IM route may lead to myositis and abscesses. Rapid IV injection may cause collapse. Phlebitis is possible with IV dosing. (Beech 1987b)
- c) For anthrax: 4.4 mg/kg IM or IV daily. Do not use in healthy animals recently vaccinated against anthrax as the protective effect of the vaccine may be negated. (Kaufmann 1986)
- d) For bovine anaplasmosis:

For control: At start of vector season give 6.6–11 mg/kg (if using 50 mg/mL or 100 mg/mL product) or 20 mg/kg (if using depot form —*LA*[®]-200) every 21–28 days and extending 1–2 months after vector season ends.

To eliminate carrier state: If using 50 mg/mL or 100 mg/mL product: 22 mg/kg IM (not over 10 mL per injection site) or IV (diluted in saline) daily for 5 days; or 11 mg/kg as above for 10 days. If using depot form (*LA*[®]-200): Give 20 mg/kg for 4 treatments deep IM in two separate injection sites at 3-day intervals.

For treatment of sick animals: Preferably using depot form (*LA*[®]-200): Give 20 mg/kg one time.

For temporary/prolonged protection for rest of herd: If using 50 mg/mL or 100 mg/mL product: 6.6–11 mg/kg IM (not over 10 mL per injection site) repeat at 21–28 day intervals throughout vector season for prolonged protection. If using depot form (*LA*[®]-200): Give 20 mg/kg IM as above and repeat at 28-day intervals for prolonged protection. (Richey 1986)

- e) For pneumonia: If using 50 mg/mL or 100 mg/mL product: 11 mg/kg SC once daily. If using depot form (*LA*[®]-200): Give 20 mg/kg IM q48h (Hjerpe 1986)

■ **HORSES:**

For susceptible infections:

- a) Foals: 5–10 mg/kg IV q12h diluted and given slowly, or 10–20 mg/kg IV q24h diluted and given slowly. Monitor creatinine and UA. (Bentz 2007)
- b) Drug of choice for equine monocytic or granulocytic ehrlichiosis: 6.6 mg/kg IV q24h; to safeguard against adverse effects (muscle tremors, agitation or acute collapse) dilute at least in a 1:1 ratio and give IV slowly, or deliver it as an infusion in 500 mL or 1 liter of fluids. (Bentz 2007)
- c) For Lyme disease: 6.6 mg/kg IV once to twice daily (Divers 1999)

- d) For Potomac Horse Fever (*Ehrlichia risticii*) early in the clinical course of the disease: 6.6 mg/kg IV twice a day. Usually no more than 5 days treatment is necessary.

For Equine Granulocytic Ehrlichiosis: 7 mg/kg once daily for 5–7 days (Madigan and Pusterla 2000)

- e) For intrauterine infusion: 1–5 grams; use povidone based products only. Little science is available for recommending doses, volume infused, frequency, diluents, etc. Most intrauterine treatments are commonly performed every day or every other day for 3–7 days. (Perkins 1999)

■ **SWINE:**

For susceptible infections:

- a) For anthrax: 4.4 mg/kg IM or IV daily. Do not use in healthy animals recently vaccinated against anthrax as the protective effect of the vaccine may be negated. (Kaufmann 1986)
- b) 6–11 mg/kg IV or IM; 10–20 mg/kg PO q6h (Howard 1986)
- c) If using 50 mg/mL or 100 mg/mL product: 10 mg/kg IM initially, then 7.5 mg/kg IM once daily (Baggot 1983)

■ **SHEEP & GOATS:**

For susceptible infections:

- a) For anthrax: 4.4 mg/kg IM or IV daily. Do not use in healthy animals recently vaccinated against anthrax as the protective effect of the vaccine may be negated. (Kaufmann 1986)
- b) 6–11 mg/kg IV or IM; 10–20 mg/kg PO q6h (Howard 1986)

■ **BIRDS:**

For chlamydiosis (Psittacosis):

- a) Using 200 mg/mL product (*LA*-200[®]): 50 mg/kg IM once every 3–5 days in birds suspected or confirmed of having disease. Used in conjunction with other forms of tetracyclines. IM injections may cause severe local tissue reactions. (McDonald 1989)
- b) Using 200 mg/mL, product (*LA*-200[®]): 200 mg/kg IM once daily for 3–5 days. Has worked well in treating breeding birds to control outbreak and while getting birds to eat oral forms doxycycline or chlortetracycline. (Clubb 1986)

■ **REPTILES:**

For susceptible infections:

- a) For turtles and tortoises: 10 mg/kg PO once daily for 7 days (useful in ulcerative stomatitis caused by *Vibrio*) (Gauvin 1993)

Monitoring

- Adverse effects
- Clinical efficacy
- Long-term use or in susceptible patients: periodic renal, hepatic, hematologic evaluations

Client Information

- Avoid giving this drug orally within 1–2 hours of feeding, milk, or other dairy products

Chemistry/Synonyms

A tetracycline derivative obtained from *Streptomyces rimosus*, oxytetracycline base occurs as a pale yellow to tan, crystalline powder that is very slightly soluble in water and sparingly soluble in alcohol. Oxytetracycline HCl occurs as a bitter-tasting, hygroscopic, yellow, crystalline powder that is freely soluble in water and sparingly soluble in alcohol. Commercially available 50 mg/mL and 100 mg/mL oxytetracycline HCl injections are usually available in either propylene glycol or povidone-based products.

Oxytetracycline may also be known as: glomycin, hydroxytetracycline, oxytetracyclinum, riomitsin, terrafungine, *Biomycin*®, *Liquamycin*®, *Medamycin*®, *Oxyject*®, *Oxytet*®, and *Terramycin*®.

Storage/Stability/Compatibility

Unless otherwise directed by the manufacturer, oxytetracycline HCl and oxytetracycline products should be stored in tight, light-resistant containers at temperatures of less than 40°C (104°F) and preferably at room temperature (15–30°C); avoid freezing.

Oxytetracycline HCl is generally considered to be physically **compatible** with most commonly used IV infusion solutions, including D₅W, sodium chloride 0.9%, and lactated Ringer's, but can become relatively unstable in solutions with a pH >6, particularly in those containing calcium. This is apparently more of a problem with the veterinary injections that are propylene glycol based, rather than those that are povidone based. Other drugs that are reported to be physically **compatible** with oxytetracycline for injection include: colistimethate sodium, corticotropin, dimenhydrinate, insulin (regular), isoproterenol HCl, methyldopate HCl, norepinephrine bitartrate, polymyxin B sulfate, potassium chloride, tetracycline HCl, and vitamin B-complex with C.

Drugs that are reportedly physically **incompatible** with oxytetracycline, data conflicts, or compatibility is concentration/time dependent, include: amikacin sulfate, aminophylline, amphotericin B, calcium chloride/gluconate, carbenicillin disodium, cephalothin sodium, cephapirin sodium, chloramphenicol sodium succinate, erythromycin gluceptate, heparin sodium, hydrocortisone sodium succinate, iron dextran, methicillin sodium, methohexital sodium, oxacillin sodium, penicillin G potassium/sodium, pentobarbital sodium, phenobarbital sodium, and sodium bicarbonate. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status/Withdrawal Times

VETERINARY-LABELED PRODUCTS:

Oxytetracycline HCl 50 mg/mL, 100 mg/mL Injection: There are many approved oxytetracycline products marketed in these concentrations. Some trade names for these products include: *Terramycin*®, *Liquamycin*®, *Biomycin*® (Bio-Ceutic), *Medamycin*® (TechAmerica), *Biocyl*® (Anthony), *Oxyject*® (Fermenta), and *Oxytet*® (BI). Some are labeled for Rx (prescription) use only, while some are over-the-counter (OTC). Depending on the actual product, this drug may be approved for use in swine, cattle, beef cattle, chickens or turkeys. Products may also be labeled for IV, IM, or SC use. Withdrawal times vary with regard to individual products; when used as labeled, slaughter withdrawal times vary in cattle from 15–22 days, swine 20–26 days, and 5 days for chickens and turkeys. Refer to the actual labeled information for the product used for more information.

Oxytetracycline base 200 mg/mL Injection in 100, 250, and 500 mL bottles; *Liquamycin*® LA-200 (Pfizer); (OTC or Rx). Approved for use in swine and cattle. When used as labeled, slaughter withdrawal = 28 days for swine and cattle; Milk withdrawal = 96 hours

Oxytetracycline Oral Tablets (Boluses) 250 mg tablet; *Terramycin*® *Scours Tablets* (Pfizer); (OTC). Approved for use in non-lactating dairy and beef cattle. Slaughter withdrawal (at labeled doses) = 7 days.

Oxytetracycline is also available in feed additive, premix, ophthalmic, and intramammary products.

Established residue tolerances: Uncooked edible tissues of swine, cattle, salmonids, catfish and lobsters: 0.10 ppm. Uncooked kidneys of chickens or turkeys: 3 ppm. Uncooked muscle, liver, fat or skin of chickens or turkeys: 1 ppm.

HUMAN-LABELED PRODUCTS:

Oxytetracycline For Injection: 50 mg/mL or 125 mg/mL (both with 2% lidocaine) in 2 mL amps and 10 mL multidose vials (125 mg/mL only); *Terramycin*® (Roerig/Pfizer); (Rx)

OXYTOCIN

(ox-i-toe-sin) Pitocin®

HORMONAL AGENT

Prescriber Highlights

- Hypothalamic hormone used for induction or enhancement of uterine contractions at parturition, postpartum retained placenta & metritis, uterine involution after manual correction of prolapsed uterus in dogs, & agalactia.
- Contraindications: Known hypersensitivity, dystocia due to abnormal presentation of fetus(es) unless correction is made. When used prepartum, oxytocin should be used only when the cervix is relaxed naturally or by the prior administration of estrogens.
- Treat hypoglycemia or hypocalcemia before using
- Adverse Effects: Usually occur only when used in inappropriate patients or at too high a dosage.
- Drug Interactions

Uses/Indications

In veterinary medicine, oxytocin has been used for induction or enhancement of uterine contractions at parturition, treatment of postpartum retained placenta and metritis, uterine involution after manual correction of prolapsed uterus in dogs, and in treating agalactia.

Pharmacology/Actions

By increasing the sodium permeability of uterine myofibrils, oxytocin stimulates uterine contraction. The threshold for oxytocin-induced uterine contraction is reduced with pregnancy duration, in the presence of high estrogen levels and in patients already in labor.

Oxytocin can facilitate milk ejection, but does not have any galactopoietic properties. While oxytocin only has minimal antidiuretic properties, water intoxication can occur if it is administered at too rapid a rate and/or if excessively large volumes of electrolyte-free intravenous fluids are administered.

Pharmacokinetics

Oxytocin is destroyed in the GI tract and, therefore, must be administered parenterally. After IV administration, uterine response occurs almost immediately. Following IM administration, the uterus responds generally within 3–5 minutes. The duration of effect in dogs after IV or IM/SC administration has been reported to be 13 minutes and 20 minutes, respectively. While oxytocin can be administered intranasally, absorption can be erratic. Oxytocin is distributed throughout the extracellular fluid. It is believed that small quantities of the drug cross the placenta and enter the fetal circulation.

In humans, plasma half-life of oxytocin is about 3–5 minutes. In goats, this value has been reported to be about 22 minutes. Oxytocin is metabolized rapidly in the liver and kidneys and a circulating enzyme, oxytocinase can also destroy the hormone. Very small amounts of oxytocin are excreted in the urine unchanged.

Contraindications/Precautions/Warnings

Oxytocin is considered contraindicated in animals with dystocia due to abnormal presentation of fetus(es), unless correction is made. When used prepartum, oxytocin should be used only when the cervix is relaxed naturally or by the prior administration of estrogens (**Note:** Most clinicians avoid the use of estrogens, as natural relaxation is a better indicator for the proper time to induce contractions.) Oxytocin is also contraindicated in patients who are hypersensitive to it.

Before using oxytocin, treat hypoglycemia or hypocalcemia if present.

In humans, oxytocin is contraindicated in patients with significant cephalopelvic disproportion, unfavorable fetal positions, in obstetrical emergencies when surgical intervention is warranted, severe toxemia, or when vaginal delivery is contraindicated. Nasally administered oxytocin is contraindicated in pregnancy.

Adverse Effects

When used appropriately at reasonable dosages, oxytocin rarely causes significant adverse reactions. Most adverse effects are a result of using the drug in inappropriate individuals (adequate physical exam and monitoring of patient are essential) or at too high doses (see Overdosage below). Most of the older dosage recommendations for dogs or cats are obsolete as mini doses have been found to improve the frequency of uterine contractility, and are less hazardous to the bitch (uterine rupture) and to the fetuses (placental compromise). Hypersensitivity reactions are a possibility in non-synthetically produced products. Repeated bolus injections of oxytocin may cause uterine cramping and discomfort.

Overdosage/Acute Toxicity

Effects of overdosage on the uterus depend on the stage of the uterus and the position of the fetus(es). Hypertonic or tetanic contractions can occur leading to tumultuous labor, uterine rupture, fetal injury, or death.

Water intoxication can occur if large doses are infused for a long period, especially if large volumes of electrolyte-free intravenous fluids are concomitantly being administered. Early clinical signs can include listlessness or depression. More severe intoxication clinical signs can include coma, seizures and eventually death. Treatment for mild water intoxication is stopping oxytocin therapy and restricting water access until resolved. Severe intoxication may require the use of osmotic diuretics (mannitol, urea, dextrose) with or without furosemide.

Reproductive/Nursing Safety

In humans, oxytocin is contraindicated in patients with significant cephalopelvic disproportion, unfavorable fetal positions, in obstetrical emergencies when surgical intervention is warranted, severe toxemia, or when vaginal delivery is contraindicated. Nasally administered oxytocin is contraindicated in pregnancy.

No known indications for use in the first trimester exist other than in relation to spontaneous or induced abortion. Oxytocin is not expected to present a risk of fetal abnormalities when use as indicated.

Oxytocin may be found in small quantities in maternal milk but is unlikely to have significant effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving oxytocin and may be of significance in veterinary patients:

- **THIOPENTAL:** One case in humans has been reported where thiopental anesthesia was delayed when oxytocin was being administered. The clinical significance of this interaction has not been firmly established.
- **VASOCONSTRICTORS:** If sympathomimetic agents or other vasoconstrictors are used concurrently with oxytocin post-partum hypertension may result. Monitor and treat if necessary.

Doses

■ DOGS:

To augment uterine contractions during parturition:

- a) 0.5–3 Units SC or IM every 30–60 minutes, best based upon the results of tokodynamometry. (Davidson 2004b)

For uterine inertia if no fetuses in birth canal, cervix is dilated, and fetal and maternal obstruction have been ruled out:

- a) Oxytocin at 5–20 Units (depending on size of animal) IM or as an IV drip (10 Units/liter) beginning as a slow drip and gradually increasing until effective contractions are observed. If no response to IM injection in 30 minutes, may repeat along with 10% dextrose IV slowly. If no response again in 30 minutes, repeat IM again. Some texts recommend giving calcium gluconate (2–10 mL slowly IV while monitoring ECG for bradycardia or arrhythmias). If no response to this medical management, perform Caesarian section. (Macintire 2006e)

To induce milk let-down in bitches with adequate milk production and who tolerate nursing:

- a) Oxytocin nasal spray (*Syntocinon*®): 5–10 minutes prior to nursing three times daily (Loar 1988)

For adjunctive treatment of acute metritis:

- a) To promote uterine involution and evacuation: 0.5–1 Unit/kg IM; may repeat in 1–2 hours. It's less effective if parturition occurred several days ago. (Magne 1986)

To promote uterine involution after uterine prolapse manual reduction:

- a) 5–20 Units IM (Nelson 1988)

■ CATS:

To promote uterine involution after uterine prolapse manual reduction:

- a) 5 Units IM once (Morgan 1988)

To treat primary uterine inertia:

- a) 0.25–1 unit SC or IM every 30–60 minutes, best based upon the results of tokodynamometry (Davidson 2004b)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Mice, Rats, Gerbils, Hamsters, Guinea pigs, Chinchillas: 0.2–3 IU/kg IV, IM or SC (Adamcak and Otten 2000)

■ CATTLE:

For retained placenta in patients

- a) 40–60 Units oxytocin q2h (often used in conjunction with intravenous calcium therapy) as necessary. Of limited value after 48 hours postpartum as uterine sensitivity is reduced. (McClary 1986)
- b) To reduce incidence of retained placenta: 20 Units IM immediately following calving and repeated 2–4 hours later (Hameida, Gustafsson, and Whitmore 1986)

For mild to moderate cases of acute post-partum metritis:

- a) 20 Units IM 3–4 times a day for 2–3 days (Hameida, Gustafsson, and Whitmore 1986)

To augment uterine contractions during parturition:

- a) 30 Units IM; repeat no sooner than 30 minutes if necessary (Wheaton 1989)
- b) For obstetrical use in cows: 100 Units IV, IM or SC (Package Insert; Oxytocin Injection—Anthony Products)

For milk let-down in cows:

- a) 10–20 Units IV (Package Insert; Oxytocin Injection—Anthony Products)

■ HORSES:

To augment or initiate uterine contractions during parturition in properly evaluated mares:

- a) For induction: 2.5–5 IU IV, every 15–20 minutes until foal is born (McCue 2003a)

For evacuation of uterine fluid:

- a) 20 IU IV or IM one to three times a day (McCue 2003a)

To aid in removal of retained fetal membranes:

- a) Oxytocin: 30–100 Units in 1 liter of normal saline IV over 30–60 minutes *or* 10–120 IU IM *or* 10–40 IU by IV bolus (**Note:** large dose IV boluses are not recommended as they may cause uterine spasm and abdominal discomfort) (Perkins 1999)

- b) Oxytocin: 20 IU IV or IM given every hour beginning 2–3 hours after foaling. Repeat as needed. (McCue 2003a)

For mild to moderate cases of acute post-partum metritis:

- a) 20 Units IM 3–4 times a day for 2–3 days (Hameida, Gustafsson, and Whitmore 1986)

■ SWINE:

For adjunctive treatment of agalactia syndrome (MMA) in sows:

- a) 30–40 Units per sow at 3–4 hours (Powe 1986)
- b) 20–50 Units IM or 5–10 Units IV (Einarsson 1986)

For retained placenta in patients with uterine atony:

- a) 20–30 Units oxytocin q2–3h as necessary (with broad-spectrum antibiotics) (McClary 1986)

To augment uterine contractions during parturition:

- a) 10 Units IM; repeat no sooner than 30 minutes if necessary (Wheaton 1989)
- b) For obstetrical use in sows: 30–50 Units IV, IM or SC (Package Insert; Oxytocin Injection—Anthony Products)

For mild to moderate cases of acute post-partum metritis:

- a) 5–10 Units IM 3–4 times a day for 2–3 days (Hameida, Gustafsson, and Whitmore 1986)
- b) 5 Units IM; may need to be repeated as effect may be as short as 30 minutes (Meredith 1986)

For milk let-down in sows:

- a) 5–20 Units IV (Package Insert; Oxytocin Injection—Anthony Products)

■ SHEEP & GOATS:

For retained placenta in patients with uterine atony:

- a) 10–20 Units oxytocin. Of limited value after 48 hours post-partum as uterine sensitivity is reduced. If signs of metritis develop, treat with antibiotics. (McClary 1986)

For mild to moderate cases of acute post-partum metritis:

- a) 5–10 Units IM 3–4 times a day for 2–3 days (Hameida, Gustafsson, and Whitmore 1986)

To control post-extraction cervical and uterine bleeding after internal manipulations (e.g., fetotomy, etc.):

- a) Goats: 10–20 Units IV, may repeat SC in 2 hours (Franklin 1986a)

■ BIRDS:

As a uterotonic agent:

- a) 0.5 IU/kg IM; may repeat in 60 minutes (Pollock 2007b)

For egg expulsion:

- a) 0.01–0.1 mL once IM. Should be administered with Vitamin A and calcium (injectable) (Clubb 1986)

■ REPTILES:

For egg binding in combination with calcium (Calcium glubionate:

- a) Calcium glubionate (10–50 mg/kg IM as needed until calcium levels back to normal or egg binding is resolved); oxytocin: 1–10 IU/kg IM. Use care when giving multiple injections. Not as effective in lizards as in other species. (Gauvin 1993)

To induce oviposition:

- a) Doses range from 1–30 IU/kg. A dose of 10 IU/kg appears to be effective in many chelonians. May have to repeat in several hours, but there is a risk of oviduct rupture if cloaca is obstructed or eggs cannot pass for other reasons. (Lewbart 2001)

Monitoring

- Uterine contractions, status of cervix
- Fetal monitoring if available and indicated

Client Information

- Oxytocin should only be used by individuals able to adequately monitor its effects.

Chemistry/Synonyms

A nonapeptide hypothalamic hormone stored in the posterior pituitary (in mammals), oxytocin occurs as a white powder that is soluble in water. The commercially available preparations are highly purified and have virtually no antidiuretic or vasopressor activity when administered at usual doses. Oxytocin potency is standardized according to its vasopressor activity in chickens and is expressed in USP Posterior Pituitary Units. One unit is equivalent of approximately 2–2.2 micrograms of pure hormone.

Commercial preparations of oxytocin injection have their pH adjusted with acetic acid to 2.5–4.5 and multi-dose vials generally contain chlorobutanol 0.5% as a preservative.

Oxytocin may also be known as: alpha-hypophamine, or oxytocinum and *Pitocin*®.

Storage/Stability/Compatibility

Oxytocin injection should be stored at temperatures of less than 25°C, but should not be frozen. Some manufacturers recommend storing the product under refrigeration (2–8°C), but some products have been demonstrated to be stable for up to 5 years if stored at less than 26°C.

Oxytocin is reportedly physically **compatible** with most commonly used intravenous fluids and the following drugs: chloramphenicol sodium succinate, metaraminol bitartrate, netilmicin sulfate, sodium bicarbonate, tetracycline HCl, thiopental sodium, and verapamil HCl.

Oxytocin is reportedly physically **incompatible** with the following drugs: fibrinolysin, norepinephrine bitartrate, prochlorperazine edisylate, and warfarin sodium. Compatibility is dependent upon factors such as pH, concentration, temperature, and diluent used; consult specialized references or a hospital pharmacist for more specific information.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Oxytocin for Injection: 20 USP Units/mL in 10 mL, 30 mL, and 100 mL vials; available labeled generically from several manufacturers; (Rx). Oxytocin products are labeled for several species, including horses, dairy cattle, beef cattle, sheep, swine, cats, and dogs. There are no milk or meat withdrawal times specified for oxytocin.

HUMAN-LABELED PRODUCTS:

Oxytocin for Injection: 10 Units/mL in 1 mL amps, 3 mL and 10 mL vials; 1 mL Steri-Dose syringes and 1 mL Steri-Vials; Pitocin® (Monarch); generic; (Rx)

PAMIDRONATE DISODIUM

(pah-mih-dro-nate) Aredia®

BISPHOSPHONATE**Prescriber Highlights**

- ▶ Bisphosphonate used IV for treating hypercalcemia associated with Vitamin D-analog toxicity or hypercalcemia of malignancy; being investigated for adjuvant treatment of osteosarcomas
- ▶ Must be given IV in saline over several hours
- ▶ Potentially can cause electrolyte abnormalities, anemias, or renal toxicity
- ▶ Expense may be an issue

Uses/Indications

Pamidronate may be useful in treating hypercalcemia associated with vitamin D-related toxicoses or hypercalcemia of malignancy. There is ongoing research on the use of this drug to determine if it has clinical usefulness in directly treating “micro-metastases” in osteosarcomas.

Pharmacology/Actions

Bisphosphonates at therapeutic levels inhibit bone resorption and do not inhibit bone mineralization via binding to hydroxyapatite crystals. They impede osteoclast activity, and induce osteoclast apoptosis. Pamidronate has approximately 100 times greater relative antiresorptive potency when compared to etidronate.

Bisphosphonates *in vitro* have direct cytotoxic or cytostatic effects on human osteosarcoma cell lines. They may also have antiangiogenic effects and inhibit cell migration in certain cancers.

Pharmacokinetics

After intravenous infusion in rats, 50–60% of the dose is rapidly absorbed by bone. Bone uptake is highest in areas of rapid bone turnover. The kidneys very slowly eliminate the drug. Terminal half-life is on the order of 300 days in rats.

Contraindications/Precautions/Warnings

Pamidronate is contraindicated in patients hypersensitive to it or any of the bisphosphonate drugs. It should be used with caution in patients with impaired renal function; the drug has been associated with renal toxicity. In humans, it has not been tested in patients with serum creatinine levels greater than 5 mg/dL.

Adverse Effects

Electrolyte abnormalities may occur with pamidronate therapy. One case of a dog developing hypomagnesemia and arrhythmias

after pamidronate has been reported (Kadar, Rush et al. 2004). Pamidronate may cause renal toxicity in dogs, but it is thought this can be minimized or avoided by infusing the drug over at least 2 hours. Anemia, thrombocytopenia and granulocytosis have been reported in humans.

Reproductive/Nursing Safety

In pregnant humans, the FDA as a category **D** drug (*There is evidence of human fetal risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.*) Pamidronate has produced both maternal and embryo/fetal toxicity in laboratory animals when given at dosages therapeutically used in human patients. If it is used in pregnant veterinary patients, informed consent by the owner accepting the risks to both mother and offspring is recommended.

It is unknown if pamidronate is excreted into milk. Use with caution in nursing mothers.

Overdosage/Acute Toxicity

Overdosage of pamidronate may cause hypocalcemia, including tetany. Should this occur, treat with short-term, intravenous calcium.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pamidronate and may be of significance in veterinary patients:

- **CALCIUM-AFFECTING DRUGS** (e.g., furosemide, corticosteroids): Pamidronate must be used carefully (with monitoring) when used in conjunction with other drugs that can affect calcium
- **NEPHROTOXIC DRUGS** (e.g., cisplatin, aminoglycosides): Use with caution, potential for increased risk for nephrotoxicity

Laboratory Considerations

No specific laboratory interactions or considerations noted.

Doses**■ DOGS:**

- a) For refractory hypercalcemia: 1 mg/kg IV given over 2 hours in 250 mL of normal saline every 4 weeks. (Chun 2007c)
- b) For control of hypercalcemia: Treat each patient individually and if possible remove the underlying cause. If parenteral saline, furosemide and corticosteroids do not resolve the issue then bisphosphonates can be considered for more chronic control of hypercalcemia. Pamidronate 1.3–2 mg/kg in 150 mL of 0.9% saline with a 2 hour IV infusion; can repeat in 1–3 weeks. (Chew, Schenck et al. 2003)
- c) For treatment of cholecalciferol-induced toxicosis: 0.65–2 mg/kg in 0.9% NaCl on days 1 and 4 post-ingestion (Rumbeiha, Fitzgerald et al. 2000)
- d) For attempting to reduce bone pain associated with osteosarcoma in combination with an NSAID: 1–2 mg/kg; diluted into 250 mL of 0.9% sodium chloride and administered as a CRI over 2 hours every 28 days. (Fan and de Lorimier 2003), (Fan, de Lorimier et al. 2007)
- e) For calcipotriene toxicosis: 1.3–2 mg/kg slow IV infusion. In most cases, a single dose will lower calcium levels back to normal levels. Recommended to monitor calcium levels daily for at least 10 days after they have returned to normal. (Gwaltney-Brant 2003)

■ CATS:

- a) For control of hypercalcemia: 1.5–2 mg/kg IV (from a retrospective study of 2 cats). (Hostutler, Chew et al. 2005)

Monitoring

- Renal function (serum creatinine, etc.) and hydration status should be monitored before treating and prior to each dose
- Serum calcium, phosphate, magnesium, potassium
- CBC; baseline and continued if ongoing treatment
- Urinalysis

Client Information

- The medication must be given in an inpatient setting.
- Clients should understand the costs for the medication, care, and monitoring associated with its use.

Chemistry/Synonyms

Pamidronate disodium a bisphosphonate inhibitor of bone resorption occurs as a white, crystalline powder that is soluble in water and practically insoluble in organic solvents.

Pamidronate may also be known as: ADP sodium, AHPBP sodium, GCP-23339A, *Aminomux*®, *Aredia*®, *Aredronet*®, *Ostepam*®, or *Pamidran*®.

Storage/Stability/Compatibility

Do not store at temperatures greater than 30°C (86°F).

Once the lyophilized powder for injection is reconstituted (10 mL) with sterile water for injection, it may be stored in the refrigerator for 24 hours. Be sure drug is completely dissolved before withdrawing into syringe.

Do not mix pamidronate with any intravenous fluid containing calcium (e.g., Ringer's). It is recommended to use a dedicated IV solution (0.45% or 0.9% NaCl, or D₅W) and intravenous line.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

HUMAN-LABELED PRODUCTS:

Pamidronate Disodium (IV infusion) Lyophilized Powder for Injection: 30 mg & 90 mg with 470 mg mannitol in vials; *Aredia*® (Novartis); generic (Sandoz); (Rx)

Pamidronate Disodium Injection: 3 mg/mL, 6 mg/mL & 9 mg/mL (may contain mannitol) in 10 mL vials; generic; (Rx)

PANCRELIPASE

(pan-kree-*lih*-pase) Viokase®

PANCREATIC ENZYMES

Prescriber Highlights

- ▶ Pancreatic enzymes used to treat exocrine pancreatic enzyme deficiency or to test for pancreatic insufficiency secondary to chronic pancreatitis
- ▶ Contraindications: Hypersensitivity to pork products
- ▶ Adverse Effects: High doses may cause GI distress
- ▶ Avoid inhalation of powder; may cause skin irritation; wash off if gets on hands

Uses/Indications

Pancrelipase is used to treat patients with exocrine pancreatic enzyme deficiency. It may also be used in the attempt to test for pancreatic insufficiency secondary to chronic pancreatitis.

Pharmacology/Actions

The enzymes found in pancrelipase help to digest and absorb fats, proteins, and carbohydrates.

Contraindications/Precautions/Warnings

Pancrelipase products are contraindicated in animals that are hypersensitive to pork proteins.

Do not inhale the powder or bronchial/lung irritation can occur. Avoid contact with mucous membranes or skin.

Adverse Effects

High doses may cause GI distress (diarrhea, cramping, nausea). Concentrated pancreatic enzymes can cause oral or esophageal ulcers; follow dosing with food or water.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

These enzymes are unlikely to be excreted in maternal milk or pose risk to offspring.

Overdosage/Acute Toxicity

Overdosage may cause diarrhea or other intestinal upset. The effects should be temporary; treat by reducing dosage and supportively if diarrhea is severe.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pancrelipase and may be of significance in veterinary patients:

- **ANTACIDS (magnesium hydroxide, calcium carbonate):** May diminish the effectiveness of pancrelipase
- **CIMETIDINE (or other H₂ antagonists):** May increase the amount of pancrelipase that reaches the duodenum

Doses

■ DOGS:

For pancreatic exocrine insufficiency:

- 1–1.5 teaspoonsful with each meal mixed with food. Mix with food thoroughly and allow to stand for 15–20 minutes before feeding. Dosage should be adjusted as necessary. Best results are usually obtained by feeding small meals frequently (at least 3 times per day). (Package Insert; *Viokase*®-V Powder—Fort Dodge)
- 1/2–2 teaspoonsful PO with each meal. (Williams 2000)
- 1–2 teaspoonsful of powder or finely crushed nonenteric-coated tablets to each of two meals of balanced canine ration. It is not necessary to incubate the enzyme preparation before feeding. Tailor regimen to maintain optimal body weight. (Bunch 2003)
- Maintenance dose is usually 1 teaspoonful per meal. (Wester-marck, Wiberg et al. 2005)

■ CATS:

Note: Cats reportedly “hate” the taste of the powder and may be more easily dosed using solid dosage forms (enteric-coated tablets or compounded capsules made from powder or crushed tablets). If using these products, be certain that the cat follows the tablets with water or food to reduce the risk for esophageal damage. It has also been reported that some cats will eat food mixed with one brand of veterinary powder and refuse another.

For pancreatic exocrine insufficiency:

- a) 0.5–0.75 teaspoonsful with each meal mixed with food. Mix with food thoroughly and allow it to stand for 15–20 minutes before feeding. Dosage should be adjusted as necessary. Best results are usually obtained by feeding small meals frequently (at least 3 times per day). (Package Insert; *Viokase®-V Powder*—Fort Dodge)
- b) 1 teaspoonful of powder or finely crushed nonenteric-coated tablets to each of two meals of balanced feline ration. Cats that refuse to eat food treated with powder may be dosed with capsules filled with powder or crushed non-enteric coated tablets. It is not necessary to incubate the enzyme preparation before feeding. Tailor regimen to maintain optimal body weight. (Bunch 2003)
- c) 0.5 teaspoonsful of powder per meal. (Westermarck, Wiberg et al. 2005)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: For gastric trichobezoars: 1 teaspoonful (5 mL) pancrelipase powder plus 3 teaspoonsful (15 mL) of yogurt; let stand for 15 minutes, then give 2–3 mL PO q12h. Questionable efficacy for removing “hairballs”; but might help dissolve the protein matrix surrounding hair. (Ivey and Morrissey 2000)

■ BIRDS:

For pancreatic exocrine insufficiency (used in birds that are polyphagic “going light”, passing whole seeds, and slow in emptying crops):

- a) 1/8 tsp per kg. Mix with moistened feed or administer by gavage. Incubate with food for 15 minutes prior to gavage. (Clubb 1986)

Monitoring

- Animal's weight
- Stool consistency, frequency

Client Information

- Powder spilled on hands should be washed off or skin irritation may develop; do not allow powder to contact eyes
- Avoid inhaling powder; causes mucous membrane irritation and may trigger asthma attacks in susceptible individuals.

Chemistry/Synonyms

Pancrelipase contains pancreatic enzymes, primarily lipase but also amylase and protease, and is obtained from the pancreas of hogs. Each mg of pancrelipase contains not less than 24 USP Units of lipase activity, not less than 100 USP Units of protease activity, and not less than 100 USP Units of amylase activity. When compared on a per weight basis, pancrelipase has at least 4 times the trypsin and amylase content of pancreatin, and at least 12 times the lipolytic activity of pancreatin.

Pancrelipase may also be known as pancrelipasa, *Epizyme®*, *Panakare®*, *Pancrepowder Plus®*, *Pancreved®*, *Pancrezyme®*, and *Viokase®*.

Storage/Stability

Unless otherwise recommended by the manufacturer, store at room temperature in a dry place in tight containers. When present in quantities greater than trace amounts, acids will inactivate pancrelipase.

Dosage Forms/Regulatory Status

Note: There are several dosage forms (both human and veterinary-label) available containing pancrelipase, including oral capsules, oral delayed-release capsules, tablets, and delayed-released tablets. Most small animal practitioners feel that the oral powder is most effective in dogs.

VETERINARY-LABELED PRODUCTS:

Pancrelipase Powder containing (approximately) per teaspoonful (2.8 grams): 71,400 Units lipase; 388,000 Units protease; 460,000 Units amylase; in 8 oz bottle; *Viokase®-V Powder* (Fort Dodge), *Pancrezyme® Powder* (Virbac); *Pancrepowder Plus®* (Butler), *Pancreved® Powder* (Vedco), *Epizyme® Powder* (V.E.T.), *Panakare® Plus Powder* (Neogen), (Rx). Labeled for use in dogs and cats.

HUMAN-LABELED PRODUCTS:

There are capsules, tablets, and powders available containing lipase, protease, and amylase in varying units available for human consumption from many distributors.

PANCURONIUM BROMIDE

(pan-kue-roe-nee-um) Pavulon®

NON-DEPOLARIZING NEUROMUSCULAR BLOCKER

Prescriber Highlights

- Non-depolarizing neuromuscular blocker used as an adjunct to general anesthesia
- Contraindications: Known hypersensitivity. Extreme Caution: Myasthenia gravis
- Caution: Renal dysfunction, hepatic or biliary disease; patients where tachycardias may be deleterious
- No analgesic or sedative/anesthetic actions
- Adverse Effects: Slight elevations in cardiac rate & blood pressure, hypersalivation (if not pretreated with an anticholinergic agent), prolonged or profound muscular weakness, & respiratory depression. Very Rarely: Histamine release with resultant hypersensitivity reaction
- Drug Interactions

Uses/Indications

Pancuronium is indicated as an adjunct to general anesthesia to produce muscle relaxation during surgical procedures or mechanical ventilation and to facilitate endotracheal intubation.

Pharmacology/Actions

Pancuronium is a nondepolarizing neuromuscular blocking agent and acts by competitively binding at cholinergic receptor sites at the motor endplate, inhibiting the effects of acetylcholine. It is considered 5 times as potent as d-tubocurarine and 1/3 as potent as vecuronium (some sources say that pancuronium is equipotent with vecuronium in animals). It has little effect on the cardiovascular system other than increasing heart rate slightly, and only rarely does it cause histamine release.

Pharmacokinetics

After intravenous administration, muscle relaxation sufficient for endotracheal intubation occurs generally within 2–3 minutes, but is dependent on the actual dose administered. Duration of action may persist 30–45 minutes, but this again is dependent on the dose. Additional doses may slightly increase the magnitude of the blockade and will significantly increase the duration of action.

In humans, pancuronium is approximately 87% bound to plasma proteins, but it may be used in hypoalbuminemic patients. Activity is non-affected substantially by either plasma pH or carbon dioxide levels.

The half-life in humans ranges from 90–161 minutes. Approximately 40% of the drug is excreted unchanged by the kidneys. The remainder is excreted in the bile (11%) or metabolized by the liver. In patients with renal failure, plasma half-lives are doubled; atracurium may be a better choice for these patients.

Contraindications/Precautions/Warnings

Pancuronium is contraindicated in patients hypersensitive to it. It should be used with caution in patients with renal dysfunction, or where tachycardias may be deleterious. Lower doses may be necessary in patients with hepatic or biliary disease. Pancuronium has no analgesic or sedative/anesthetic actions. In patients with myasthenia gravis, neuromuscular blocking agents should be used with extreme caution, if at all.

Adverse Effects

Adverse reactions seen with pancuronium include: slight elevations in cardiac rate and blood pressure, hypersalivation (if not pretreated with an anticholinergic agent), occasional rash (humans), and prolonged or profound muscular weakness and respiratory depression. Very rarely, pancuronium will cause substantial histamine release with resultant hypersensitivity reactions.

Reproductive/Nursing Safety

In humans, the FDA categorizes this drug as category **C** for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*) In a separate system evaluating the safety of drugs in canine and feline pregnancy (Papich 1989), this drug is categorized as class: **B** (*Safe for use if used cautiously. Studies in laboratory animals may have uncovered some risk, but these drugs appear to be safe in dogs and cats or these drugs are safe if they are not administered when the animal is near term.*)

It is not known whether these drugs are excreted in maternal milk.

Overdosage/Acute Toxicity

Monitoring muscle twitch response to peripheral nerve stimulation can minimize overdosage possibilities. Increased risks of hypotension and histamine release occur with overdoses, as well as prolonged duration of muscle blockade.

Besides treating conservatively (mechanical ventilation, O₂, fluids, etc.), reversal of blockade may be accomplished by administering an anticholinesterase agent (edrophonium, physostigmine, or neostigmine) with an anticholinergic (atropine or glycopyrrolate). A suggested dose for neostigmine is 0.06 mg/kg IV after atropine 0.02 mg/kg IV.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pancuronium and may be of significance in veterinary patients:

- **AZATHIOPRINE:** May reverse pancuronium's neuromuscular blocking effects
- **AMINOGLYCOSIDES** (**gentamicin**, etc.): May enhance the neuromuscular blocking activity of pancuronium
- **LINCOSAMIDES:** (**clindamycin**, etc.): May enhance the neuromuscular blocking activity of pancuronium
- **MAGNESIUM SULFATE** or **HCl:** May enhance the neuromuscular blocking activity of pancuronium
- **QUINIDINE:** May enhance the neuromuscular blocking activity of pancuronium
- **SUCCINYLCHOLINE:** Other muscle relaxant drugs may cause a synergistic or antagonistic effect. Succinylcholine may speed the onset of action and enhance the neuromuscular blocking actions of pancuronium. Do not give pancuronium until succinylcholine effects have subsided.
- **THEOPHYLLINE:** May inhibit or reverse the neuromuscular blocking action of pancuronium and possibly induce arrhythmias
- **TRICYCLIC ANTIDEPRESSANTS** (e.g., **clomipramine**, **amitriptyline**): Increased risk for cardiac arrhythmias when used with halothane anesthesia

Doses

■ DOGS:

- a) As a paralytic during mechanical ventilation: 0.05–0.1 mg/kg IV; lasts about an hour, must give sedation as well (Carr 2003)
- b) 0.044–0.11 mg/kg IV; higher dose used initially; lower doses required if repeated doses are necessary (Mandsager 1988)
- c) On occasions when anesthesia maintenance with IV or regional techniques are not adequate to prevent spontaneous movement and the addition of inhalational agents results in severe hypotension (not corrected with fluid therapy): 0.02–0.04 mg/kg IV provides 30–45 minutes of muscle relaxation. (Day 2005)

■ CATS:

- a) 0.044–0.11 mg/kg IV; higher dose used initially; lower doses required if repeated doses are necessary (Mandsager 1988)

■ RABBITS, RODENTS, SMALL MAMMALS:

- a) Rabbits: 0.1 mg/kg IV (Ivey and Morrissey 2000)

■ SWINE:

- a) 0.11 mg/kg IV (Muir)

Monitoring

- Level of neuromuscular blockade
- Cardiac rate

Client Information

- This drug should only be used by professionals familiar with using neuromuscular blocking agents in a supervised setting with adequate ventilatory support

Chemistry/Synonyms

A synthetic, non-depolarizing neuromuscular blocker, pancuronium bromide occurs as a white, odorless, bitter-tasting, hygroscopic, fine powder. It has a melting point of 215°C and one gram is soluble in 100 mL of water; it is very soluble in alcohol. Acetic acid is used to adjust the commercially available injection to a pH of approximately 4.

Pancuronium bromide may also be known as: NA-97, Org-NA-97, or pancuronii bromidum.

Storage/Stability/Compatibility

Pancuronium injection should be stored under refrigeration (2–8°C), but, according to the manufacturer, it is stable for 6 months at room temperature.

Do not store pancuronium in plastic syringes or containers as it may be adsorbed to plastic surfaces. It may be administered in plastic syringes, however.

It is recommended that pancuronium not be mixed with barbiturates, as a precipitate may form, although data conflicts on this point. No precipitate was seen when pancuronium was mixed with succinylcholine, meperidine, neostigmine, gallamine, tubocurarine, or promethazine.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 2 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Pancuronium Bromide for Injection: 1 mg/mL in 10 mL vials; 2 mg/mL in 2 mL and 5 mL amps; generic; (Rx)

PANTOPRAZOLE

(pan-toe-prah-zohl) Protonix®, Pantoloc®

PROTON PUMP INHIBITOR**Prescriber Highlights**

- ▶ Proton pump inhibitor similar to omeprazole; also available in IV dosage form
- ▶ May be useful in treating or preventing gastric acid-related pathologies in dogs, cats, foals & camelids
- ▶ Relatively limited research & experience in veterinary medicine, particularly when compared with omeprazole
- ▶ Appears well tolerated

Uses/Indications

Pantoprazole may be useful in treating or preventing gastric acid-related pathologies in dogs, cats, foals and camelids, particularly when the intravenous route is preferred. Pantoprazole is available in both intravenous and oral tablet (delayed-release) formulations. One study (Bersenas, Mathews et al. 2005) performed in dogs, comparing the gastric pH effects of intravenous pantoprazole with oral omeprazole, intravenous ranitidine, and intravenous famotidine, found at the dosages used, that pantoprazole was more effective than ranitidine, but similar to famotidine, and that oral omeprazole was more effective in maintaining intragastric pH >3 for a longer period than pantoprazole.

Pantoprazole has been shown to directly reduce *in vitro* counts of *H. pylori* and is used in some *H. pylori* treatment protocols for humans.

Pharmacology/Actions

Pantoprazole is a substituted benzimidazole, similar to omeprazole and the other proton pump inhibitors (PPIs). At the secretory surface of gastric parietal cells, pantoprazole forms a covalent bond at two sites of the H⁺/K⁺ ATPase (proton pump) enzyme system. There it inhibits the transport of hydrogen ions into the stomach. Pantoprazole reduces acid secretion during both basal and stimulated conditions.

Pharmacokinetics

No specific information was located for pantoprazole pharmacokinetics in dogs or cats. In neonatal foals, intragastric (IG) administered pantoprazole bioavailability was 41% and drug was detected in plasma within 5 minutes of administration. Mean hourly gastric pH was increased for 2–24 hours versus untreated foals after either IV or IG administration, but IV administration increased pH significantly greater than IG administration, presumably due to low GI bioavailability (Ryan, Sanchez et al. 2005).

In humans, it is rapidly absorbed after oral administration with an oral bioavailability of 77%. Food can reduce the rate of absorption, but does not appear to affect the extent of absorption. On average, 51% of gastric acid secretion is inhibited at 2.5 hours after a single dose and 85% is inhibited after the seventh day of daily administration. Protein binding is 98%, primarily to albumin. The drug is metabolized in the liver, primarily by CYP2C19 isoenzymes. CYP3A4, 2D6, 2C9, or 1A2 are minor components of pantoprazole biotransformation; pantoprazole does not appear to clinically affect (either induce or inhibit) the metabolism of other drugs using these isoenzymes for biotransformation. Metabolites of pantoprazole do not appear to have pharmacologic activity. Elimination half-life for both oral and IV administration is only about an hour, but the drug's pharmacologic action can persist for 24 hours or more, presumably due to irreversible binding at the receptor site. About 71% of a dose is excreted as metabolites in the urine, with the remainder in the feces as metabolites and unabsorbed drug.

Contraindications/Precautions/Warnings

Pantoprazole is contraindicated in patients known to be hypersensitive to it or other substituted benzimidazole PPIs.

Parenteral pantoprazole must be administered IV; do not give IM or SQ. Reconstituted injection (4 mg/mL) must be administered intravenously over not less than 2 minutes.

Adverse Effects

Use has been limited in small animals and an adverse effect profile is not well established; however, the drug appears to be tolerated well.

In humans, the most commonly reported adverse effects are diarrhea and headache. Hyperglycemia has been reported in about 1% of patients. Proton pump inhibitors have been associated with an increased risk of developing community-acquired pneumonia in humans. Injection site reactions (thrombophlebitis, abscess) have occurred with IV administration.

Reproductive/Nursing Safety

When pantoprazole was dosed in rats (98X human dose) and rabbits (16X), no effects on fertility or teratogenic effects were noted. In humans, the FDA categorizes pantoprazole as category **B** for use during pregnancy (*Animal studies have not yet demonstrated risk to the fetus, but there are no adequate studies in pregnant women; or animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus in the first trimester of pregnancy, and there is no evidence of risk in later trimesters.*)

Pantoprazole and its metabolites have been detected in milk, but it should be relatively safe to use in nursing veterinary patients.

Overdosage/Acute Toxicity

There is limited information available. A single oral dose of 887 mg/kg was lethal in dogs. Acute toxic signs included ataxia, hypotactivity, and tremor. In humans, single oral overdoses of up to 600 mg have been reported without adversity. In the event of a large overdose, it is recommended to contact an animal poison control center for guidance.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving pantoprazole and may be of significance in veterinary patients:

- **DRUGS REQUIRING DECREASED GASTRIC PH FOR OPTIMAL ABSORPTION** (e.g., **ketoconazole**, **itraconazole**, **iron**, **ampicillin esters**): Pantoprazole may decrease drug absorption
- **SUCRALFATE**: May decrease bioavailability of orally administered pantoprazole
- **WARFARIN**: Pantoprazole may increase anticoagulant effect

Laboratory Considerations

- Although not likely to be important for veterinary patients, pantoprazole may cause false-positive results for urine screening tests for THC (tetrahydrocannabinol)

Doses

■ DOGS / CATS:

- a) Dogs: For intravenous treatment of stress-related mucosal disease: 0.7–1 mg/kg IV once daily. (Bateman 2003)

■ HORSES:

- a) For gastric acid suppression in neonatal foals: 1.5 mg/kg IV once daily. **Note:** From an experimental study evaluating the pharmacokinetics and pharmacodynamics in normal neonatal foals. Further studies are required to investigate the use of this drug in critically ill patients. (Ryan, Sanchez et al. 2005)

Monitoring

- Efficacy
- Adverse effects (vomiting, diarrhea, injection site reactions if used IV)

Client Information

- Tablets must be given whole; do not split or crush
- If patient develops bloody diarrhea, tarry-black stools, or vomits blood, contact veterinarian immediately
- Contact veterinarian if vomiting or diarrhea persist or are severe

Chemistry/Synonyms

Pantoprazole sodium sesquihydrate occurs as a white to off-white crystalline powder and is racemic. It is freely soluble in water and very slightly soluble in phosphate buffer at a pH of 7.4. Stability of aqueous solutions is pH dependent. At room temperature, solutions of pH 5 are stable for about 3 hours; at a pH of 7.8, 220 hours.

Pantoprazole may also be known as BY-1023, or SKF-96022. International trade names include: *Controloc*®, *Pantoloc*®, *Zurcal*, *Pantozol*®, *Pantop*®, *Protonix*®, *Protium*®, *Somac-MA*®, and many others.

Storage/Stability/Compatibility

Delayed-release tablets should be stored between 15–30°C.

The powder for injection should be stored protected from light at 20–25°C; excursions are permitted to 15–30°C. For a 2-minute IV infusion; reconstitute with 10 mL of 0.9% sodium chloride injection. To prepare the injection for a 15-minute IV infusion, reconstitute with 10 mL of 0.9% sodium chloride injection, then dilute further with 100 mL of D5W, 0.9% sodium chloride or lactated Ringer's injection to a final concentration of approximately 0.4 mg/mL. Reconstituted solutions (10 mL) are stable for up to 2 hours at room temperature. If further diluted (per 15 minute infusion), it is stable for up to 22 hours at room temperature. Reconstituted solutions do not need to be protected from light. Do not freeze. Do not use the IV solution if discoloration or precipitates are seen; should these be observed during the infusion, stop immediately.

Pantoprazole injection is **not compatible** with midazolam and may not be compatible with solutions containing zinc.

Dosage Forms/Regulatory Status

VETERINARY-LABELED PRODUCTS: None

The ARCI (Racing Commissioners International) has designated this drug as a class 5 substance. See the appendix for more information.

HUMAN-LABELED PRODUCTS:

Pantoprazole Sodium Delayed-Release Tablets: 20 mg (as base) & 40 mg (as base); *Protonix*® (Wyeth-Ayerst); (Rx)

Pantoprazole Powder (freeze-dried) for Injection: 40 mg (as base)/vial; *Protonix I.V.*® (Wyeth-Ayerst); (Rx)

PARAPOX OVIS VIRUS IMMUNOMODULATOR

(pair-ah-poks oh-vis) Zylexis®

IMMUNOSTIMULANT

Prescriber Highlights

- Biologic immunostimulant labeled for use in healthy horses of 4 months of age & older as an aid in reducing upper respiratory disease caused by equine herpesvirus types 1 & 4
- Limited published information available on safety & efficacy

Uses/Indications

Parapox ovis virus immunomodulator is commercially available in the USA labeled for “use in healthy horses of 4 months of age and older as an aid in reducing upper respiratory disease caused by equine herpesvirus types 1 and 4.”

A parapoxvirus product (*Baypamun*®) is reportedly available in some European countries for use in small animals.

Pharmacology/Actions

Parapox ovis is the virus responsible for “orf” in sheep, a contagious pustular dermatitis. The virus is inactivated in the commercial product. Parapoxvirus products are so-called “paramunity inducers” and are believed to prevent viral infection by pathogenic viruses via viral interference. By “infecting” host cells with a defective (non-replicating) virus, interference with infection by the pathogenic virus can occur. Postulated mechanisms of action include induction of interferons, cytokines and colony-stimulating factors, and activation of natural killer cells.

Pharmacokinetics

Effects on the immune system are reported to occur 4–6 hours after treating; effects persist for 1–2 weeks.

Contraindications/Precautions/Warnings

Do not be use in patients with prior hypersensitivity to the agent. The manufacturer warns that in the case of an anaphylactic reaction, administer epinephrine or equivalent.

Reproductive/Nursing Safety

No information was located.

Adverse Effects

No adverse effects are listed in the package insert, but anaphylaxis is possible.

Overdosage/Acute Toxicity

No information was located.

Drug Interactions

None noted

Laboratory Considerations

None identified

Doses■ **HORSES:**

- a) For an aid in reducing upper airway disease caused by herpesvirus types 1 and 4: After reconstituting with the sterile diluent provided, administer 2 mL IM. Repeat doses on days 2 and 9 following the initial dose. Retreatment is recommended during subsequent disease episodes or prior to stress inducing situations. (Label information; *Zylexis*®—Pfizer)

Monitoring

- Clinical Efficacy (respiratory infection improvement)

Chemistry/Synonyms

Zylexis® is provided commercially as a freeze-dried inactivated (killed) virus component with separate 2 mL vial of sterile diluent.

Parapox ovis virus immunomodulator may also be known as: PPOV, PIND-ORF, or *Baypamune*® and *Zylexis*®.

Storage/Stability

Zylexis® should be stored refrigerated (2–8°C), but not be frozen. After reconstituting, entire contents should be used.

Dosage Forms/Regulatory Status**VETERINARY-LABELED PRODUCTS:**

Parapox Ovis Virus Immunomodulator Injection in boxes of 5-single dose vials for reconstitution with 5-2mL vials of sterile diluent; *Zylexis*® (Pfizer); Labeled for use in horses.

Note: This product is a USDA-licensed biologic and is not approved by the FDA. The label for *Zylexis*® states that it should not be administered to horses within 21 days of slaughter.

HUMAN-LABELED PRODUCTS: None**PAREGORIC**

(par-eh-gore-ik); Camphorated Tincture of Opium

OPIATE ANTIDIARRHEAL**Prescriber Highlights**

- Opiate GI motility modifier for diarrhea
- Contraindications: Known hypersensitivity to narcotic analgesics, patients receiving monoamine oxidase inhibitors (MAOIs), diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract
- Caution: Respiratory disease, hepatic encephalopathy, hypothyroidism, severe renal insufficiency, adrenocortical insufficiency (Addison's), head injuries, or increased intracranial pressure, acute abdominal conditions (e.g., colic), & in geriatric or severely debilitated patients
- Adverse Effects: DOGS: Constipation, bloat, & sedation. Potential for: paralytic ileus, toxic megacolon, pancreatitis, & CNS effects. CATS: Use is controversial, may exhibit excitatory behavior. HORSES: With GI bacterial infection, may delay the disappearance of the microbe from the feces & prolong the febrile state
- Dose carefully in small animals; do not confuse with opium tincture
- Paregoric is a C-III controlled substance

Uses/Indications

Paregoric is occasionally used as a motility modifiers for animals diarrhea. Opiates as antidiarrheal treatments in cats is controversial and many clinicians do not recommend their use in this species.

Pharmacology/Actions

Among their other actions, opiates inhibit GI motility and excessive GI propulsion. They also decrease intestinal secretion induced by cholera toxin, prostaglandin E₂ and diarrheas caused by factors in which calcium is the second messenger (non-cyclic AMP/GMP mediated). Opiates may also enhance mucosal absorption.

Pharmacokinetics

The morphine in paregoric is absorbed in a variable fashion from the GI tract. It is rapidly metabolized in the liver and serum morphine levels are considerably less than when morphine is administered parenterally.

Contraindications/Precautions/Warnings

All opiates should be used with caution in patients with hypothyroidism, severe renal insufficiency, adrenocortical insufficiency, (Addison's), in geriatric or those severely debilitated. Opiate antidiarrheals are contraindicated in cases where the patient is hypersensitive to narcotic analgesics, those receiving monoamine oxidase inhibitors (MAOIs), and with diarrhea caused by a toxic ingestion until the toxin is eliminated from the GI tract.

Opiate antidiarrheals should be used with caution in patients with head injuries or increased intracranial pressure and acute abdominal conditions (e.g., colic), as it may obscure the diagnosis or clinical course of these conditions. It should be used with extreme caution in patients suffering from respiratory disease or acute respiratory dysfunction (e.g., pulmonary edema secondary to smoke inhalation). Opiate antidiarrheals should be used with extreme

caution in patients with hepatic disease with CNS clinical signs of hepatic encephalopathy; hepatic coma may result.

Adverse Effects

In dogs, constipation, bloat, and sedation are the most likely adverse reactions encountered when usual doses are used. Potentially, paralytic ileus, toxic megacolon, pancreatitis, and CNS effects could be seen.

Use of antidiarrheal opiates in cats is controversial; this species may react with excitatory behavior.

Opiates used in horses with acute diarrhea (or in any animal with a potentially bacterial-induced diarrhea) may have a detrimental effect. Opiates may enhance bacterial proliferation, delay the disappearance of the microbe from the feces, and prolong the febrile state.

Reproductive/Nursing Safety

Opium tincture is classified as category C for use during pregnancy (*Animal studies have shown an adverse effect on the fetus, but there are no adequate studies in humans; or there are no animal reproduction studies and no adequate studies in humans.*)

Safe use of paregoric during breastfeeding in women has not been established; use with caution in nursing animals.

Overdosage/Acute Toxicity

Acute overdosage of the opiate antidiarrheals could result in CNS, cardiovascular, GI, or respiratory toxicity. Because the opiates may significantly reduce GI motility, absorption from the GI may be delayed and prolonged. For more information, refer to the meperidine and morphine monographs found in the CNS section. Naloxone may be necessary to reverse the opiate effects.

Drug Interactions

The following drug interactions have either been reported or are theoretical in humans or animals receiving opiate antidiarrheals and may be of significance in veterinary patients:
